ENCYCLOPÆDIA BRITANNICA.

OROBIO, BALTASAR (sometimes called ISAAC DE CASTRO), a celebrated Spanish Jew, born in the early part of the seventeenth century, and educated in Judaism by his parents, who outwardly professed themselves Catholics. Orobio studied the scholastic philosophy as taught in Spain, and became so skilled in it that he was appointed professor of metaphysics in the university of Salamanca. Afterwards, however, having applied himself to the study of physic, he practised that art with success at Seville, till, being accused of Judaism, he was thrown into the prison of the Inquisition, and suffered the most dreadful cruelties, in order to extort a confession. After a confinement of three years, the inquisitors, finding themselves baffled by his perseverance in denying his religion, ordered his wounds to be cured, and discharged him. As soon as he had obtained his liberty, he proceeded to France, and was made professor of physic at Toulouse. He resided for some time in this city, still outwardly professing the Catholic religion; but at last, weary of dissembling, he repaired to Amsterdam, where he was circumcised, took the name of Isaac, and professed Judaism, still continuing, however, to practise physic, in which he was much esteemed. Upon the publication of Spinoza's work, he is said to have soon discovered the weak points in the system of the great pantheist; and when Bredenburg's answer to it appeared, Orobio, being persuaded that the writer, in refuting Spinoza, had also admitted some principles which tended to atheism, took up his pen against both, and in 1684 published a piece entitled *Certamen Philosophicum*, characterized by great acuteness and power. But the dispute in which he engaged with the celebrated Philip Limborch against the Christian religion made the greatest noise. In this he exerted the utmost force of his metaphysical genius, and conducted himself with great temper. The three papers which he wrote on the occasion were afterwards printed by his antagonist in an account which he published of the controversy, under the title of *Amica Collatio cum Judæo*. Orobio died in 1687. (See *Israel Avenged*, translated and answered by Dr M'Caul, 8vo, London, 1839.)

ORONTES, the most famous river in ancient Syria, rises at the foot of Anti-Libanus, winds along in a northerly course for 200 miles, and then taking a sudden bend near Antioch in a south-westerly direction, flows over a space of 40 miles to the Mediterranean Sea. The notices of its fame in classical times are chiefly found in Strabo. His account is, that the river flowed for a part of its course under ground; that its name was derived from a certain Orontes who built a bridge over it; and that it had been originally called *Typhon*, from a fabulous dragon which, in his flight for shelter, wore out the channel of the stream with his trail, and opened up the fountain-head by his plunge into the earth. In the present day, the Orontes dwindles down into a paltry rivulet during the heat of summer. In winter, however, it becomes swollen by the melting of the mountain snows, and whirls along its deep and narrow bed with a resistless rapidity which has gained for it its modern name of *Aasi* ("The Rebel").

OROSHAZA, a town of Hungary, county of Bekes, 40 miles N.E. of Szegedin. An active trade is carried on in cattle, sheep, and pigs, of which large numbers are reared in the vicinity. The wine made in the neighbourhood is the best in the county. Pop. (1851) 10,915.

OROSIUS, PAULUS, a learned presbyter of Spain, born towards the close of the fourth century at Tarragona, on the shores of the Mediterranean. After spending some time in study in his native country, he passed over to Africa to enjoy the instructions of the celebrated St Augustine, Bishop of Hippo Regius. How long he remained there before returning to Spain cannot be precisely ascertained. It is known, however, that Orosius was despatched by the Spanish bishops Eutropius and Paul (A.D. 414) to consult St Augustine on several abstruse points of doctrine then under dispute. On this occasion Orosius wrote *Consultatio sive Commonitorium Orosii ad Augustinum de errore Priscillianistarum et Origenistarum;* to which Augustine published the reply, *Ad Orosium contra Priscillianistas et Origenistas;* both of which pieces are to be found in the works of the Bishop of Hippo. During the following year Orosius set out for Palestine, at the recommendation of Augustine, to consult St Jerome, the best scholar and critic of the early church, then engaged on his Latin version of the Scriptures. The active intelligence, gentle bearing, and calm modesty of the young Spaniard, won the heart of the great scholar, and he showed him as much kindness as Augustine

had done before him. While resident in Palestine, Orosius had occasion to break a lance with Pelagius. In a synod held at Jerusalem on the 30th July A.D. 415, the Spanish presbyter was called upon to oppose that heretic and his disciples, which led to the publication of the famous treatise *Apologia contra Pelagium de Arbitrii Libertate*, afterwards appended to the author's *History of the World*. On his way home to Spain in 416 A.D., Orosius took occasion, in accordance with his promise, to visit Augustine at Hippo. Rome had just been captured and pillaged a few years previously by the Visigoths, who were converts to Christianity. This gave rise to the calumnious assertion, industriously promulgated by the heathens of that time, that Christianity had been injurious rather than beneficial to mankind. Augustine took up his pen in defence of the cause; and, in his famous *De Civitate Dei*, showed, by an appeal to historical facts, that precisely the opposite was true. On this work the bishop was engaged when Orosius first visited him; and Augustine endeavoured to induce the zealous Spaniard to embark in a similar undertaking, and do for the facts of general history what he had done for the facts of the history of the church in his *City of God*. This was the origin of Orosius' well-known *Historiarum adversus Paganos Libri VII.*, dedicated to St Augustine. Part of it is said to have been put together in Africa; and it was probably completed about A.D. 416, the date at which the narrative closes. It is written with great force and brevity, and soon attained a wide popularity. It was lauded by popes, translated by kings, and read by all. The *editio princeps* of the History was printed at Vienna as early as 1471; but the best edition is unquestionably that of Havercamp, Lugd. Bat., 4to, 1738. A number of other pieces have been ascribed to Orosius, but no complete edition of his works has yet appeared. (For further information respecting Orosius, the reader may consult the works of J. W. Moller, 1689; of Dalmasses y Roz, 1702; of C. A. Haumann, 1732; of G. F. H. Beck, 1834; and of P. T. von Moerner, 1844.)

King Alfred transferred the substance of Orosius' History from the original Latin into Anglo-Saxon for the instruction of his people. Of this royal version three separate editions have been published in this country; one by Daines Barrington, with an English translation, 8vo, London, 1773, full of inaccuracies; another by B. Thorpe, with an English translation, 8vo, London, 1853, appended to Pauli's *Life of Alfred the Great* in Bohn's "Antiquarian Library;" and a third, with the English version only, but containing an introduction and valuable notes by Dr Bosworth, London, 1855.

OROTAVA, a town of the island of Teneriffe, capital of a district of the same name, is built on the slope of a hill on the N. coast, 1200 feet above the level of the sea. It is regularly laid out, the streets extending along the hill one behind the other. Of the two churches of Orotava, one is a handsome building with three naves, and contains a marble tabernacle brought from Genoa. There are also in the town two schools and an hospital. Pop. 8315. About 2 miles off stands a town called Puerto de la Orotava, with a harbour, which serves as the seaport of Orotava. By this a considerable trade is carried on; and it is from hence that the wines of the island are exported. Pop. 4600.

ORPHEUS, a celebrated poet and musician, who lived at such an early period that his history is involved in fable, and many doubt if we have any facts respecting him on which dependence can be placed. According to the common mythology, he was a native of Thrace, being born in a cave at Pimpleia, a city of Pieria, which was then included in Thrace (Schol. Apollon. i. 25; Strab. vii. 330, x. 471). He is said to have been son of Apollo, or of Œagrus, King of Thrace, and of the Muse Calliope (Diodor. ii. 64). He was the brother of Linus (Apollodor. ii. 4, 9), and the pupil of Musæus (Clemens. Strom. i., p. 332), or his master (Syncel., p. 156; Paus. x. 7, 1; Suid.) He is placed by Eusebius eighty-five years before the fall of Troy. He visited Egypt, and was there initiated in all the learning of the priests. When he returned to Thrace, he instituted the mysteries of Bacchus, which, according to Herodotus (ii. 81), included opinions which were afterwards promulgated by Pythagoras. He studied also under the Dactyli Idæi of Crete (Diodor. v. 64), and was the friend and companion of Cadmus, the founder of Thebes. He took a distinguished part in the Argonautic expedition, and saved his companions from the fascination of the Sirens by the charm of his golden lyre (Apollodor. i. 9, 25). On the death of his wife Eurydice, he is said to have visited the infernal regions, and, through the intercession of Proserpine, obtained permission from Pluto that Eurydice should return with him to earth, provided he would engage not to look on her till he reached the upper world. He broke his promise, and Eurydice instantly disappeared (i. 3, 2). A different version of the descent into Hades is given by Plato (*Symp.* and *Polit.*), who represents the gods as having imposed upon Orpheus by showing him only a phantasm of his lost wife, as a mark of their detestation of his cowardice in being afraid to die. How and where he died is variously stated. Some say that he died of grief for the loss of Eurydice; others allege that he was killed by lightning, because he revealed to man what the gods intended should be concealed from them; or that he was torn to pieces by the Mænades of Thrace for some disrespect shown to Bacchus. Olympus, Pangæus, and Hæmus are all named as the place of his catastrophe. The poets indicated the sweetness of his music by feigning that it was capable of moving the very stones and trees. Lucian tells a story of the head and lyre of Orpheus being thrown by the Thracian women into the Hebrus, and, as they floated down, the motion of the water brought them into contact, and the divine instrument gave forth strains of the most doleful and bewitching sweetness. The head and lyre having reached the island of Lesbos, the former was buried on the spot where the temple of Bacchus afterwards stood, and the lyre was long preserved in the temple of Apollo. According to Eratosthenes (*Catast.* 24), it was placed by Jupiter in the heavens, and formed the constellation called Lyra.

There can be no doubt that there was an early poet of this name, but Aristotle considered all the works which were circulated under his name as spurious (Cic., *De Nat. Deor.* i. 38); and Cicero ascribes them to Cercops, a Pythagorean, or to Onomacritus (Clemens, *l. c.*) The hymn to Jupiter, quoted by Stobæus (p. 40), is certainly very ancient, as it is alluded to by Aristotle (*De Mund. Op.*, t. i., p. 475), and is not to be confounded with the productions of the later Platonic school, which we have under the title of the Orphic Hymns. These hymns present a mixture of the theological ideas of the Greeks, Jews, and even Christians; so that there can be no doubt of the period in which they were written. The editions of the *Orphica* have been very various. That of Hermann, Leipsic, 8vo, 1805, is unquestionably the best. An English version of the Orphic Hymns, with a preliminary dissertation, was published by Thomas Taylor in 1787.

ORRERY, EARL OF. See BOYLE, *Charles*.

ORRERY. See PLANETARY MACHINES.

ORSOVA (*Old* and *New*), the name of two towns on the Danube, the former belonging to Austria, and the latter to Turkey. Old Orsova stands on the left bank of the river, 90 miles S.E. of Temesvar, in the Banat Military Frontier. It is fortified, and has manufactories of leather. Pop. 1000. New Orsova, which belongs to the province of Servia, stands on an island in the river W. of Old Orsova, and is strongly fortified. Pop. 2800. (See DANUBE.)

ORTELIUS, ABRAHAM, a celebrated geographer, called the Ptolemy of his time, was born at Antwerp in 1527.

He resided at Oxford in the reign of Edward VI.; came a second time into England in 1577; and is said to have persuaded Camden to write his *Britannica.* His *Theatrum Orbis Terrarum*, published at Antwerp in 1570, was the most complete work of the kind which had yet appeared, and gained him great reputation. He also wrote several other geographical works, the principal of which are, his *Synonymia Geographica*, Antwerp, 1578, and his *Thesaurus Geographicus*, Antwerp, 1594. He died at Antwerp in 1598.

ORTHEZ, a town of France, department of Lower Pyrenees, stands on a hill 892 feet above the sea, on the right bank of the Gave de Pau, 24 miles N.W. of Pau, and 37 E. of Bayonne. The town is regularly laid out and well built, having been recently much improved. The river is here crossed by an old Gothic bridge of four arches, with a tower in the centre. Among the public buildings is a handsome town-hall and an old parish church. On a height above the town stand the remains of the castle of Moncada, built by Gaston de Foix in 1240. These consist of a few dilapidated walls, with one lofty tower. Orthez contains a college and a court of the first instance. Manufactures of linen and woollen stuffs, leather, copper, and other articles are carried on. There is an active and extensive trade in hides, hams, wool, cattle, horses, timber, slates, marble, &c. Orthez was formerly a place of considerable importance, as it was the residence of the princes of Béarn until the end of the fifteenth century, when they removed to Pau. The castle of Moncada was at one time the residence of Jeanne d'Albret, Queen of Navarre, the mother of Henri IV., who established a Protestant college in the town. Orthez suffered much during the civil wars in France after the Reformation. Viscount d'Orthez, governor of the town, was one of the few who nobly refused to obey the royal order for the massacre of St Bartholomew. On the 27th of February 1814 a victory was gained by Wellington, with 37,000 troops, over Soult, with 40,000, in the vicinity of Orthez. In the retreat the French attempted, but unsuccessfully, to blow up the bridge over the Gave de Pau. Pop. 6619.

ORTHOGRAPHIC PROJECTION OF THE SPHERE, that in which the eye is supposed to be at an infinite distance. It is so called because the perpendiculars from any point of the sphere will all fall in the common intersection of the sphere with the plane of the projection.

ORTHOGRAPHY. See GRAMMAR.

ORTONA, a town of Naples, province of Abruzzo-Citra, on the shore of the Adriatic, 11 miles E. of Chiete. It contains a cathedral and several other churches; and gives its title to a bishop. There is a small harbour, by means of which an active trade is carried on in the wine grown in the vicinity, said to be the best in this part of Italy. Ortona occupies the site of the ancient town of the same name, which was the principal maritime town of the Frentani. Some ancient remains have been found here. Pop. 6000.

ORURO, a mining town of Bolivia, capital of a department of the same name, stands on a bare hill, 13,000 feet above the sea, on the right bank of the Desaguadero, where it falls into Lake Aullagus. The population has declined very much, and the town is surrounded by the ruins of houses that were once inhabited. Pop. 6000.

The department of Oruro is bounded on the N. by the department La Paz, E. by those of Cochabamba and Chuquisaca, S. by that of Potosi, and W. by Peru; area, 25,842 square miles. Pop. 117,000.

ORVIETO, a town of the Papal States, capital of a delegation of the same name, stands on a steep hill at the confluence of the Paglia and Chiana, 16 miles N.E. of Bolsena, and about 60 N.N.W. of Rome. It is a clean, well-built town, surrounded by walls; and contains several fine palaces. Besides the episcopal palace, the chief of these are,—the Gualterio, containing frescoes by Domenichino, Albano, and other artists; and the Palazzo Petrangeli, with a fine collection of paintings by Pietro Perugino. The cathedral, founded in 1290, is an Italian-Gothic edifice, with a front richly adorned with sculptures and mosaics, which is considered one of the finest in Italy. In the interior are many valuable paintings, and a large collection of sculptures. Orvieto contains several other churches, a Jesuits' college, and a town-hall; but the principal other object of interest is St Patrick's Well, excavated by order of Clement VII. in the tufo rock, about a mile from the town. Many Etruscan remains have been found here, this town having been built on the site of the ancient Herbanum. Some trade is carried on in cattle, corn, wine, and silk. Pop. 8000. The delegation of Orvieto has an area of 300 square miles. Pop. (1853) 29,047.

OSAKA, or OSACCA, a city of Japan, in the island of Niphon, near the head of a gulf of the same name, on the banks of the Yedogawa, which here divides itself into several branches. It is one of the five cities under the direct government of the Siogoon, or military emperor of Japan; and is defended by fortifications, and by a castle of great size at the north-eastern corner of the city. The middle channel of the river, though narrow, is navigable, and has a great depth; and many of the principal streets have navigable canals running through them. A great number of bridges, built of cedar wood, span these canals and the river; and many of them are large and elegantly adorned. The streets are regularly laid out at right angles to each other, and, with the exception of side causeways for foot passengers, they are quite unpaved, but clean and well kept. Along the banks of the river and canals there are several rows of coarsely-hewn freestone, arranged in the manner of steps, all throughout the town. The houses are in general built of wood, lime, and clay, and are two storeys high. Osaka contains a theatre and race-course; in which, as well as in other places of amusement, so many public exhibitions are carried on, that the city has been called by the Japanese the "universal theatre of pleasure and diversion." Many manufactures are pursued in the town and its vicinity; among which is that of *saki*, a kind of beer obtained from rice, which is exported to other parts of Japan. Some trade is carried on by junks between this place and Hakodadi. Osaka is said to be able to raise from among its own inhabitants an army of 80,000 men.

OSCHATZ, a town of Saxony, circle of Leipsic, on the Döllnitz, an affluent of the Elbe, 31 miles E.S.E. of Leipsic. It is surrounded by ancient fortifications, and contains many fine buildings. The town was in great part destroyed by a conflagration in 1842; and since that time there have been built a handsome new council-house, and an elegant church in the Gothic style, with two open spires, 276 feet in height. Besides another church, Oschatz contains courts of law and an hospital. Cloth, shoes, nets, tiles, and other articles are made. It was here that the treaty of peace was concluded between Frederic the Great and the Empress Maria Theresa which put an end to the Seven Years' War, in 1763. Pop. 5460.

OSCHOPHORIA, a festival celebrated by the Athenians, and which receives its name ἀπο του φερειν τας ὀσχας, *from carrying boughs hung with grapes*, which were called ὀσχαι. The original institution is mentioned by Plutarch, who ascribes it to Theseus, and says it was held in honour of Bacchus and Ariadne; but other writers maintain that it was celebrated in honour of Minerva and Bacchus. On the day of the festival, which probably occurred about the beginning of the Attic month Pyanepsion, two youths, whose parents were still alive, walked in procession, accompanied by a numerous retinue bearing vine branches hung with fresh grapes, from the temple of Bacchus to that of Minerva. Song and dance enlivened the march, and a sacrifice ensued.

The proceedings were concluded by a race, in which young men only whose parents were both alive had permission to engage. It was customary for them to run from the temple of Bacchus to that of Minerva, which was on the sea-shore. The reward of the conqueror was a cup called πενταπλοα, *five-fold*, because it contained a mixture of five different ingredients,—viz., wine, honey, cheese, meal, and oil.

OSERO, or LOSSINI, an island of Austria, in the circle of Trieste, Illyria, lies to the S.W. of the island of Cherso, with which it is connected by a bridge; area, 68 square miles. The inhabitants cultivate vines, olives, and fruit trees, rear sheep, and catch fish. The principal town is Lossini Piccolo, with the chief harbour in the island. It has distilleries, and a considerable trade in wine. Pop. 5179. The other towns are Lossini Grande (pop. 2389); and Osero (pop. 1157). Pop. of the island, 10,600.

OSIMO, a town of the Papal States, in the delegation of Ancona, stands in a rich and lively neighbourhood, on a hill on the Musone, 8 miles S.S.W. of Ancona. It is well built, and has a cathedral and other churches, an episcopal palace, and a town-hall, containing a collection of ancient statues and other remains found in the vicinity. This town occupies the site of the ancient Auximus, a place which became a Roman colony in 157 B.C.; after which period it was of considerable importance, especially in the wars of Belisarius, to whom it offered great resistance. Pop. 7000.

OSIRIS, one of the deities of the Egyptian Pantheon. (See EGYPT, sect. 1.)

OSNABURG (Germ. *Osnabrück*), a town of Hanover, capital of a province of the same name, stands in a valley on the Hase, a tributary of the Ems, 71 miles W. by S. of Hanover. It is surrounded by an old wall and ditch, and is entered by five gates. It is regularly laid out, and the most part of the houses are low and meanly built, but in the vicinity there are many handsome country houses. The cathedral is a fine edifice in the Romanesque style, built in the eleventh and beginning of the twelfth century. It has two square towers, and contains, among other curiosities, a richly-carved comb, said to have belonged to Charlemagne; relics of St Crispin, St Crispian, and other saints; and many valuable gold and silver crucifixes. The Lutheran churches of St Katherine and St Mary, and the Roman Catholic one of St John, are among the edifices most worthy of note in Osnaburg. The town-house, a fine castellated building, contains the hall in which, at the same time as in Münster, the treaty of Westphalia was concluded in 1648. The portraits of the ambassadors at this congress are still to be seen in the hall; and the town-house contains a collection of ancient drinking-vessels, arms, coins, and other antiquities. The town contains also several schools, hospitals, a workhouse, and a house of correction. Manufactures of coarse woollen stuffs, leather, linen, tobacco, and chemical products are carried on; and there is an active trade in these articles, in cattle, and agricultural produce. Linen is also made in large quantities in the vicinity, and sent hither to be stamped and sold. Osnaburg was a village of some importance as early as the time of Charlemagne. In 1082 it was first fortified; and at a later period it entered the Hanseatic League. It did not, however, attain the dignity of a free city. In 1626 a castle was built near the walls of Osnaburg by Bishop Francis William, in order to reduce to obedience the citizens, many of whom had embraced the Protestant faith; but this was destroyed by them in 1647. The province of Osnaburg has an area of 2407 square miles, and is bounded on the N. by the province of Aurich and the duchy of Oldenburg, E. and S. by Rhenish Prussia, and W. by Holland. Belonging to the plain of Northern Germany, the surface is almost entirely level, and the soil, being sandy and barren, yields but a scanty supply of corn. The principal productions are, cattle, hemp, and flax; while coarse linen and woollen fabrics are the chief among the manufactures. The country is famous for its hams, which are largely exported. The present province of Osnaburg nearly corresponds to the ancient bishopric of that name, which was the earliest see founded in Saxony by Charlemagne. Many of the people having become Protestants, it was decided by the treaty of Westphalia that the see should be held alternately by a Roman Catholic and by a Protestant bishop, the latter to be always chosen from the House of Brunswick-Luneburg. The last prince bishop of Osnaburg was Frederic, Duke of York, the second son of George III., who in 1803 made over the see, now only a temporal province, to Hanover. Osnaburg subsequently formed part of the kingdom of Westphalia and of the French empire; but was restored to Hanover after the fall of Napoleon. Pop. of the province (1855), 259,821; of the town (1852), 13,718. Of the inhabitants of the province at the above date, there were 88,814 Lutherans, 25,951 of the Reformed Church, and 144,321 Roman Catholics.

OSORIO, GERONYMO, a learned ecclesiastic, called from the purity and elegance of his Latinity "the Cicero of Portugal," was sprung from a noble family, and was born at Lisbon in 1506. He studied languages at Salamanca, philosophy at Paris, and theology at Bologna. Having secured the patronage of royalty on his return to Portugal, he was raised through successive dignities to the bishopric of Sylves. At the request of the notorious Cardinal Henry, Osorio undertook his *De Rebus Emmanuelis Regis Lusitaniæ, virtute et auspicio gestis, libri XII.* This work appeared at Lisbon in 1571, and *Os Lusiadas* of Camoens in 1572. Thus, while the sublime daring of Vasco de Gama was moving the elegant pen of the good bishop, the same grand exploits were melting into noblest music the heart of the much-suffering poet. Yet the historian was admitted to the friendship of kings, while the poet wandered a beggar through the streets of Lisbon. Both lived to witness the calamitous disasters of King Sebastian's African expedition; but patriotism was too strong in each to outlive it long. Osorio died in 1580, a year after Camoens. After his History, the most noted book of Osorio is the *De Gloria, libri V.*, written with such singular elevation of spirit and felicity of diction that D'Alembert asserted it to be a production of Cicero's palmed off upon the world by the learned bishop as his own. A curious admonition to Queen Elizabeth, exhorting her to return to the bosom of the Church of Rome, is also to be found among the writings of Osorio. In addition to paraphrases and commentaries on various books of Scripture, he also wrote *De Nobilitate Civili et de Nobilitate Christiana* (1552); *De Regis Institutione* (1572); *De Justitia Cœlesti* (1580); *De Sapientia*, &c. (See Jöcher's *Lexicon*.) His entire works were collected and published at Rome, in 4 vols. 4to, with a Life of the author, in 1592, by his nephew of the same name. The more popular writings of Osorio have been translated into English, French, and Portuguese.

OSSA, a lofty mountain in Thessaly, separated by the vale of Tempe from Mount Olympus, from which the ancients conjectured it had been divided by an earthquake. It is conical in form, with a single summit, rising, according to Dodwell, to a height of 5000 feet. Ossa is lower than Olympus and Pelion, the two mountains with which its name is associated in the fabulous wars of the giants and the gods. Its modern name is *Kissovo*.

OSSIAN, or OISIN, a traditionary poet of great celebrity, whose compositions in the Celtic language were for centuries popularly recited in Ireland and the Highlands of Scotland. It was only at a comparatively recent period that the literary world became aware of the existence, or at least the fame, of this Celtic Homer, and by many he is still regarded as a mythical personage.

In the year 1759 John Home, the Scottish dramatic poet, passed part of the summer at the pleasant little watering-place of Moffat, in the south of Scotland; and in his walks, or at the bowling-green there, he became acquainted with another visitor at the spa—James Macpherson, a young intelligent Highlander, then in his twenty-first year. Having completed his education at the university of Aberdeen, and taught a school for a short time at his native place—Ruthven in Badenoch,—Macpherson was engaged as tutor to Mr Graham, younger of Balgowan (afterwards Lord Lynedoch), who was then residing at the house of his relative, Lord Hopetoun. Always enthusiastic about poetry and the Highlands, Mr Home made inquiries of Macpherson relative to the reported traditionary poems of the old Celtic bards, of which he had heard some account from his friend Adam Ferguson, and a specimen of which had appeared in the *Scots Magazine* for 1756. Macpherson confirmed the statements as to the existence of a large amount of ancient Celtic poetry in the Highlands which had been preserved by oral transmission from one generation to another. He produced translations of two pieces, and Home was much struck with the wild beauty and originality of the poetry. On his return to Edinburgh he submitted the translations to Dr Hugh Blair and other friends, by all of whom they were greatly admired. Copies also found their way to England, and Gray the poet was, he says, "so *extasié* with their infinite beauty," that he wrote to Scotland making a thousand inquiries. Blair sought out the translator, and urged him to proceed in rendering versions of all the poems in his possession. Macpherson was reluctant to undertake the task, but at length he complied with the request; and Dr Blair having obtained a sufficient number of pieces to form a small volume, published them in 1760, under the title of *Fragments of Ancient Poetry collected in the Highlands of Scotland, and translated from the Gaelic or Erse language.* To this work Blair prefixed a preface embodying the information communicated to him by Macpherson, and stating that many more remains of ancient genius, and especially one work of considerable length, "deserving to be styled an heroic poem," relating the expulsion of the Danes by Fingal, might still be found in the Highlands. A subscription was entered into to enable Macpherson to make a tour for the purpose of collecting these precious remains. Lord Elibank, Dr Robertson, John Home, Adam Ferguson, and other persons of rank and taste in Edinburgh, subscribed sums; and Horace Walpole tells us he was also a contributor.

Under the patronage of these eminent individuals, Macpherson performed his literary tour in 1760, transmitting from time to time accounts of his progress, and of the various poems which, as he said, he had succeeded in collecting. The districts through which he travelled were chiefly the north-western parts of Inverness-shire, the Isle of Skye, and some of the adjoining islands; places which, from their remoteness, and the state of manners that then existed in them, were thought the most likely to afford, in a pure and genuine form, those traditionary tales and poems in the recital of which the Highlanders were represented as taking so much delight. On his return from the north, Macpherson passed some time with an early acquaintance of his own, Mr Gallie, then a missionary in Badenoch, and availed himself of the assistance of this gentleman, as well as that of Mr Macpherson of Strathmashie, in collating the different copies of the poems which he had collected, in translating difficult passages, and in determining the meaning of obsolete words. He then proceeded to Edinburgh, where he communicated to his patrons the result of his expedition; and in 1762 published *Fingal*, an epic poem in six books, with some other detached pieces of a similar kind. In an advertisement prefixed to *Fingal*, he states, that "some men of genius had advised him to print the originals by subscription, rather than deposit them in a public library;" and, in the preliminary dissertation he says, that "his translation is literal, and that, as he claims no merit on account of his version, he wishes that the imperfect semblance which he draws may not prejudice the world against an original which contains what is beautiful in simplicity, or grand in the sublime." In the year 1765, he published another epic poem, entitled *Temora*, to the seventh book of which he annexed the original Gaelic; but of all the rest he published only translations.

Macpherson had now not only enlarged his plan, but had altered the chronology of the poems. In the preface to the *Fragments* he had instructed Blair to represent them as probably coeval with the infancy of Christianity in Scotland: in one piece a Culdee or monk held a dialogue with Ossian, and this seemed to fix the date as not earlier than the sixth century. In his epic of *Fingal*, however, Macpherson boldly placed his Celtic bard in the end of the second or the beginning of the third century. Several incidents in the poem pointed out this era, particularly the engagement of Fingal (the son of Ossian) with *Caracul*, described by the translator as the same with the son of Severus, the *Caracalla* of Roman history. Fingal, who commanded the Caledonians at that memorable juncture, is said to have eluded the power of Severus, and gained a signal victory on the banks of the Carron, in which Caracul fled from his arms "along the fields of his pride." Here, then, was a startling fact—a text for controversy: could the remote Highlands be in such a state of civilization and refinement at the time of Severus? The parallel, as Gibbon said, "was little to the advantage of the Romans, if we compare the unrelenting revenge of Severus with the generous clemency of Fingal; the timid and brutal cruelty of Caracalla, with the bravery, the tenderness, the elegant genius of Ossian; or the mercenary chiefs who, from motives of fear or interest, served under the imperial standard, with the free-born warriors who started to arms at the voice of the king of Morven?" This eloquent eulogium would be well merited if we could "indulge the pleasing supposition that Fingal fought and Ossian sung" in the reign of Severus. But Gibbon himself offers one objection which destroys the hypothesis. The name of Caracalla was a nickname given to the son of Severus in derision. His real name was Bassianus, but he adopted the honoured name of Antoninus. In the Caledonian war he was known only by the appellation of Antoninus; and it was in the highest degree improbable that a Highland bard, even gifted with the second sight, should describe him by a nickname invented four years afterwards, scarcely used by the Romans till the death of that emperor, and seldom employed by the most ancient historians. This false step in his chronology strikes at the root of the translator's claim of great antiquity. David Hume took a more popular objection, which Johnson afterwards urged with great force. Is it possible that above 20,000 verses, along with numberless historical facts, could have been preserved by memory and tradition during fifty generations by the most turbulent and unsettled of all the European nations? No one, we think, will answer unreservedly in the affirmative. But Macpherson had the aid of at least *some* ancient manuscripts; and we must remember that it was the duty of the Celtic *senachies* or bards to recite poetry of this description, while it was the favourite amusement of the people during the long winter nights to listen to such recitations. National vanity, old associations, a love of song, and the habits and circumstances of the Highland people, all combined to perpetuate this traditional literature. It is undoubted that the tradition of a great hero or chief called Fion, Fion na Gael, or, as it is modernized, *Fingal*, existed in Ireland and in the Highlands, and that certain ballads

containing the exploits of this chief and his brother warriors were the favourite lore of the peasantry. *Ossian dall*, or blind Ossian, was as familiar, we are informed, as *strong Samson* or *wise Solomon*. The ancient Scottish poets, Barbour, Dunbar, and Gavin Douglas, had alluded to the exploits of Fingal; and in 1567 Bishop Carswell printed Knox's Forms of Prayer and Catechism translated into Gaelic—the first book printed in that language—to counteract, he says, "the lying worldly histories concerning warriors and champions and Fingal, the son of Combal, with his heroes." Abundant evidence then existed as to the popular belief in those ancient Celtic chiefs, the actors in Macpherson's epic poem; and the next point was to ascertain the precise nature of the Ossianic poetry which the Highlanders used to repeat and admire, and which Macpherson had professed to translate. The translator himself would render no assistance in solving the difficulty. At first he represented his translation as literal; and in his dissertation, published in 1762, he says, that "the translator, as he claims no merit from his version, wishes that the imperfect semblance which he draws may not prejudice the world against an original which contains what is beautiful in simplicity, or grand in the sublime." But, afterwards, when the success of his translation had been ascertained, he began to hold very different language; and, notwithstanding the strong and pointed assertions of their originality which he had advanced in his prefaces and dissertations prefixed to the earlier editions of these poems, he allowed expressions to escape him which unequivocally indicated an intention of appropriating the *authorship* to himself. In one passage he says that those who have doubted his veracity have paid a compliment to his genius, and that *even* were the allegation true, his self-denial might have atoned for his fault. "I can assure my antagonists," he adds, "*that I should not translate what I could not imitate*;" and again, in a similar vein, he says that "the translator who cannot *equal* his original is incapable of expressing its beauties." As his confidence increased, he became still more explicit, and in one of his prefaces we meet with the following passage:—"Without increasing his genius, the author may have improved his language in the eleven years that the poems have been before the public. Errors in diction may have been committed at twenty-four which the experience of a riper age may remove, and *some exuberances of imagery may be restrained with advantage* by a degree of judgment acquired in the progress of time. *In a convenient indifference to literary fame, the* AUTHOR *hears praise without being elevated, and ribaldry without being depressed.* The writer's first intention was to have published in verse; and as *the making of poetry* may be learned by industry, he had served his apprenticeship, though in secret, to the Muses." His service had been more secret than he at one time desired, for in 1758 Macpherson had published a poem, *The Highlander*, which was utterly worthless, and instantly sunk into oblivion. The imagery and description, however, have something of the Ossianic vein, though at times reduced to the lowest point of tenuity, or swelling into outrageous fustian. Some still earlier pieces by Macpherson, published in the *Scots Magazine*, are feeble paraphrases of passages in Pope and other poets. The controversy as to the genuineness of the Ossianic poems was carried on with much keenness and asperity. Johnson, in his celebrated *Journey to the Western Islands* (1774), had declared his conviction that the poems never existed in any other form than that in which they were published by Macpherson; and that there could not be recovered in the whole Erse language 500 lines of which there was any evidence to prove them a hundred years old! Macpherson replied by sending Johnson a challenge; a proceeding ludicrously absurd and in every sense impertinent, and which Johnson properly met by that memorable short letter of defiance in which he said he should never "be deterred from detecting what he thought a cheat by the menaces of a ruffian;" and that "what he had heard of the *morals* of his opponent inclined him to pay regard, not to what he should say, but to what he should prove." This was sufficient for Macpherson; but Dr Blair felt that his credit was at stake. He had written a dissertation to prove the genuineness of the translated poems, and procured testimonies from a number of clergymen and gentlemen in the Highlands in support of his theory. Still no conclusive ancient document or direct incontestable evidence was brought forward, and the case was rendered still more desperate by a dissertation from Mr Malcom Laing, who reviewed the whole subject—the Roman history of Britain, the middle ages, tradition, the customs and manners of the times, the real origin of the poems, imitations of the ancient and modern poets, the pretended originals, and Macpherson's indirect avowal of the whole imposture—pronouncing emphatically against the translator on all these various heads. This dissertation by Laing is an ingenious and elaborate display of criticism; but the Gothic predilection of the acute Orcadian had carried him too far, and subsequent researches have disproved some of his inferences and allegations. To settle the question, the Highland Society appointed a committee to inquire first, what poetry, of what kind, and of what degree of excellence, existed anciently in the Highlands, and was generally known by the denomination of *Ossianic*, from the universal belief that its author was Ossian, the son of Fingal; and secondly, how far that collection of such poetry published by Macpherson was genuine.

In answer to the first of these questions, the committee state with confidence an opinion "that such poetry did exist; that it was common, general, and in great abundance; that it was of a most impressive and striking sort, in a high degree eloquent, tender, and sublime." The second question, however, the committee found "much more difficult to answer decisively." They were possessed of no documents to show how much of his collection Mr Macpherson had obtained in the form in which he gave it to the world. The poems and fragments of poems they had been able to procure contained often the substance, and sometimes almost the literal expression of *passages* given by Mr Macpherson in the poems of which he published translations. "But the committee has not been able to obtain *any one poem the same in title and tenor* with the poems published by him. It is inclined to believe that *he was in use to supply chasms, and to give connection by inserting passages which he did not find, and to add what he conceived to be dignity and delicacy to the original, by striking out passages, by softening incidents, by refining the language*; in short, by *changing* what he considered as too simple or too rude for a modern ear, and *elevating* what in his opinion was below the standard of good poetry. To what degree, however, he exercised these *liberties*, it is impossible for the committee to determine." In fact, Macpherson had founded his epic poems on the ancient traditionary fragments, as Shakspeare had founded his immortal dramas on the rude though popular basis of old plays, novels, and historical chronicles. Parts of *Fingal* are undoubtedly genuine, and have been written down from the recitation of parties who never read the *Ossian* of Macpherson. The Address to the Sun (which Laing attacked as an imitation of Milton) is also a genuine fragment, and other beautiful passages scattered throughout the poems have been traced to the original traditionary sources. Of the MSS. used by Macpherson one only has descended to us. This is a large collection of Celtic poems composed at various periods, which appears to have belonged to the Rev. James Macgregor, Dean of Lismore, partly written in 1512, and partly in 1527. The volume is now in the Advocates' Library,

 Edinburgh, and has lately been carefully examined by a competent Celtic scholar, the Rev. Thomas M'Lauchlan. Historical incidents and passages in Macpherson's *Ossian* are found in this MS.—as the death of Oscar, the story of Faineasolis (the Maid of Craca in *Fingal*), and the story of Cuchullin, and his son Conlaoch, which was well known both in Ireland and the Highlands. The names of Fingal, Gaul the son of Morni, Oscar the son of Ossian, Garve the son of Starno, the Danes, Cuchullin &c., also abound; but there is one peculiarity in the Lismore MS. on which Macpherson was silent—it agrees with the Irish MSS. in the introduction of St Patrick, and in relating dialogues on Christianity between the Saint and Ossian, thus fixing the era of Ossian as that of St Patrick, and indicating that his country was not Scotland but Ireland.[1] This point does not seem to us of great importance. The unfaithfulness of Macpherson being admitted, it is easy to account for the Celtic poems being found equally popular in both Ireland and the Highlands. The people were of the same race, spoke the same language, and had constant intercommunication. The bards passed from one country to the other; the traditional poetry and legends formed a common inheritance, which would gradually undergo adaptation to the different localities and events. Some fragments may be of great antiquity, describing the prowess of the Fingalians (whose names at least existed at a very early period), and it is in favour of this supposition that the Celtic language seems to have undergone no radical change. The Irish antiquaries have of late diligently explored the ample field of their early literature, and their publications throw much light on the history of the Celtic race in these islands.

The literary merits of Macpherson's *Ossian*, extravagantly overrated at first, have experienced the usual reaction in such cases, of being unduly depreciated and contemned. If the fragments had not possessed poetical imagination and real genius, they would never have excited the warm admiration of Gray, whose taste and sensibility were so exquisite. As pictures of actual society and manners, the poems are of course spurious and deceptive; no one will, in this respect, attempt their defence. But Mr Wordsworth has attacked them on the score of their alleged false imagery and want of descriptive fidelity. "In nature," he says, "everything is distinct, yet nothing defined into absolute independent singleness. In Macpherson's work it is exactly the reverse; everything (that is not stolen) is in this manner defined, isolated, dislocated, yet nothing distinct." This may partly arise from the style of the translator, consisting as it does of broken paragraphs, unconnected and deficient in cadence. The genuine fragments, however, show that such a style is substantially true to the original. The Celtic bards had a peculiar diction, and dealt only in brief strokes of description. They sketched the broad outlines of the mountain landscape, the leading objects of nature or of passion, and attempted no delineation of the finer features, or of the atmospheric phenomena so characteristic and attractive in mountainous districts. With them "autumn is dark on the mountains, gray mists rest on the hills, dark rolls the river through the narrow plain," and "the musing hunter alone stalks over the heath." The enumeration is simple but suggestive; and in the more ambitious passages—in the apostrophes to the setting sun, the moon, or tempest—in pictures of solitary desolation, and in the melancholy superstition which evokes the ghosts of the departed Finian chiefs—we have bursts of true pathos and elevated imagination. The chief drawback to this ancient poetry is the constant repetition of the same ideas, sentiments, and imagery, which, however natural in an early stage of literature and of society, soon palls upon all but very young and romantic readers. No poetry is read with greater avidity in youth, or is so soon and so completely abandoned in after years.

It is worthy of remark that Macpherson's *Ossian*, in a French version, was the favourite reading of the great Napoleon. It stimulated his imagination, and coloured his despatches and addresses to the army. When he told his soldiers in view of the Pyramids, that "the shades of forty centuries looked down upon them," we recognise the vivifying power of genius, but genius lighted at the torch of *Ossian*. The poems made the fortune of their translator. Their first effect was enriching him to the amount of nearly L.2000, and obtaining for him the patronage of Lord Bute. Once brought into public notice, Macpherson's talents and energy soon secured preferment. He obtained a colonial appointment and pension; became, on his return to England, engaged in public affairs; and was an active supporter of government. His political pamphlets and letters at the period of the American war were highly popular, though perishing with the topics of the day that had called them forth. He attempted history, but without success proportioned to his labour or party zeal; and he egregiously failed in a translation of Homer in the style of Ossian. "Few people," as Scott said, "cared to see their old Grecian friend disguised in a tartan plaid and philabeg." In public life Macpherson was now conspicuous, and he obtained the lucrative appointment of secretary to the nabob of Arcot, with a seat in the House of Commons. Finally he retired to his native district, purchased a considerable estate (the old patrimony of the Mackintoshes of Borlum), and, building a splendid mansion on his property, died there at the age of fifty-six, his death occurring in the same year that witnessed the decease of Burns. How different the fate of the two Scottish poets! Macpherson was a man of undoubted genius, but of defective taste and lax principle. His Celtic enthusiasm was the fount of his highest inspiration, and the reign of Ossian may be said to have died with him. The accomplished scholars of Ireland have resuscitated much more of the ancient minstrelsy, but it is immeasurably inferior to the Macpherson fabric; and though interesting to a few as illustrations of a past state of manners and feeling, it has no pretensions to be regarded as adding to the value of our poetical literature. (R. C—S.)

 OSSOLI, Sarah Margaret Fuller, *Marchioness*, the eldest child of Timothy Fuller and Margaret Crane, was born at Cambridge Port, Massachusetts, U. S., on the 23d of May 1810. Her father, who was a lawyer there, took charge himself of her education, but with an imprudence which afterwards cost her much suffering, began too early and exacted too much for the health of his child. She was of nervous and excitable temperament, and of a precocious activity of mind, which required a different regimen from the stimulants of school tasks. She was able to read Latin at six years of age, picked up some knowledge of French, and eagerly devoured all the English books within her reach. Headaches, somnambulism, and spectral illusions were the results of this injudicious excitement of the brain, and, attributing her feeble health to her solitude, her father sent her to a ladies' school at Groton. Afterwards she received instruction in Greek and mathematics from Dr Park of Boston. In 1832 she studied German, and in three months could enjoy the masterpieces of German

[1] The Rev. T. M'Lauchlan. *Archæological Journal*, 1857. Mr M'Lauchlan considers these passages as interpolations of the Irish bardic school, in which so many of the Scottish bards were trained. (See also *Transactions of the Ossianic Society*, Dublin, 1855.) The Irish poems represent Ossian as reciting his strains to St Patrick "in the latter days, when, the glory of the Finians having departed for ever, he alone of them survived, infirm, blind, and dependent upon the bounty of the first Christian missionaries to Ireland." The discipline of Christianity sat most uneasily upon the old pagan bard, who sighed for the harp and feast, the battle and the chase. In the number of the *Archæological Journal* above referred to is an able paper on the Ossianic controversy by Lord Neaves, a Scottish judge.

literature. She was at once brought under the fascination of Goethe, whose doctrine of self-culture the highest aim took possession of her whole soul. Her reading, though diligent and extensive, does not seem to have been systematic, and she never subjected herself to the wholesome discipline of science. She did not lack for her self-culture whatever advantages the most intellectual society of Boston could confer. By her remarkable powers of conversation, and her noble and sympathetic nature, she attracted round her, and personally attached, a very great number of young and ardent friends of both sexes. It is not to be questioned, at the same time, that she was enormously conceited, dogmatic, and exaggerated in thought and feeling, and she was only spoiled by the intense adoration of her coterie. She had a cherished purpose of visiting Europe, and hoped to do so in the society of Miss Martineau, whom she met in 1835; but the death of her father, in October of the same year, laid new responsibilities on her, from which she did not shrink. In the autumn of 1836 she went to Boston to teach Latin and French in a public school, and also formed classes for young ladies in French, German, and Italian. Her success and ability procured her in 1837 the situation of "lady superior" in the Green Street School, Providence, Rhode Island, which she occupied till 1839. After various migrations, she settled with her mother and family in Boston in 1841. In 1839 she had published a translation of Eckermann's *Conversations with Goethe*, and this was followed in 1841 by a translation of the letters of Gunderode and of Bettine. Her intended Life of Goethe was never completed; but she found continuous literary occupation in the *Dial*, a publication established by the so-called Transcendentalists, which she edited for two years from its commencement in 1840, and in which she published three noticeable papers—a criticism on Goethe; "The Great Lawsuit," afterwards expanded into *Woman in the Nineteenth Century*, and "A Summer on the Lakes," also enlarged into a book in 1844. A characteristic undertaking of hers in Boston was her conversation classes, re-unions once a week, in which many of the most cultivated ladies took part, and where such subjects as Greek mythology, the fine arts, the position of women, dæmonology, and the ideal, were discussed, Miss Fuller presiding. What has been reported of the debates of these *ecclesiazusæ* gives no high idea of their practical utility; they have rather a peculiar comic aspect, and bear a striking resemblance to the immortal *conversazione* at which Mr Martin Chuzzlewit was present. On the other hand, her writings, in which she felt herself comparatively cramped, display much sense and vigour, some originality, and a growing felicity of image and expression. In 1844 she went to New York as literary contributor to the *Tribune*, and while there, resided in the house of the editor, Mr Horace Greeley. Her articles were collected and published in two volumes in 1846. That year she made her visit to Europe, passing some time in England and France, and finally fixing her abode in Italy. She had always been attached to that country and its literature, had made the acquaintance of Mazzini in England, and was warmly interested in the progress of liberalism. In December 1847 she was married to the Marquis Giovanni Angelo Ossoli, but their union was kept secret to save his fortune till the establishment of the hoped-for reforms might render an avowal safe. She had a son in September 1848. She was in Rome during the siege in 1848–49, and superintended one of the two hospitals, while her husband fought on the walls, and her child was left in charge of a nurse in the village of Rieti. In September 1849 they retired to Florence, where they lived in painfully narrow circumstances. She occupied her leisure with the completion of a history of the recent events which she had all along been preparing. She determined to return to America with her family, and to resume her literary career with the publication of her work, on which she founded high expectations. They set sail from Leghorn, 17th May 1850, in the barque Elizabeth; and the voyage was prosperous till they reached the coast of New Jersey, when, in a dreadful gale, the ship struck on Fire Island beach, 16th July. Some of the crew and passengers saved themselves, but the Ossolis perished. Margaret Fuller was a woman of very extraordinary endowments, and her loss was deeply regretted as a calamity to American literature and progress. Memoirs of her, compiled by her friends, W. H. Clarke, R. W. Emerson, and W. E. Channing, were published in 1852.

OSTADE, ADRIAN VAN, an eminent painter of the Dutch school, was born at Lubeck in 1610, and studied at Haarlem, in the school of Frank Hals. His genius was early developed, and soon struck out a path for itself in the province of art. He chose for his principal subjects the gambling pastimes, the uproarious merry-makings, the sottish drinking-bouts, or the drunken frays of a country ale-house. He was also fond of painting an alchymist's laboratory, the office of a country lawyer, and the interior of a peasant's cottage. All these scenes, so mean and humble in themselves, were invested with the charms of consummate artistic skill. The characters were well distinguished by different physiognomies, the accessories were successfully arranged, the colouring was warm and harmonious, and the chiaroscuro was unrivalled. Accordingly, the artist enjoyed an extensive reputation and patronage, from the beginning of his career at Haarlem till his death at Amsterdam in 1685. His numerous works have also continued to rise in the public estimation ever since his demise. Specimens abound in several of the English collections, in the galleries at Amsterdam, the Hague, Dresden, Munich, and Vienna, in the Hermitage at St Petersburg, and the Louvre at Paris.

OSTADE, *Isaac van*, the brother of the preceding, was born at Lubeck in 1617. Although a pupil, and at first an imitator of Adrian, he soon adopted a manner of his own. A frozen canal covered with sledges and skaters, and the yard of a country inn bustling with huntsmen, waggoners, and travellers, were his favourite subjects. He painted these with a knowledge of the principles of art which would probably have gained for him a reputation equal to that of his brother, had not death prematurely closed his career at the age of thirty-seven.

OSTASHKOV, a town of European Russia, in the government of Tver, on a small promontory in Lake Seliger, 110 miles W. of the town of Tver. The houses are for the most part built of wood; but there is a large bazaar, containing the shops, which are all of brick. There are several churches, courts of justice, a nunnery, school, and several hospitals. Malt, leather, and tallow are made, as well as boats for the Volga. Some trade is carried on in corn, salt, meat, leather, tallow, timber, &c. Pop. (1849) 8254.

OSTEND (Fr. *Ostende*), a fortified seaport-town of Belgium, province of West Flanders, stands on a low piece of ground, nearly surrounded with water, 12 miles W. of Bruges, and 67 N.W. of Brussels. The town is clean, the streets regularly laid out, and the houses, which are neatly built, present a cheerful appearance, from being painted of various colours. The place is, however, generally considered dull and uninteresting by English travellers; and it has few public buildings of any note. The town-hall, though large and handsome, is a plain structure; and of the several churches, hospital, barracks, arsenal, and prison, none are in any way remarkable. There are several squares and public walks; the most agreeable of the latter, and at the same time the most noteworthy object in Ostend, being what is called the Digue, a breakwater 40 feet high, faced with stone, which extends for half a mile

between the sea and the fortifications. This is much frequented as a promenade, and commands an extensive view over a flat sandy expanse, entirely destitute of trees. The harbour, though difficult of access, on account of a sandbar at the mouth, is large, and forms the termination of a magnificent series of canals which intersect the country in a sort of network. Vessels of 300 tons may sail by this means as far as Bruges. The sluices by which the canal communicates with the harbour are remarkably well constructed. Ostend is much frequented by the Belgians as a watering-place, and the king and queen frequently visit it in the summer. There are numerous bathing-machines, and a good bathing-house. The manufactures are not of any importance, comprising linen, sail-cloth, lace, hats, tobacco, and other articles. The cod and herring fishery gives employment to many of the inhabitants, and oysters, brought over from the English coast, are fattened here in salt reservoirs, and sent to Paris under the name of Ostend oysters. The trade of Ostend is very considerable, consisting in the exportation of rural produce, leather, tallow, salt, &c., and the importation of colonial produce, wool, wines, manufactured goods from England, and other articles. Its prosperity has been much increased by the introduction of railways, by which it is connected with the chief places in Belgium, France, and Germany. The fortifications of the town are very strong, as it is one of the fortresses that defend the French frontier of Belgium. They consist of ramparts, a broad ditch, and a citadel, and the town is entered by four gates. In the ninth century a small village existed on this site, which 200 years after had become a busy seaport; but this town was destroyed by the sea in 1334. The present town was afterwards built, and gradually rose from a small fishing village to its present importance. It was walled in 1445, and regularly fortified by the Prince of Orange in 1583. During the war of the Dutch against Spain, Ostend sustained a memorable siege for more than three years (1601–1604). So tremendous was the bombardment that the noise of the Spanish artillery is said to have been occasionally heard at London. At last, after a loss of 50,000 men on the part of the garrison, and 80,000 on that of the Spaniards, the town surrendered on honourable terms; and the Spanish general Spinola was put in possession of Ostend, now reduced to heaps of ruins. It has since sustained several sieges, successful and unsuccessful; and in 1826 was partially destroyed by the blowing up of a magazine. Pop. 14,665.

OSTEOLOGY. See ANATOMY.

OSTERODE, a town of Hanover, in the principality of Grubenhagen, and circle of Hildesheim, stands on the Söse, at the foot of the Hartz Mountains, 10 miles S.E. of Eimbeck. It is surrounded by walls, and contains several churches, a town-hall, an infirmary, and Latin school. The castle, now used as a granary, is a large stone edifice. Osterode is the chief manufacturing town in Hanover, producing linen, woollen, and cotton stuffs; nails, wooden articles, shot, needles, &c. There are also breweries, distilleries, and tanneries. Pop. (1852) 5504.

OSTERVALD, JEAN FRÉDÉRIC, a distinguished Protestant divine, was born at Neufchâtel on the 25th November 1663. He gave early marks of great intellectual precocity, and reaped laurels in philosophy both at Zurich and Saumur while yet a mere lad. After obtaining his master's degree at the latter place, he studied theology successively at Orleans, Paris, and Geneva. He was afterwards appointed pastor of the Reformed church of his native town, a position which he continued to adorn by his learning and zeal during a long life. In the first years of his ministry the political condition of Neufchâtel was critical in the extreme, and the amicable settlement of its affairs which afterwards ensued was in a great measure owing to the sagacity, energy, and moderation of Ostervald. A close friendship was soon formed between the pastor of Neufchâtel, J. A. Turretin of Geneva, and S. Werenfels of Bâle. These eminent men went by the name of "the triumvirate of Swiss divines," and did much to revive the cause of true religion in Switzerland. In addition to the active and laborious duties of a pastor and preacher, Ostervald found leisure to extend his reputation as a man of learning and piety in various able and popular works. He wrote a *Traité des Sources de la Corruption*, Amst. et Neuf. 1699; *Catéchisme, ou Instruction dans la Religion Chrétienne*, Genève, 1702; *Traité contre l'Impureté*, Amst., 1707; *Arguments et Reflexions sur l'Ecriture Sainte*, Neuf. 1720; *Traduction de la Bible*, Neuf. 1744; *Sermons sur Divers Textes de l'Ecriture Sainte*, Genève, 1722–24. Three other works bearing his name were published from notes of his lectures, but without the author's consent. These were *Ethica Christiana*, London, 1727; *Theologiæ Compendium*, Bâle, 1739; and *Traité de l'Exercise du Minitère Sacré*, Amst. 1737. His works attained to a great popularity with the French Protestants; and he was long spoken of among them as "*le Grand Ostervald*." His writings were likewise translated into English and German; and "Ostervald's Bible" was long well known and much prized in this country. Ostervald died on the 14th of April 1747, in his eighty-fourth year. (See his Life by David Durand, London, 1778.)

OSTIA, a seaport-town of Latium, was, as its name implies, at the mouth of the Tiber, at the distance of 16 miles from Rome by the Via Ostiensis. It was founded by Ancus Marcius, and originally derived its importance from supplying salt to the neighbouring district. Becoming in course of time the port of Rome, it began to flourish simultaneously and proportionally with that city. In the second Punic war, merchant vessels with grain from Sicily and Sardinia, and ships of war for the protection of the coast, were wont to throng its harbour. It was also about the same time the seat of a quæstor, who was called *Quæstor Ostiensis*, and whose task was to provide Rome with corn. But all the while the mud brought down by the Tiber was filling up the harbour, and rendering it incapable of receiving large vessels. That another port should be made for the capital of Italy was accordingly seen to be necessary. On the shore, about 2 miles north from Ostia, a new basin, called the Portus Augusti, and communicating with the Tiber by means of an artifical canal, was dug by the Emperor Claudius; an inner basin, called Portus Trajani, was added by Trajan; and this double harbour came to be called Portus (*Porto*), and gradually drew away all the traffic from Ostia. That ancient town had thus reached its acme of prosperity. Although handsome public edifices were reared by successive emperors, it dwindled down by degrees, until in the middle ages it fell completely into ruins. These ruins have been left by the constantly advancing shore about 3 miles from the mouth of the Tiber. About half a mile further up the river is the modern Ostia, an insignificant village.

OSTRACISM (ὀστρακισμός, from ὄστρακον, a *tile* or *shell*), a peculiar institution employed by the Athenian people for banishing from the state for a limited period such persons as were deemed dangerous to the republic either from their wealth or personal influence. (Aristotle, *Polit.* iii. 8.) It is said to have originated with Cleisthenes after the expulsion of the Pisistratidæ, and differed from the ordinary banishment (φυγή) in allowing the proscribed to enjoy their estates in a fixed residence, and to return after a term of ten years, subsequently reduced to five. (See EXILE.) Ostracism involved no dishonour, and was so far from casting any taint upon the reputation of a citizen that it was generally regarded as in reality a public compliment paid to conspicuous merit. That some other mode of acknowledging worth would have been preferred by public

men is likely enough; yet in the opinion of Mr Grote, who is ingenious in his defence of the policy of ostracism, this institution was necessary as a means of awakening in the multitude, and especially in ambitious men, "that rare and difficult sentiment which we may term a constitutional morality." (*History of Greece*, vol. iv. p. 205.) It was a general principle of the Athenian constitution that "no law shall be made against any single citizen without the same being made against all Athenian citizens, unless it shall so seem good to 6000 citizens voting secretly;" and under this general provision ostracism was a particular case. Before the vote of ostracism could be taken, the senate and the public assembly had to meet in the sixth prytany of the year, and deliberate upon the propriety of exercising the measure at that particular time. If their decision was in the affirmative, a day was named when the Athenian people assembled in the market-place according to their ten tribes. The agora was railed round, with an entrance left for each tribe, through which the citizens passed, and cast each a shell or potsherd (ὄστρακον), containing the name of the individual designed to be banished, into a cask or vessel which stood in the centre to receive the suffrages. At the close of the day the votes were summed up under the superintendence of the nine archons and the senate; and if any one person was found to have 6000 votes against him, that person was banished; but if the hostile votes did not amount to that number the proceeding ended in nothing. When one happened to be ostracized, he required to depart from Attica in ten days for a period of ten years; this was the sum of the penalty. With respect to the number of votes necessary to banish a citizen, Plutarch alleges that it was not necessary that 6000 should be given against one individual, but simply that the sum total should not be under that number. (*Aristeid.*, c. 7.) This view is likewise supported by Böckh and Wachsmuth; but Grote, following Philochorus, Pollux, the scholiast on Aristophanes, Platner, and Heumann, maintains that the former opinion is the only one consistent with the design of Cleisthenes in instituting ostracism for the preservation of the nascent democracy.

In order the more thoroughly to render ostracism effective in protecting the constitution, and the better to hinder it from being diverted to any other purpose, whether of private revenge or of the intrigue of faction, Cleisthenes ordained that if the process of ostracizing were opened at all, every citizen of Athens, without a single exception, should be exposed to its sentence, and run the risk of its penalty. Thus the tutelary influence of this *privilegium*, as the Romans would have called it, not merely operated when it was actually employed, but the knowledge of its existence is supposed to have exercised a restraining effect upon public leaders or men of ambitious temper. "Care was taken," says Grote, "to divest the ostracism of all painful consequence except what was inseparable from exile; and this is not one of the least proofs of the wisdom with which it was devised. Most certainly it never deprived the public of candidates for political influence; and when we consider the small amount of individual evil which it inflicted,—evil, too, diminished, in the cases of Kimon and Aristeidês, by a reactionary sentiment which augmented their subsequent popularity after their return,—two remarks will be quite sufficient to offer in the way of justification. First, it completely produced its intended effect; for the democracy grew up from infancy to manhood without a single attempt to overthrow it by force; a result upon which no reflecting contemporary of Cleisthenes could have ventured to calculate. Next, through such tranquil working of the democratical forms, a constitutional morality, quite sufficiently complete, was produced among the leading Athenians to enable the people after a certain time to dispense with that exceptional security which the ostracism offered. To the nascent democracy it was absolutely indispensable; to the growing yet militant democracy it was salutary; but the full-grown democracy both could and did stand without it. The ostracism passed upon Hyperbolus about ninety years after Cleisthenes, was the last occasion of its employment." (*Hist. of Greece*, vol. iv., p. 211.) This demagogue was as low in character as he was humble in birth; and the Athenians, thinking their own dignity, and that of the institution of ostracism, alike degraded by proscribing such a worthless individual, resolved to put an end to the practice. During the reign of ostracism in Athens, we read of about ten different persons as having been banished by that political measure. Among these are to be found some of the most illustrious names that that illustrious city ever knew. Witness Themistocles, Aristeides, Cimon, and Alcibiades. The story of Aristeides, "at all times just but when he signed the shell," recording his own name upon the tablet at the request of the illiterate peasant, is told by Plutarch (*Arist.* c. 7), and is well known.

With the exception of the statement of Aristotle in his *Politics* (iii. 8), respecting the abuse of ostracism for party purposes, we have no means of judging of its administration at Argos, Miletus, and Megara, the other democratical states in which the system of the shell prevailed. The *Petalism* (πέταλον, *a leaf*) of the Syracusans was borrowed from the ostracism of the Athenians, which it closely resembled, except that the names were written on *olive leaves* instead of potsherds, and the term of banishment was only for five years. It should not be omitted, however, especially in connection with the views of Mr Grote, that petalism seems to have proved self-destructive in Syracuse. The fear of this "humbling of the pride and hopes of the exile" deterred the best men among the citizens from taking any part in public affairs, and, as a necessary consequence, elevated the unscrupulous and incompetent to power. Misgovernment and political degeneracy was the obvious result; and petalism had to be repealed, B.C. 452. (See Diodorus, xi. 87.) In reference to this significant fact Grote offers the reflection, that "we cannot safely infer, that because the ostracism worked on the whole well at Athens, it must necessarily have worked well in other states;" a remark quite just in itself, but nevertheless laying bare the weakness of the system; and by no means calculated either to recommend the policy of its adoption or to vindicate the superior wisdom of its institution. Plutarch affirms that ostracism arose from the inherent envy and jealousy of a democracy (*Themist.* 22, and *Arist.* 7); and the majority of critics, both in ancient and modern times, have been all but unanimous in denouncing it. And if Grote is chargeable with carrying his vindication of ostracism too far, he has at least the merit of placing in a full and clear light the peculiar excellences in the system which doubtless recommended its adoption to the enthusiastic republicans of Athens.

OSTROG, a town of European Russia, capital of a district of the same name, in the government of Volhynia, stands on the Vilia, 103 miles W. of Jitomir. It has an old castle, several Greek and Roman Catholic churches, a convent, and school. Several markets are held here; and an active trade is carried on. Pop. (1850) 9353, many of whom are Jews.

OSTROGOSHSK, a town of European Russia, government of Voronesh, on the left bank of the Tosna, about 60 miles S. of Voronesh. It is a thriving town, and contains several churches. Commerce is actively carried on; and several fairs are held. About 10 miles off is a colony of German Protestants, who live chiefly by agriculture. Pop. (1851) 5622.

OSTROWO, a town of Prussia, government of Posen, and 67 miles S.E. of that town. It has Roman Catholic and Protestant churches, a synagogue, and a grammar

school. The manufacture of woollen cloth is busily carried on. Pop. 5839.

OSTUNI, a town of Naples, province of Otranto, stands on a hill, 21 miles N.W. of Brindisi. It is the see of a bishop; and contains numerous fine churches and large convents. Pop. 6000.

OSUNA, a town of Spain, province of Seville, at the entrance of a valley, not far from the Salado, 40 miles E.S.E. of Seville. It is built in a semicircular form on the slope of a hill, and has broad regular streets, well paved, and adorned with numerous fountains, which are supplied with water brought from the distance of one mile by an underground channel. On the top of a hill stands a castle, which commands an extensive view of the fertile country in the vicinity of the town. The collegiate church is a building in the mixed Gothic and Cinquecento styles, and contains several fine pictures by Ribera. The church having been occupied as a fortress by Marshal Soult, these, as well as the sculptures over the portal, have been much defaced by his soldiery, and a large quantity of ancient plate was carried off. The vaults, which are supported by Moorish arches, contain the tombs of the Giron family, by one of whom the church was founded in 1534. The university, which formerly existed at Osuna, was suppressed in 1824; but there is still a college, which is a stately building with a large quadrangle. There are, besides, numerous elementary schools, and several hospitals. In the environs of Osuna, there are many hermitages and public walks. A great number of the inhabitants are engaged in agriculture; but there are also numerous manufactories of iron, earthenware, bricks, oil, hats, linen, &c. Many mats are also made from Spanish broom; and this sort of work employs a large number of the poorer people. Wheat, barley, and beans are exported in large quantities to Seville and Malaga. Pop. 15,508.

OSWEGO, a town of the United States of North America, state of New York, built on both sides of the Oswego River, where it enters Lake Ontario, 35 miles N.N.W. of Syracuse, and 183 N.N.W. of Albany. The river, which is here about 230 yards broad, is crossed by a bridge. The houses and public buildings are handsome; and the streets are straight, broad, and regularly laid out. Oswego has eleven churches, two of which, belonging to the Presbyterians, are remarkable for size and elegance. There are also a court-house, custom-house, two banks, an academy, and other educational institutions. Several newspapers are published in the town. The river, which has falls a short distance above the town, affords water-power for the various manufactories of the place, consisting of ten or twelve large flour-mills, and a starch factory employing about 100 hands. The commerce of Oswego is extensive, and rapidly increasing; its position gives it great advantages for intercourse with Canada, nearly half of the trade of the United States with that country passing through Oswego. The imports from Canada to this port in 1855 amounted in value to more than L.1,250,000; and the whole value of imports and exports in that year was about L.8,000,000. The harbour is one of the best on the United States side of the lake, having a pier 1200 feet in length. On the E. side of the river stands Fort Oswego, built by the government for the protection of the town and harbour. The shipping of the port, enrolled and licensed, had in 1852 a total tonnage of 26,107; and during the year ten ships were built, with a tonnage of 765. In the same year the vessels that entered were 1784, tonnage 240,253; those that cleared were 1731, tonnage 234,625. Pop. (1850) 12,205; (1855) estimated at 16,000.

OSWESTRY, a municipal borough and market-town of England, Shropshire, on the borders of Wales, 20 miles N.W. of Shrewsbury, and 171 miles N.W. by W. of London. It was formerly surrounded by walls, portions of which still remain. Some of the houses are of great antiquity; but the greater number are of modern erection, built chiefly of brick. The streets are clean and well paved. Of the public buildings, the principal are—the church with its high ivy-covered tower, the town-hall, theatre, and small jail. Another church has been recently erected; and there are several dissenting places of worship. Oswestry has several schools, a savings-bank, dispensary, &c. Flannel and coarse linen cloth are manufactured in small quantities; and in the vicinity there are coal mines, and paper and corn mills. Races are held annually in September; and there are several yearly fairs. A considerable retail trade is carried on with the surrounding country. Oswestry is supposed to derive its name (originally *Oswaldstree*) from Oswald, King of Northumbria, who was killed in battle here in 642. It was of great importance in early times, as one of the keys of Wales. On a hill to the west of the town are the remains of a castle, supposed to be as old as the Norman Conquest. Pop. (1851) 4817.

OTAGO. See New Zealand.

OTAHEITE. See Tahiti.

OTHMAN IBN AFFAN, the third of the Moslem caliphs, was a descendant of Abd-al-Menaf, one of Mohammed's ancestors. He first appears prominently in history as one of the secretaries, and the son-in-law of the prophet. The next important event in his life, his appointment to be one of the six commissioners for the election of a successor to the Caliph Omar, was the immediate cause of his elevation to power. The six agreed to choose one out of their own number; their choice fell upon him; and he began his reign in 643. It soon became evident that Othman's vice of favouritism, and his inattention to the wishes of his subjects, were checking the growing prosperity of Mohammedanism. By means of his lieutenants, indeed, he completed the subjugation of Persia, rendered the island of Cyprus tributary, and successfully maintained the Moslem cause against the Greeks. But his civil administration meanwhile was by no means successful. Efficient governors of provinces were recalled in order to give place to his worthless friends; the contents of the public treasury were lavished upon his minions; he had the misfortune to lose the prophet's silver signet-ring, which was considered the palladium of the empire; and he had the indiscretion to beat almost to death Ammar Ibn Jasir, a zealous Moslem, who had denounced his injudicious government. The consequence was, that there was excited in the hearts of his subjects a settled enmity which ultimately led to his ruin. At the end of about twelve years, Medina was invested by a strong force of rebels; delegates with lists of grievances from the misgoverned provinces fanned the flame of insurrection; and the deposition of the caliph was pertinaciously demanded. The suppression of this rebellion by means of concessions only made Othman's inveterate enemies take more insidious and more deadly measures. His treacherous secretary, at the instance of Ayesha, the prophet's wife, despatched to Egypt false letters of state commanding the death of Mohammed, the son of Abubeker. Mohammed, intercepting these letters, vowed vengeance against the caliph, and forthwith repaired to Medina at the head of a determined band of followers. The city was entered without opposition; the palace was taken by storm; and Othman, with the Koran in his bosom, fell beneath the blows of several assassins in 656.

Othman, or *Osman*, the founder of the Ottoman Empire, was born in Bithynia in 1259. He is said to have been the son of Orthogrul, the chief of a pastoral and predatory horde of Turkomans, who had permanently pitched their tents in the territory of the Sultan of Iconium. At any rate, it is certain, that on the death of Masud II., the last of the Seljukian dynasty, he was at the head of the above-

mentioned tribe, and was ready to begin the project of founding a kingdom. Part of Bithynia, a fragment of the dismembered empire of the sultans of Iconium, was immediately seized; a government was established; coins were struck in the city of Cara-Hissar; and on the 27th July 1299 he led his invading forces down through the unguarded passes of Mount Olympus into the territory of Nicæa. The conquest advanced slowly but successfully for the next twenty-seven years. The hardy robber-chief, after repeated incursions, began to gain ground upon the Greeks; captives and volunteers soon swelled the number of his troops; he was then enabled, by means of garrisons, to secure every post as soon as it was taken; the different districts of Bithynia came successively under his power; and the foundation of the Ottoman Empire was completed by the capture of Prusa in 1326. Othman had just time to hear the news before he died, leaving his sceptre to his son Orchan. (See TURKEY.)

OTHO, MARCUS SALVIUS, a Roman emperor, was descended from an ancient Etruscan family, and was born A.D. 32. He was proclaimed emperor in 69; and he stabbed himself in the same year, ninety-five days afterwards. (See ROMAN HISTORY.)

OTHO or *Otto I.*, surnamed *The Great*, Emperor of Germany, was the son of Henry the Fowler, and succeeded his father in the throne in 936. The early part of his reign was occupied in simultaneously extending his power and supporting the cause of the church. In the course of a long series of civil broils his unruly vassals were subdued, and part of their wealth and influence was transferred to the abbeys and convents. He concluded a successful invasion of Denmark by compelling the Danes to become Christians; and he pardoned Boleslaus, the rebel duke of Bohemia, only on condition that all the Bohemians should receive baptism. After he had extended the limits of the kingdom of Germany on every side, Otho turned an ambitious eye towards Italy. An application from Adelaide, the widow of Lotharius, King of the Lombards, for aid against the treasonous usurper Berengarius, furnished him with an opportunity for executing his projects. He defeated Berengarius in 951, married Adelaide, and before departing to his own kingdom, was acknowledged by all the towns of Lombardy as their liege lord. His regular instalment in the sovereignty of the country took place in 961, when he returned flushed with the decisive victory which he had gained over the Hungarians at Augsburg. In that same year he was crowned at Milan with the iron crown of the Longobards; and in the following year he was crowned at Rome as emperor of the West by Pope John XII. Otho now proved that he was not unworthy to be the successor of Charlemagne. He vindicated his temporal jurisdiction over the supreme pontiffs; and, amid much resistance from the Romans, succeeded in establishing the law, that no pope could be chosen without the previous consent of the emperor. He also laid the foundation of municipal government by encouraging the growing spirit and enterprise of the citizens of the great Italian towns. The death of Otho took place in Germany in 973.

OTHO or *Otto II.*, the son of the preceding, was born in 955, and succeeded to the imperial throne on the death of his father in 973. His reign was occupied in maintaining by the sword those dominions which had been bequeathed to him. No sooner had he been crowned, than he was summoned to Germany to suppress the rival claims of his cousin Henry, Duke of Bavaria. After this rebellion had been suppressed, he involved himself in a war with the King of France touching the fief of Lorraine; and it was not until his army had been routed on the banks of the Aisne, and he had been forced to concede part of the disputed territory, that the contest was brought to a close. Then a revolt among the Romans, and the continued occupation of Calabria and Apulia by the Saracens and Greeks, recalled him to Italy, and drove him to take the most sanguinary measures. He entered Rome without opposition; overawed the malcontents; and, enticing the principal movers of the rebellion to a banquet, put them to death in cold blood. His defeat immediately afterwards by the Greeks and Saracens at Bassentello checked his success, but did not divert him from his determined course of action. He struck terror into the hearts of his disaffected subjects by surrendering the treacherous city of Benevento to the pillage of the soldiery. He was also preparing another expedition against the Saracens, when he was cut off in 983, a short time after his son Otho had been declared his successor by an assembly of the states of Italy and Germany.

OTHO or *Otto III.*, the only son of the preceding, was twelve years of age when his father died. During his minority civil broils, both in Italy and Germany, threatened the complete overthrow of good government. Yet, no sooner had he formally assumed the power, than he began to restore and maintain order with vigour and rapidity. In 996 he crossed the Alps at the head of a large army; forced his way into Milan to be crowned with the crown of the Lombards; and was invested with the imperial title by his relative Pope Gregory V. He then, in the following year, hastened northward to stem the incursions of the Slavic hordes of the Elbe and the Oder. The intelligence that a patrician named Crescentius was endeavouring to restore the old Roman republic, had expelled the pope, and had placed in the pontifical chair a Greek, with the title of John XVI., soon recalled him to Italy. Crushing the rebellion with relentless severity, he put the anti-pope to death by slow and savage tortures, and hanged Crescentius from a lofty tree. His next important action was the erection of Poland into a kingdom, on condition that it should be a fief of the empire. After this he undertook a successful campaign against the Saracens of Apulia and Calabria. He was then, in 1002, engaged in contending against a fresh revolt of the Romans, when the widow of Crescentius poisoned him. Otho left no children, and was succeeded by Henry, Duke of Bavaria.

OTHO or *Otto IV.*, the son of Henry the Lion, Duke of Bavaria, was duke of Saxony when in 1197 the Emperor Henry VI. died, leaving his crown to his infant son Frederick. Disregarding the true heir, the Guelphs conferred the imperial title upon Otho; while the Ghibelines conferred it upon Philip, Duke of Suabia. The former now commenced a series of ineffectual struggles to confirm his title. A civil war of eight years ended by placing his rival upon the throne, and by forcing himself to flee to his uncle, King John of England. Even after the assassination of the Emperor Philip had left him in possession of the empire in 1207; and after he had been formally crowned in Rome in 1209, his claims still continued unsettled. By the intrigues of Pope Innocent III., he was soon involved in a war with Frederick, King of the Two Sicilies, and the rightful heir to the imperial crown. The struggle in a short time was transferred from Italy to Germany; and in 1214 the cause of Otho was irretrievably ruined by the French king, Philip Augustus, at the celebrated battle of Bouvines. The remaining years of the degraded emperor were spent in privacy in the exercises of penitential devotion. He died at Brunswick in 1218.

OTHO, or *Otto, of Freysingen*, a celebrated chronicler of the twelfth century, was the son of Leopold, margrave of Austria, and of Agnes, daughter of the Emperor Henry IV. Although born in such a high sphere of society, he descended to the condition of an obscure scholar and a self-denying ecclesiastic. He studied at the universities of Nürnberg and Paris; entered the order of St Bernard in the abbey of Morimond; and in 1136 became abbot. His half-brother, the Emperor Conrad III., removed him to the

see of Freysingen in 1136. The rest of his life, with the exception of an interval during which he accompanied the imperial troops to Palestine, was passed in the assiduous and pious discharge of the duties of his diocese. He died in 1158, while on a visit to his old residence, the Abbey of Morimond. Otho left behind him a Latin chronicle of the world from the creation till his own time. Of the seven books into which it is divided, the first four are a mere selection of passages from Orosius, Eusebius, and others. It was published in fol., Augsburg, 1515. He was also the author of a treatise concerning the end of the world, and a history of the Emperor Frederick Barbarossa, entitled *De Gestis Frederici Ænobarbi Libri Duo*. This latter work is inserted in Muratori's *Rerum Italicarum Scriptores*.

OTLEY, a market-town of England, West Riding of Yorkshire, stands in a beautiful valley, on the right bank of the Wharfe, under Chevin Hill, 25 miles W.S.W. of York, and 205 N.N.W. of London. Though small, it is well built, and contains a large parish church, in the form of a cross, built in 1507, but retaining at present little of its original architecture. Besides this there are places of worship for several other denominations, a free grammar school, and other educational institutions. The chief manufactures of Otley are worsted, paper, and flour. There was formerly a considerable trade in woollen fabrics here, but that has disappeared; and cattle and corn are now the only articles brought to the market. Pop. (1851) 4522.

OTRANTO. See HYDRUNTUM; and SICILIES, *Two*.

OTTAJANO, a town of the kingdom of the Two Sicilies, province of Naples, stands at the N.E. base of Mount Vesuvius, 12 miles E. of Naples. It has a castle standing on an eminence, and three churches. Agriculture is the chief occupation of the inhabitants. Pop. 14,000.

OTTAWA, the recently-constituted capital of Canada, is situated on the right bank of the Ottawa River, 87 miles above its confluence with the St Lawrence, 95 miles N.E. of Kingston, and 126 W. of Montreal. It is divided into two parts by the Rideau Canal, which connects the Ottawa with Lake Ontario. These parts are called the Upper and Lower Town respectively. The canal joins the river by a series of good stone locks, and is crossed by a handsome bridge; but this mode of communication has now become quite insufficient for the increasing traffic. The streets are straight, broad, and regular, and the buildings handsome and uniform. There are six churches, belonging respectively to the Church of Rome, the Church of England, the Established and the Free Church of Scotland, the Wesleyans, and the Episcopal Methodists. There are also several educational, literary, and benevolent institutions. The principal source of the town's importance is the trade in timber, larger quantities of which are exported to Europe and the United States, through Ottawa, from the surrounding country, than from any other part of Canada. The vicinity of the town is remarkable for its grand and beautiful scenery; the falls of Chaudière on the Ottawa being second only, among American cataracts, to those of Niagara. This place was formerly called *Bytown*, but the name was changed in 1854. Pop. about 10,000.

The River Ottawa takes its origin in the interior of Lower Canada, in a series of lakes, which may be considered as mere expansions of the river. About 100 miles from its source it leaves Lake Temiscaming, the last of these; and separating Upper from Lower Canada, flows S.E. and E. until it falls into the St Lawrence at the island of Montreal. Its whole length is about 400 miles; and it is navigable as far as the town of Ottawa. It receives the Rideau from the right, and the Gratineau and Lièvre from the left. The scenery on its banks is of the finest description; but the land is not fertile.

OTTLEY, WILLIAM YOUNG, a critic and collector of paintings and engravings, was born in 1772. The unwearied enthusiasm for the fine arts by which he was distinguished through life soon began to appear. About his twentieth year he proceeded to Italy, and devoted both his time and means to the study of the great painters. Famous pictures were copied, fine engravings were collected, and numerous works of the early masters were purchased. Nor did his industry flag when he had returned to England, at the end of ten years, to turn his collections to some account. Among other splendid and costly works, he published *The Italian School of Design*, in 3 parts, 1808–12–23; and *A Series of Plates engraved after the Paintings of the most Eminent Masters of the Early Florentine School*, fol., 1826. As keeper of the prints in the British Museum he also laboured hard to arrange and classify the engravings in that institution. His death took place in 1836.

OTWAY, THOMAS, one of the foremost names in the English drama, was the only child of the Rev. Humphrey Otway, rector of Wolbeding in Sussex, and was born at Trottin, in the same county, on the 3d of March 1651. Passing from Winchester school, where he received his early education, he entered Christ Church, Oxford, as a commoner, in 1669. Little is known respecting his university career. He was not remarkable, however, for diligence in study, and seems to have cultivated society more than letters. He was intended for the church; but the death of his father, who left him no other inheritance, he tells us, but that of "faith and loyalty," compelled him to leave college without taking his degree. In these circumstances, he set out for London to push his fortune, without any more definite aim before him. For a needy youth of twenty, fond of pleasure and full of poetry, the metropolis was at that time anything but a paradise. Inclination drew him to the theatre, and necessity induced him to turn actor. He appeared on the stage for the first and last time in 1672, in the character of the "King" in Mrs Behn's drama of the *Forced Marriage*, at Sir William Davenant's theatre in Dorset Garden, Salisbury Court. "But he being not used to the stage," says Downes, "the full house put him to such a sweat and tremendous agony, being dash't, spoilt him for an actor." (*Roscius Anglicanus*, p. 43, 1789.) This was not encouraging for young Otway; but had not Shakspeare and Ben Jonson failed before him in the player's art? and why should not he succeed, like them, in writing dramas, if he could not act them? It took Otway three years to give a practical solution to this problem. Meanwhile he ran after rank and courted fashion, his gay wit and jovial disposition gaining him ready access to the society of the great. The witty and profligate John Wilmot, Earl of Rochester, the chosen patron of nearly all the vices, was likewise the patron of "Tom Otway;" and the ardent adventurer followed his chief into the wildest of his excesses. Sated for a time with the dissipation into which he was led, and perhaps tired of hanging by the skirts of dissolute men of fashion, he directed his attention to dramatic composition. His tragedy of *Alcibiades*, the first and the poorest of his productions, appeared in 1675, when Otway was in his twenty-fourth year, and met with some success. It was not borrowed from the French, as Johnson surmises (*Lives of the British Poets*); but it was written in rhyme, according to the absurd custom then much in vogue; and neither in sentiment nor in language did it give any promise of future eminence. His *Don Carlos* of the next year was a decided advance on his first attempt; but the extraordinary popularity to which it attained was owing more to adventitious circumstances than to the inherent excellence of the performance. Rochester was fond of playing the tyrant in literature; and having quarrelled with Dryden, who was too strong a man to submit to such despotism, his lordship, after various despicable attempts to ruin the fame of his rival, selected Otway as the most respectable antagonist he could find to pit against

Otway.

the sturdy laureate. Heralded by so great a name, *Don Carlos* became "the first heroic play of the age;" and, as the honest prompter tells us, "being admirably acted, it lasted successively ten days: it got more money than any preceding modern tragedy." (*Roscius Anglic.*, p. 46.) Dryden, as might be expected, had not the greatest reverence for the Prince of Spain; yet it says much for his candour, that, despite his animosity towards his young antagonist, he confessed that Otway had a power of "moving the passions" which he himself did not possess. Otway, meanwhile, in the flush of his sudden triumph, turned a satirical shaft against the laureate, and allied himself with Shadwell, the well-known "MacFlecknoe" of Dryden's famous satire. Otway's next contribution to the stage consisted of a tragedy and a farce, both translated from the French,—*Titus and Berenice* from Racine, and *The Cheats of Scapin* from Molière. These pieces were performed together at Sir William Davenant's theatre in 1677, and had good success. During the same year Otway made bold to pay court to the comic muse in his *Friendship in Fashion.* Apart from other defects, it was a very immoral play; considered "very diverting" by the play-goers of the time; but hissed off the stage in 1749 for its indecency. (See Langbaine's *English Dram. Poets.*) It was obvious enough that the author was not qualified to shine in the comic drama.

In 1677 Otway exchanged the pen for the sword, having received a cornet's commission, through the Earl of Plymouth, the king's natural son, in a new regiment of horse destined for Flanders. Here again fortune played him false. The troops to which he belonged were soon after disbanded: the money designed for their pay was diverted to other purposes; and the unfortunate soldier had to be content with debentures at a very low credit. Otway returned, therefore, to his muse again, in a state of deplorable indigence and distress. Rochester was no longer his friend. That brilliant libertine made the unfortunate poet the butt of his malicious wit in a lampoon called *A Session of the Poets.* Otway had committed the mortal offence of presuming to rival his lordship in an attachment to Mrs Barry, a famous actress of the day, who never failed to draw tears from her audience in her representations of Otway's "Monimia" and "Belvidera." The poor poet's affection for this woman was tender, passionate, and enduring; and although unrequited, his letters to her display a pathos and eloquence not inferior to the finest passages in his tragedies. In 1680 he produced his tragedy of *Caius Marius*, in great part avowedly transferred from Shakspeare's *Romeo and Juliet.* The author had now ranged himself on the side of Dryden and the Tories; and he contrived in this play, as well as in *The Poet's Complaint to his Muse*, published the same year, to expose the violences of the opposite party. The promise which Otway had early given of rare pathetic power was fully confirmed in his *Orphan*, founded on a popular novel of the day, and represented in 1680. It is a domestic tragedy, drawn from middle life, not possessing great elegance or splendour of diction, but with a power of moving the heart unknown to any tragedy of that time. "This is one of the few plays," says Johnson, "that keep possession of the stage." Passing over his comedy of *The Soldier's Fortune*, acted in 1681, and its second part, called *The Atheist*, printed in 1684, both as poor as they were popular, we come to Otway's greatest performance. He was constrained to keep toiling for his daily bread; and this necessity tended to expand his genius and mature his powers. In *Venice Preserved* he had larger scope for variety and contrast of character, and a more elevated sphere for the display of his peculiar genius, than he had found in his *Orphan.* In strength of imagery and force of expression he had made a decided advance, but his former faults were still observable. As before, this play is deficient in fire and high imaginative power; it is sometimes false in sentiment, and often poor in poetry; but it possesses a power of melting quite unsurpassed in the English drama. "Nature is there," said Dryden, "which is the greatest beauty;" and Johnson has re-echoed the judgment. Addison says of him (*Spectator*, vol. i., No. 39) that he "shines in the passionate parts more than any of our English poets;" and Goldsmith, a little forgetful, perhaps, of the merits of some of our earlier dramatists, says that Otway was, "next to Shakspeare, the greatest genius England ever produced in tragedy" (*The Bee*, No. 7). "Gentlest Otway," as Collins sings of him, is certainly, with all his faults, the most pathetic of our dramatists. Time was gradually maturing his genius; and he was just emerging from the bewildering fevers of youth into clear poetic activity, when his unhappy career was brought to a close. Having retired from the importunate demands of his creditors to an obscure ale-house on Tower Hill, he was seized with a fever, occasioned by the violent pursuit of an assassin who had murdered one of his friends in the streets of London. This cut him off on the 14th of April 1685, at the premature age of thirty-four. The current story of Otway's having been choked by a crust of bread, which he eagerly swallowed when suffering from hunger, does not seem to be well founded (For further details respecting Otway's life, see the biography, prefixed to the best edition of his works, by Thomas Thornton, 3 vols., London, 1813.) Otway's minor poems do not possess very great merit.

At the time of his death Otway had completed four acts of a new tragedy, said to have been purchased by Bentley, his publisher. An advertisement for the recovery of the missing MS. appeared in L'Estrange's *Observator* for 27th November and 4th December 1686, but to no purpose. (J. D—S.)

Oude.

Extent and boundaries.

OUDE, or more properly OUDH, a compact and important province of Hindustan, lies between N. Lat. 25. 34. and 29. 6., and E. Long. 79. 45. and 83. 11., and is now about 270 miles in length from N.W. to S.E., and 160 in breadth. The area is computed at 23,738 square miles, by Thornton; but Butter makes it 23,923, and by some it is raised to 25,000. Exact statistics, however, of the province in this or other particulars are not yet procurable. It is bounded on the N. and N.E. by Nepaul, on the N.W. by Rohilkhand (Rohilcund), on all other quarters by provinces which have at various times been wrested from it by the English,—viz., on the E. by Gorakhpúr (Goruckpore), on the S.E. by 'Azímgarh (Azimgurh) and Jaunpúr, on the S. by Allahabad, and on the S.W. by Fathpúr (Futtehpoor), Kánhpúr (Cawnpoor), and Farrukhábád (Furrukhabad), districts of the Doab.

General aspect of the country.

The general aspect of the country is that of a fertile plain, being, in fact, a continuation of that immense level valley which extends in a curved line from the sources of the Western Banás River, in E. Long. 73. 28., to the junction of the Ganges and the Brahmapootra, in E. Long. 90., a distance of 1100 miles. Along the eastern frontier, from a few miles north[1] of Bahraich, begins the great Taráí Forest—marshy, and in some places almost impassable, but nevertheless studded with the strongholds of the great baronial landholders, as the Raja of Tulsípúr. The plain of Oudh slopes gently at the rate of about 7 inches in the mile to the E.S.E. The only irregularities on its surface are caused by the greater or less resistance of its soil to the rivers which traverse the province, and of which the five principal are the Ganges, Saí, Ghúmtí, Deohá, and Raptí. The courses of these streams are almost parallel, and the order in which they are here named is the order of their succession from W. to E. The Ganges then forms the

[1] Sleeman's *Journey*, vol. i., p. 36.

Oude. western boundary of Oudh; the Saí, which comes next, unites with a western branch called the Lon, a little above Râe Barelí, and falls itself into the Ghúmtí in about N. Lat. 25. 30. The Ghúmtí is the river which washes Lucknow (Lakhnau), and passes through the centre of the province of Oudh. Faizábád, the ancient capital of Oudh, is situated on the Deohâ, which has two other names, the Sarjú and the Ghágrâ; and to the E. of this, and on the extreme E. of the province, is the Raptí, also called the Airavatí. These rivers are the principal cause of the great fertility of Oudh; but it is remarkable that they are decreasing in volume in a way which may well lead to grave apprehensions. Everywhere the wave-worn marks on the banks, much above the highest level to which the waters now attain, attest the decrease which is going on. It is a historical fact, that in 1773 Sir Robert Barker's brigade sailed *over* the famous stone bridge at Jaunpúr; and within the last fifty years the Ghúmtí has fallen 5 or 6 feet. Were the great tracts of jungle, which with provident care have been fostered by the Oudh government, to disappear, it cannot be doubted that the rivers would be still farther diminished by the cutting off of all the small streamlets, which are at present nourished by the moisture collected on the leaves of the forests, and which serve as feeders to the principal streams. The vast quantity, also, of sand and dust which during the hot season is brought by the westerly winds, would, but for the jungles, gradually overlay the country, and turn what are now expanses of verdure into dry deserts. Even now the old inhabitants of the country assert that the deposit brought by the *lúk* or hot wind is greater, and the heat of the wind itself fiercer, than in former times; and this may well be the case, from the extensive clearance of jungle which has everywhere taken place in the adjacent British districts. European observers record the fact, that it is now requisite to dig wells deeper than in times within the memory of man; and that the annual fall of rain, though extremely irregular, is upon the whole gradually diminishing.

Soil. The soil of Oudh is the finest in India;[1] and from the numerous rivers which flow through the country, the water is everywhere near the surface. Sleeman conjectures[2] that the whole province once formed part of the bed of a lake which contained a vast fund of soluble salts (nitrates of ammonia), which, combining with magnesia, lime, soda, potash, alumina, and oxide of iron, form double salts, become soluble in water, and are fit food for plants, to the growth and perfection of which they are all more or less conducive. According to the distribution of these salts, the soil may be divided for agricultural purposes into *matiyár*, *domatiya*, *bhúr*, and *úsar*. Of these, *matiyár*[3] is a rich clay soil, mixed with a small proportion of sand, or one-tenth of silex; the rest alluvial mould. It differs from the *domatiya* in containing a greater proportion of those elements which constitute what are called good clay soils. It is more capable of absorbing and retaining moisture, and of fixing ammonia, than the *domatiya*, of a darker colour, and forms more into clods. The *domatiya* is of a light-brown colour, soon powders into fine dust, and requires much more outlay in manure and labour. It has a considerable admixture of sand, and in some places about $\frac{1}{10}$th of lime. The *bhúr* consists of $\frac{7}{10}$ths of sand and the rest clay; and being not retentive of moisture, is far less productive than the two classes of soil above mentioned. Lastly, the *úsar* lands, having a superabundance of salts, are more or less unfit for cultivation; but in general, if flooded with rain-water for two or three seasons by means of artificial embankments, and then well watered, manured, and ploughed, will bear tolerable crops. From the worst *úsar* soils common salt or saltpetre, or both, are made by washing the earth, and removing the water by evaporation. The most important feature in the soil of Oudh is the abundance of *kankar*, nodules formed of the elements of chalk and oolite, which opposes such resistance to the rivers as to keep them in permanent banks, thereby insuring a perfect drainage of the country; and when an exit is once established from a hollow, the channel gradually deepens until the hollow is perfectly drained. In patches of ground where *kankar* largely predominates, are found the only irregularities of surface noticeable in Oudh. Ridges are thus formed 70 or 80 feet above the surrounding country, the less coherent materials of whose soil has, in the course of ages, been swept away by the agency of wind and water. Hence, too, the channels of the rivers have gradually deepened, so that the surface of the water is never less than 20 feet below the level of the bank, and in many places as much as 80. The Ghúmtí is intersected at every 4 or 6 miles by *kankar* ridges of 2 or 3 yards in width, which, in the dry season, sometimes diminish the depth of water to 2 feet. The right bank of this stream from Pálí to Sultánpúr, a direct distance of 40 miles, but nearly double as much if the windings of the river are followed, consists of solid *kankar*, and resembles in miniature the mountain ranges on the right bank of the Jumna and Ganges. The left bank is low and sandy, and these remarks apply also to the Deohâ: but in both cases the stream sets against the high bank, and has therefore no tendency to spread. Oude.

Rivers and marshes. The principal rivers have been already named in describing the configuration of the country, and the effect of the tenacious *kankar* upon their streams has been noticed. The next remarkable point regarding them is the singular multiplicity of their windings, from which feature, indeed, the Ghúmtí derives its name. The water of this latter stream becomes unfit for drinking during the rainy season, owing to the immense quantity of yellow clay with which it is loaded. When epidemics prevail at Lucknow, or generally along its banks, a putrid scum forms on the surface of this river, owing to the multitudes of dead bodies which are thrown into it. Yet it abounds in fish; and thus supplies one-fifth of the population with a considerable portion of their diet,[4] especially during the rains. The Ghúmtí has a total course of 482 miles, rising in the district of Shahjehanpore, in N. Lat. 28. 35., and falling into the Ganges in N. Lat. 25. 29. It enters the territory of Oudh about 96 miles from its source, and after a course of 250 miles, crosses the frontier into the British district of Jaunpúr. During the rainy season boats of 4 or 5 tons weight can go up to Lucknow, but all supply-boats return from that city empty. The Ganges and Derhâ are usually open at all seasons for the largest class of boats. Their annual rise is about 30 feet, their courses are comparatively straight, and their currents proportionally rapid during the freshes. The Ganges has a low bed, 4 miles in average width, within the limits of which it changes its course annually. The Deohâ or Ghágrâ has its latter name from a Sanscrit root which signifies "to gurgle," and is a considerable river, equal, indeed, in volume and rapidity to that part of the Ganges which runs parallel to it. Its total course is 606 miles from its source in Kumaon, in N. Lat. 30. 28., to N. Lat. 25. 46., where it falls into the Ganges. At 181 miles from the point where it rises it first touches the Oudh territory, which it continues to bound for a distance of 316 miles. The Saí is, in the rains, navigable for boats of a ton or a ton and a half as far as Râe Barelí, above which point there is no trade carried on. This river winds exceedingly, and the route by the Ganges or Ghúmtí is therefore preferable. At Râe Barelí the Saí is as broad as the Ghúmtí, but only half the depth. It abounds in fish,

[4] Butter's *Topography of the Southern Districts of Oudh*, p. 12.

Oude. of which all classes partake, even the Brahmins, except those that are pundits. The Tons, Teons, Marhá, or Bisohí, is a branch of the Deohá, which it leaves 5 miles above Faizábád; and after uniting with the Little Tarjú, runs into the Ganges 10 miles below Buxar. A cross branch, the Khajuhá Tál, 15 miles below Faizábád, again unites the Tons with the Deohá; and during the dry season is embanked at different points for irrigatory purposes. This has a most prejudicial effect on the climate, however beneficial it may be in another point of view. The Tons is not navigated above 'Azímgarh. The Son rises near Sháhábád, and running midway between the Ganges and the Saí, falls into the latter about 3 miles above Ráe Barelí. During the rains it is a considerable torrent, but at no time navigable.

There are no large permanent lakes in Oudh, but in the rains large *jhils* or collections of water, shallow but extensive, are formed, and, in the hot weather, dry up or are drained off by the water-courses. The largest of these is situated 8 miles N.W. of Mánikpúr, in the deserted bed of the Ganges, and is 16 miles long and 8 broad. The town of Betáganw, at its N.W. extremity, is the most unhealthy spot in Oudh, owing to this vast marsh, and the neighbourhood is infested with mosquitoes to an intolerable degree. It always contains water, and much rice is planted along it towards the end of March.

Climate. The climate of Oudh, more especially of the southern portion, is chiefly characterized by its dryness. Being beyond the equalizing influences of the sea-breeze, it is marked by extremes of heat and cold, the temperature at one time rising to 112°, and at another sinking to 28°. The mean daily range is 30°, and the mean temperature 74°. The annual fall of rain is very irregular, varying from 70 to 30 inches, and extending over a period of from four to two months. The gradual diminution in the quantity of rain is remarked by all the inhabitants of Oudh, and in places where grass formerly grew tall enough for thatch, it now scarce supplies pasturage for animals. Hoar-frost used to happen once in every ten or fifteen years; but within the last half century the recurrence of it has become much more frequent, and is now almost annual. West winds blow about 200 days in the year, and east winds during the remainder. The former winds are dry, and cold, or intensely hot, according to the season of the year, and loaded with fine sand. The easterly winds are damp, and bring with them the malaria of Bengal and Assam. During the hot weather the air is so loaded with particles of dust or sand as to curtail the view, and give a grayish aspect to the sky. But towards the end of the rains the atmosphere becomes highly transparent, and the Himálaya Mountains are seen at a distance of 200 miles. The sky is then of the brightest blue, and the phenomenon of converging rays in the quarter opposite to the rising or setting sun is not unfrequently seen in great perfection. The cold season extends over November, December, January, and February, and few climates then equal that of Oudh. Throughout these four months the nights are cold; and in January the cold is sometimes so great that thin ice is formed on shallow pools of water. By filling shallow vessels with water, and protecting them from the heat of the earth, and the warmer strata of air, ice is easily obtained during this and the following month. Fires are required during part of December, and in January and February, and during this period the fruits and vegetables of Europe are produced in great perfection. The hot weather begins with March, but the mornings are pleasantly cool till the middle of May. The hot winds usually commence in April, but in general abate towards sunset, so as to admit of riding or driving without discomfort. Sometimes sudden storms occur at this season from the north-west, which are attended with phenomena terrifically grand. An immense gloomy arch of clouds is formed, which assumes the appearance of a gigantic wave about to break over the earth. The sun gives to the summit of this wave a reddish-brown colour, and a rolling motion is observed in it like the smoke of artillery. When the storm is about a mile distant, a dead stillness prevails. As it approaches, eddies of wind toss leaves and branches on high, and the temperature falls twenty or thirty degrees. A continued roll of thunder has been heard from the commencement of the storm. This is now suddenly mixed with the rushing sound of the tempest, and so thick is the dust that all nature is shrouded in pitchy darkness. The fury of the wind is so great that trees are torn up, buildings demolished, and in spring-harvest the produce of whole fields is swept away. Occasionally hail falls in globules an inch in diameter, destroying tiled roofs, and stripping the trees of their leaves and branches. Sometimes neither rain nor hail falls, but in all cases the air is cooled and purified. The lightning is terrific, and but too often fatal to life. At the height of the hot season, and during the hot winds, which are called by the natives *lúh*, travellers fall dead from the heat.

The rainy season commences generally about the 15th of June, and lasts till the middle of October. The first fall is very violent, often from 8 to 10 inches in forty-eight hours, and is accompanied by strong winds which bring down the frail tenements of the natives in every direction. As the rains become sparse and uncertain in September, there is considerable insalubrity owing to the rapid exsiccation of the water-courses and marshes. October is hot and unhealthy, and the sun is not to be encountered with impunity till the beginning of November, when, as has been said, the temperature cools, and the climate becomes one of the most delightful known to man.

Zoology. In the great forests of the Taráí, elephants, tigers, and rhinoceroses are very numerous, and very destructive to human life. The tiger is also found in different jungles throughout Oudh; and the kings of Oudh have in general taken great interest in hunting that animal. Wolves are beyond measure numerous and daring, and destroy scores of children every year. A full-grown wolf stands ten hands in height, and will singly attack and kill a strong man. The natives have a superstition against spilling the blood of these animals, and say that the family of the wolf-slayer is certain to become childless; "a village community within the boundary of whose lands a drop of wolf's blood has fallen believes itself doomed to destruction." The lowest class of natives, who correspond to the gipsies of the West, seldom catch wolves, though they know their dens, and could easily dig them out, as they do other animals. It is supposed that they abstain from destroying wolves on account of the profit they make from the gold and silver bracelets, and other ornaments, worn by children who are devoured by these animals. The ornaments are frequently found at the entrance of the dens, and the people referred to are in the habit of searching for them. Sir W. Sleeman[1] records some surprising but well-authenticated stories of infants carried off and nurtured by the wolves. In particular, he mentions the case of a boy who was captured in the den of a wolf near Chandúr, and whose habits were entirely those of a wild beast. He lived three years after his capture, and was in the charge of Captain Nicholetts, the European officer commanding the 1st regiment of Oudh local infantry at Latampúr. He died in August 1850; was never known to laugh or smile; and only spoke once, when he asked for water a few minutes before his death.

Other wild animals are—the hyæna, jackal, wild hog,

[1] Vol. i., pp. 208, 211, 214, 215; ii., p. 60.

Oude.

nilgae, antelope, wild cat, porcupine, fox, hare, otter, mongoose, squirrel, rat, musk-rat, mouse, and flying-fox. The wild buffalo is found in the high j'hau jungle which clothes the banks of the Ganges in Bainswârá, and in a few of the large forests in the interior. The birds are—the adjutant, crane, partridge, quail, vulture, hawk, kite, crow, raven, jay, parrot (excessively numerous and destructive to crops), paddy-bird, maina, swallow, sparrow, dove, cuckoo, lark, kingfisher (many splendid species), wild goose, wild duck, woodpecker, and a species of Cinnyris, similar to the humming-bird of America. There is a great variety of fish. Porpoises are seen in the Ghúmtí only during the rains. Two species of crocodiles are found in the Ganges and Deohá at all seasons, but venture into the smaller rivers only in the rains. Snakes and lizards abound; the most venomous are the cobra and *karait*. Scorpions, centipedes, locusts, the sand-fly, eye-fly, and white ants, are among the most troublesome of the crustaceous and insect classes. The cochineal insect is sometimes seen on the prickly pear bush.

Domestic animals are numerous. Large flocks of sheep and goats are bred for the supply of the surrounding provinces. The price of a sheep is from 9d. to 1s. A milch goat sells for 2s., and one out of milk at from 10d. to 1s. Bullocks are exported at from L.1 to L.2 the pair, which is the common price in Oudh. A she-buffalo or two, or a cow or two, are kept by almost every person of substance, whether villager or townsman.

Natural produce.

The chief crops are,—the *Sinapis dichotoma*, *Cicer arietinum*, wheat, barley, beans, linseed, safflower, *Paspalum frumentaceum*, *Cynosurus corocanus*, millet, cotton, maize, *Holcus sorgum*, *Holcus spicatus*, *Phaseolus maximus*, *Cytisus cajan*, sesamum, and rice; which are reaped in the order in which they are now mentioned, beginning with the end of February. Sugar-cane is grown in small patches here and there, particularly between the Saí and Ganges, but there is but little sugar made. The same is the case with indigo; and though many districts, particularly about Faizábád, are most favourable to the poppy, the production of opium is comparatively small. Dr Butter, however, expresses an opinion, that the time is not far distant when the growth of opium will constitute one of the principal sources of the revenues of Oudh. The cotton produced in Oudh is nearly the same in quality as that of Bandalkhand, but is not so long in the staple, nor so soft. The rice of Oudh is described in the Institutes of Akbar as incomparable for whiteness, delicacy, perfume, and digestiveness.

Oudh has long been renowned for its groves of fruit trees, in the vicinity of which is excellent pasturage. The principal trees are—the mango, tamarind, banyan, *pípal* or *Ficus religiosa*, and the *mahúá* or *Bassia latifolia*, the flowers of which are sweet, and yield by distillation a spirituous liquor. The nuts also of this tree are valuable, as producing an oil which is used instead of butter. In the district of Bainswârá, and near Faizábád, forming a marked exception to the rest of Oudh with respect to the decay of arboriculture, extensive plantations have been lately made, chiefly of the *mahúá*, but in less proportion of the mango, the *Ficus glomerata*, the *Eugenia jambolana*, the *Melia Azadirachta*, the jack-tree, the *Artocarpus lacucha*, and *Phyllanthus emblica*. The *mahúá*, the *Eugenia jambolana*, mango, and *Melia Azadirachta* are the only trees fit for building. The *Cedrela Toona*, which furnishes a yellow dye, the *Ficus venosa*, and the bamboo, are also common in many parts of Oudh. The bamboo, however, will not grow in high *kankar* soils.

Territorial divisions.

The territory of Oudh, which in 1775 was among the largest and wealthiest provinces in India, extending from Mirzapúr, in 25. N. Lat., on the S., to Haridwár, in 30. N. Lat., on the N., and from Kánhpúr (Cawnpore) on the W. to Nepal on the E., now comprises but twelve *chaklás* or counties, and is shrunk to one-third of its former size. The *chaklás* are, beginning from the S.W. and S., and proceeding to the N.E. and N.,—1. Ahládganj; 2. Pratápgarh; 3. Sultánpúr; 4. Aldemau; 5. Salon; 6. Bainswárá; 7. Pachhamrát; 8. Lakhnau; 9. Rasúlábád; 10. Khairábád; 11. Gondá-Bahráich; 12. Sándí. The *chaklás* are again subdivided into *parganahs* or districts, sometimes compared to our baronies.

Chief towns.

The principal cities in the twelve *chaklás* are the following:—Mánikpúr, in Ahládganj, is a decayed city, once the capital of a principality, which extended over a large portion of Southern Oudh. It is situated on the left bank of the Ganges, along which it extends for upwards of a mile. The population is now about 10,000, of whom one-half are Muslims. The fort on the bank of the river, now in ruins, but once strong, extensive, and built of brick hardened by fire, resembles that of Allâhábád. Pratápgarh, or Belhághát, 2 miles W. of the Saí River, is the chief city in the *chaklá* of Pratápgarh. The population is about the same as that of Mánikpúr. It is surrounded with a decayed wall of sun-dried bricks, and on its western side is a ruinous citadel of the same material. Until 1834 there was a cantonment for a Company's regiment, with two guns, 3 miles to the N.E. of the town, in an extremely healthy spot. Sultánpúr, the capital of the *chaklá* so called, in N. Lat. 26. 16., E. Long. 82. 8., is a ruined city, about a mile from the eastern bank of the Ghúmtí River, 92 miles S.E. of Lakhnau. The inhabitants do not number 2000, and are nearly all Muslims. The town is built on the site of the capital of an aboriginal people called Bhars, now extinct, but whose possessions once extended to Allâhábád, Banáras, Faizábád, and almost to Lakhnau. Their capital, called Kasbháwanpúr, was 8 miles in circumference; and having been taken through a stratagem by Sultán Bádsháh Kaikubád, of the dynasty of Ghaur, between the years 1286 and 1289 A.D., he razed it to the ground, and built a new city,[1] which he named after himself. Some remains of the Bhar city are said to exist in the mound called Majhárgánw, in the middle of the city, and two wells at its southern verge. On the summit of the mound, which is formed of the debris of the palace of the Bhars, is a fort built by Kaikubád. Tándá is the most thriving town in the *chaklá* of Aldemau, being the seat of the chief cloth manufactories in Oudh. The population is about 6000, of whom the greater portion are weavers. The town stands about a mile from the western bank of the Ghágrá River. Ranjítpúruá is the capital of Bainswárá, and has a population of nearly 60,000, of whom one-third are Muslims. There is a fort of unburnt bricks, and two or three of the King of Oudh's regiments were always quartered in this city. Cutlery is the chief manufacture. Ráe Barelí, in Bainswárá, one of the most healthy spots in Oudh, was once a city of upwards of 50,000 inhabitants, but this population has now dwindled to 8000. Extensive manufactories of cloth once existed here. The fort is of solid masonry, a mile in circumference, with a dry ditch 50 feet wide and 25 feet deep. The walls are 8 feet thick, 50 feet high on the outside, and 25 feet inside, and have 24 bastions. The description just given applies also to the fort of Dalamau, which is an ancient city of Bainswárá, having a population of 10,000, on the eastern bank of the Ganges, about 40 miles to the N.W. of Mánikpúr. Salon, which gives its name to the *chaklá* so called, is a town with 2000 inhabitants, 3 miles to the W. of the Saí River. It originally belonged to Kánhpúríya (or, according to Sleeman, Kumpureya[2]) rájpúts; but they were dislodged for rebellion, by the núwáb Asifu'd-daulah, who granted the town and its attached lands to a fakir named Miyán Pír 'Atá, for the perpetual support of a religious eleemosynary establishment.

[1] Sleeman's account differs, see below, under "Inhabitants."

[2] Sleeman's *Journal*, vol. i., p. 247.

Oude.

The revenue is about 42,000 rupees a year, of which 30,000 are expended by Sháh-panáh 'Atá, the descendant of Pír 'Atá, in alms to Hindú and Muslim itinerant mendicants. Tiloí, in the same *chaklá*, is a town 55 miles S.E. of Lakhnau, with a population of 10,000. It is remarkable as the residence of a chief who is the lineal representative of the ancient kings of Oudh, a family which dates perhaps thirty centuries back. In the *chaklá* of Lakhnau (Lucknow), besides the capital of Oudh, which, before the late troubles, contained a population of perhaps half a million (stated by Heber[1] at 300,000), there are no towns of great note. In Pachhamrát is the city of Faizábád; and adjoining it, on the east side, the remains of the renowned and world-old city of Awadh, or Ayodhya (from *a*, "not," and *yudh*, "to make war,"—"the inexpugnable" in Sanskrit), the capital of the divine Rámah. There are still 8000 inhabitants in this most ancient city; and houses extending along the River Ghágrá or Sarjú, connect it with Faizábád. Sa'ádat'Alí, the first núwáb of Oudh, made Faizábád his residence, and built a palace there in the year A.D. 1730. His successors, Saffdar Jang and Shujá'u'd-Daulah, further embellished the city; but when the latter acquired Rohilkhand, he removed the seat of his government to Lakhnau. This was in 1775, and the population of Faizábád from that time began to decrease, but is still 100,000, of whom about one-tenth are Muslims. The chief manufactures are cloth, metal vessels, and arms. The Hindús call the city *Banglá*, which signifies "residence," and *Ayodhya*, which latter appellation properly belongs to the ruined city adjoining Faizábád on the E., as above mentioned. Rasulábád and Miyánganj, the two chief towns of the *chaklá* called after them, are situated 3 miles from each other, and about 30 miles to the W. of Lakhnau. Miyánganj was built by the famous eunuch Miyán Almás 'Alí Khán, minister of Sa'ádat 'Alí II., and, according to Sleeman, "the greatest and best man of any note that Oudh has produced."[2] On being visited by Sa'ádat Alí at this place, he built up a throne of a million of rupees, and after the núwáb had taken his seat upon it presented it to his highness. Almás built here a large fort with eight circular bastions, surrounded at 500 feet distance by a mud fortification with great Gothic gateways. The whole intervening space was planted with mango trees, of which there were magnificent avenues in Heber's time. The *chaklá* of Khairábád contains several large and populous towns. Of these, Khairábád, from which the *chaklá* has its name, is distant from Lakhnau 62 miles N.W., and lies in N. Lat. 27. 32., E. Long. 80. 49. Tieffenthaler speaks of it eighty years ago as populous, and situated in a plain abounding in fruit trees, the cultivation of which yielded L.120,000 annually. Six miles to the N.W. of this stands Sítápúr, where the 41st Bengal Native Infantry mutinied and murdered all Christian and other Europeans. Sandílá is a large and populous town,[3] 30 miles N.W. of Lakhnau, with many good houses of burnt brick and cement. Thirteen miles N.W. of this is Hatyá Haran, which is held sacred as the spot where Rámah purified himself from the sin of having killed a Bráhman in the person of Rávan, King of Ceylon. Misrik, a few miles from Hatyá Haran, is another very holy place, and celebrated as the residence of the sage Dadhích, with the bone of whose leg the gods defeated the Titans. Bilgirám is a place once considerable, and remarkable as the spot first fixed upon as the British advanced post, which was subsequently withdrawn to Kánhpúr (Cawnpore). Heber saw here the ruins of officers' houses, and what were once bells of arms.[4]

Bahráich, the chief town in Gonda-Bahráich, situated about 2 miles to the E. of the Sahti, an eastern branch of the Sarjú River, is celebrated as containing the shrine of Saiyid Sálár, who was killed in the beginning of the eleventh century, when fighting against the Hindús in the army of his maternal uncle, Mahmúd of Ghazní. It is remarkable that Hindús as well as Muslims make offerings at his shrine. The river here is a beautiful clear stream, winding as through a park. In many of the villages around the people are afflicted with the goitre. The Tarái Forest begins a few miles to the N. Bahráich has been a very populous town, but has greatly declined, and no part of Oudh has suffered so much from lawless violence as the districts surrounding it. Sándí, which gives its name to the *chaklá* so called, is stated by Heber to be a poor little village.[5] It is, however, remarkable for the noble mango groves that surround it, and for a fine lake on the south side, abounding in fish and covered with wild-fowl. The River Ghárá flows under the town to the north.[6] Near it is a very holy place called Brahmávast, situated on the lake to the south. The principal town in the *chaklá* is Sháhábád, which is a very large and ancient city, though Tennant in 1799 spoke of it as an expanse of ruins. But both Heber and Sleeman speak of it as populous; and the latter says it is inhabited by Patháns, who are a very turbulent race. The approach to the town is beautiful, from the rich crops which cover the ground up to the houses, and the fine groves and majestic single trees which surround it.

Inhabitants.

Though the extreme antiquity of the city of Awadh or Oudh, called in Sanskrit, Ayodhya, and the legend of the Rájpút princes, such as Rámah, who reigned there, appear to be incontrovertible evidence that the Aryan race bore sway in Oudh from a very remote period, there is proof as irrefragable that still earlier aboriginal tribes preceded the Aryan race in the possession of the country, and attained many centuries back to some degree of civilization. The following passage from Sleeman's *Journal*,[7] refers to one of the most important of these aboriginal tribes, called Bhars, and into it is compressed almost all that is known regarding them:—"Passed over some more sites of Bhar towns. The Oudh territory abounds with these sites, but nothing seems to be known of the history of the people to whom they belonged. They seem to have been systematically extirpated by the Mohammedan conquerors in the early part of the fourteenth century. All their towns seem to have been built of burnt brick, while none of the towns of the present day are so. There are numerous wells still in use, which were formed by them of the finest burnt brick and cement; and the people tell me that others of the same kind are frequently discovered in ploughing over fields. I have heard of no arms, coins, or utensils peculiar to them having been discovered, though copper *sanads*, or deeds of grant from the rajahs of Kanoj, to other people in Oudh, 600 years ago, have been found. The Bhars must have formed town and village communities in this country at a very remote period, and have been a civilized people, though they have not left a name, date, or legend, inscribed upon any monument. Brick ruins of forts, houses, and wells, are the only relics to be found of these people. Some few of the caste are still found in the humblest grade of society, as cultivators, police-officers, &c., in Oudh and other districts north of the Ganges. Up to the end of the thirteenth century their sovereignty certainly extended over what are now called the Bainswárá and Bansda districts; and Sultánpúr, under some other name, appears to have been their capital. It was taken and destroyed early in the fourteenth century by Alláhu'd-Dín, Sultán of Delhi, or by one of his generals, and named Sultánpúr. Chándúr was another great town of these Bhars. I am not aware of any temples having been found to indicate their creed."

Another aboriginal tribe are the *Pásís* (Pausies) of whom there are supposed to be about 100,000 families in Oudh. They are employed as village watchmen, but, with few exceptions, are thieves and robbers by hereditary profession, and many of them adopt poisoning as a trade. They form the worst part of the gangs of refractory chiefs, using the bow and arrow so expertly that they can send an arrow through a man at the distance of 100 yards. There is no species of theft or robbery in which they are not skilful, and they prosper as the disorders of the country increase. In the forces of any enterprising chief or bandit they serve without

Oude.

wages, for the sake of the booty to be acquired. But low as the caste of these miscreants is, they assume the name of rájpúts, when by murder and robbery they have acquired wealth and landed property. Then, by giving their daughters to rajpúts, they often get their pretensions to that proud name admitted. Thus Sleeman mentions that Gangá Baksh of Kásimganj is a Pásí, and his family, after acquiring landed possessions by the murder of the old proprietors, called themselves ráwats, and had their claims allowed.

Bráhmans and rájpúts are exceedingly numerous in Oudh; and, according to Butter, the former out-number the latter throughout the province, though their arrival in it was of later date. Thus, it is said, that about the Christian era Trilok Chand, a chief of the Bais rájpúts, came into Oudh from Ujjain, and that it was after his tribe had become settled that some Bráhmans immigrated from Kanauj. The Oudh Bráhmans have 22 sub-castes, of which the Misr, the Shukl, the Tiwárí, the Dúbe, the Pháthak, the Upádhya, and the Chaube are the principal. The Misr has 28 sub-divisions,[1] the Shukl 14, the Tiwárí 23, the Dúbe 14, the Pháthak 15, the Upádhya 5, and the Chaube 3. Sleeman[2] informs us that the Kanauj Bráhmans *condescend* to hold and drive their own ploughs, a thing which cannot be affirmed of any other family of Bráhmans in Oudh.

Of rájpúts, 29 tribes are enumerated, of which the most renowned are the Bais, Ráthúr, Hárá, Kachwá, Sombansí, Bisen, Solankhí, Bachgotí, Dichhit, Rájkumár, Chauhán, Janwár, and Sengar, or Sanger. Butter affirms that these tribes differ in name only, and all intermarry without restriction of family. There is no doubt, however, that this is a mistake, and that it is owing in part to the excessive restrictions upon contracting marriages with inferior tribes that the dreadful and almost universal practice of female infanticide is perpetuated. Sleeman was informed by the rájpúts themselves that this unnatural custom arose from the Muhammadan princes of Delhi, and other Muslim chiefs, demanding the daughters of rájpúts in marriage, and they, being too proud to comply and too weak to resist,[3] determined upon putting all their female infants to death. The same authority states that the Dhánkarís[4] and Sengars are the only exceptions to the rule which stigmatizes all rájpúts as murderers of their daughters; and that no rájpút can give his daughter to a rájpút whose tribe is a shade lower, though he can take a daughter from him. Thus the Sombansí cannot betroth their daughters to any but Ráthurs and Chauháns, and must give their whole property with them. The custom of destroying female infants has prevailed everywhere from the time of the first founders of their race, according to their own account, but this is extremely improbable. It is remarkable that the greater portion of the Ahban rájpúts have become Muslims. They still eat together with those who have not changed their creed, but from different dishes; and no member of the tribe ever forfeited his inheritance by changing his religion. They are very numerous in the northern part of Oudh, where, in Bharwárá alone they once possessed 989 villages, of which about one-tenth are now occupied. Loní Singh of Mithaulí, who sent in the English fugitives from Sítápúr to Lakhnau, is of this tribe.

Of the cultivating classes, the principal are the Kurmís, Lodhís, and Kachís. Muhammadans probably do not exceed one-eighth of the whole population of Oudh.

History and government.

As has been already stated, Oudh was one of the first provinces of India colonized from the West, and, according to Buchanan, this settlement took place 1366 years B.C. The same authority places the reign of Ramachandra, the son of Dasharathah, about 775 B.C. The Hindú legends, however, assign as the epoch of this prince, the conqueror of Ceylon, the conclusion of the Treta Yug, or Second Age. The kingdom of Oudh was then called Koshalah, and its capital Ayodhyah; and it is remarkable that Kausham, a word of kindred etymology to Kushalah, was the name of the great and ancient city of Kanyakubja, or Kanauj, situated close to the junction of the Kálí Nadí with the Ganges, and the rájás of which, there is little doubt, at times bore sway over Oudh. This is the conjecture of Mr Elphinstone,[5] and it is confirmed partly by the etymological coincidence of the names, partly by the actual immigration of a numerous tribe of Bráhmans from Kanauj, who are still called by the name of their original country. After Rámah, the legendary conqueror of Ceylon, sixty princes reigned in Ayodhyah, but nothing is recorded of them. The Rámáyanah, or epic poem which relates the exploits of Rámah, is now assigned by Professor Wilson to 300 B.C. Ayodhyah is not mentioned in the Mahábháratah, the next epic poem of the Hindús, which dates 240 B.C.[6] With the exception of the immigration of Trilok Chand, the Rájpút prince, from Malwah into Oudh, about the commencement of the Christian era, there is little to be collected regarding Oudh until the Muhammadan invasion. It must be remembered, however, that hundreds of works exist in Hindú, Persian, and Urdú, on the history and antiquities of India, which have not only not been translated by Europeans, but have never even been read by them; and in these much that will throw light on the ancient annals of Oudh may yet be discovered.

Oude.

In his eighth invasion of India, Mahmúd of Ghazní, in 1018 A.D., marched through North India, and captured the city of Kanauj. There is good reason to think that a division of his army then invaded Oudh, for the shrine of Saiyid Sálár, his reputed nephew, who is said to have been killed fighting against the Hindús, is still the object of pilgrimage at Bahráich. However this may be, it is certain that in 1195 A.D., Muhammad Bakhtiyár Khilji, the general of Kutbu'd-Dín Aibak, Emperor of Delhi, conquered Oudh.[7] In 1279, Tigi, who was governor of Oudh for Ghiyásu'd-Dín Bulbun, was defeated by the rebellious governor of Bengal, and hanged by the enraged emperor over the gates of Awadh, as Ayodhyah began to be called. About 1304 A.D., Alláhu'd-Dín, Emperor of Delhi, took the capital of the Bhars in Southern Oudh, and having razed it, built on its site the present city of Sultánpúr. From 1400 to 1478, there was an independent kingdom of Júanpúr or Jaunpúr, the ruler of which had possession of Kanauj, and in 1452 even laid siege to Delhi, but was finally overthrown by the Emperor Bihlol. In 1528, Bábar's army, which he had sent to reduce Oudh, was there defeated by an Afghan chief named Bábán, whereupon Bábar threw a bridge over the Ganges, under the fire of his artillery, crossed into Oudh, and drove his opponents out of the province. He was compelled, however, to make a second campaign against Bábán who, when Bábar was retiring to Agra, made a fresh inroad into Oudh, and captured Lakhnau (Lucknow). After the death of Bábar, Bábán raised a fresh insurrection in Oudh against Humáyún, but was finally crushed by that prince. At the accession of Akbar in 1556, Jaunpúr, with its adjoining districts of Oudh and the Doáb, had again been erected into an independent kingdom, but in 1559 Akbar re-conquered it. From this time till the reign of Muhammad Sháh, and the commencement of the government of Sa'ádat 'Alí Khán, and the dynasty of which he was the founder, the princes of this dynasty, and the dates of their accession, are as follows:—

1. Sa'ádat 'Alí Khán 1720
2. Saffdar Jang, nephew and son-in-law of Sa'ádat 'Alí.. 1739
3. Shujá'u'd-Daulah, son of Saffdar Jang. 1756
4. Asafu'd-Daulah, son of Shujá'u'd-Daulah.... 1775
5. Vazír 'Alí, son of Asaf 1797
6. Sa'ádat 'Alí, the second brother of Shujá'u'd-Daulah. 1798
7. Gházíu'd-Dín Haidar, son of Sa'ádat 'Alí.... 1814
8. Nasíru'd-Dín Haidar, son of Gházíu'd-Dín 1827
9. Muhammad 'Alí Sháh, brother of Gházíu'd-Dín.... 1837
10. Amjad 'Alí Sháh, son of Muhammad 'Alí.. 1842
11. Wajíd 'Alí Sháh, son of Amjad 'Alí 1847

The origin of the Oudh family, and the character of the first three princes, have been grossly misrepresented by the historian Alexander Dow, who, having been refused the saltpetre farm of the Alláhábád districts by Shujá'u'd-Daulah, took this base method of gratifying his resentment.[8] His slanders, however, are completely refuted by the unanimous voice of all the contemporary native[9] authors, by the evidence of Mr George Forster of the Bengal civil service, a contemporary of Dow, and by the plain statement of facts to be found in Mill, Grant Duff, and other English writers. Dow imputes to Sa'ádat 'Ali, throughout his account of that chief's career, the vilest treachery to his emperor and his country; asserts that Nádir Sháh was invited to invade India by him and the Nizám; and introduces the conqueror upbraiding these two nobles as "ungrateful villains to their king and country," and spitting upon their beards.[10] He also speaks of Shujá'u'd-Daulah as "the infamous son of a still more infamous Persian pedlar enjoying the extensive province of Oudh as a reward for a series of uncommon villanies."[11]

These assertions have been largely credited and copied by writers of repute, but they are entirely without foundation. According to native authors of eminence, the royal family of Oudh are Saiyids, or descendants of the Prophet through the Imám Músa Kazim, and therefore of the noblest Arabian descent. Forster mentions[12] that, during his journey through Persia, he had an opportunity of conversing with some of the inhabitants of Naishápúr, "who bore indisputable testimony to the ancient rank of the family of Shujá'u'd-Daulah." Naishápúr is one of the oldest cities in Khurásán,

and was for a long period during the ninth and tenth centuries after Christ the capital of that province. Here the ancestors of the Oudh family have, for a very long space of time, held landed possessions and ranked among the princes of the place. Mírza Nasír, one of this family, and the father of Sa'ádat Khán, the first núwáb of Oudh, came to Hindústán in the beginning of the reign of Bahádur Sháh, the second son of Aurangzíb. The emperor appointed him to a high office at 'Azímábád, where his tomb yet remains His second son Muhammad Amín was in Persia when Nasír died, and on being apprised of his father's decease, immediately set out for Hindústán, and was made by the Emperor Farrukhsiyar colonel of his body-guard.[1] Being a man of extraordinary personal courage and prowess, he soon rose to still higher distinctions, and was made governor of the fort of Agra. It was he who was the main instrument in delivering the Emperor Muhammad Sháh from the tyranny of the two Saiyids, who had already murdered his predecessor Farrukhsiyar. During a terrible *émeute* at Delhi, when the pusillanimous emperor hid himself in the seraglio, he rushed in, forced him from his retreat, made him mount an elephant, and cut a way for him, sword-in-hand, through a multitude of rebels. At the battle of Sháhpúr, in 1720, when Saiyid 'Abd'ullah was defeated and made prisoner, he greatly distinguished himself, and received the title of Sa'ádat Khán Burhánu'l Múlk, "the felicitous lord, establisher of the realm," by which name he was ever afterwards known. He was then appointed governor of Oudh, and reduced it from a state of anarchy to complete order, for which he was promoted to the rank of dároghah khás, with the titular command of 7000 horse. In 1736, Bájí Ráo, advancing to the Jamná, 40 miles south of Agra, ravaged the country far and near. Three of his generals—Mulhár Ráo Holkár, Pillají Jádav, and Wittojí Bole—committed great depredations in the Doáb, when Sa'ádat Khán, advancing from Oudh, overthrew their forces with great slaughter, and chased them for miles. He then moved on to Agra,[2] and took a prominent part in the subsequent operations against the Maráthas. In the meantime, Muhammad Mukím, nephew of Sa'ádat, came to India, and married his cousin, the daughter of Sa'ádat. He soon distinguished himself, and was ennobled by the title of Abú'l Mansúr Saffdar Jang, by which name he is afterwards known in history. In 1737, he, with the rájá of Kotah, commanded the rearguard of the Mughul army in that year's campaign against the Maráthas. Some years after, Nádir Sháh invaded India; and the calumnies of Dow respecting the treachery of Sa'ádat Khán, and his aid of the invader, are refuted by the unanimous testimony of the *Siyaru'l Mutaakhkhirín*, the *Nádir Námah*, the *Yádgár i Bahádurí*, the *Zafar Námah*, and all the histories of the time. Sa'ádat Khán advanced with an army of 30,000 men to the assistance of his own emperor Muhammad Sháh, fought a severe action with Nádir Sháh, was made prisoner, and shortly after died of cancer in the back. That his action with Nádir "was no concerted plan," as Dow pretends, was proved by the fact, that seven principal Persian leaders, and 2500 inferior officers and men, were killed, and upwards of 5000 wounded.[3] Sa'ádat received no token of favour from the conqueror; and when Nádir retired, Muhammad Sháh promoted Saffdar Jang to the government of his deceased uncle. The character of Sa'ádat is thus given in the *Siyaru'l Mutaakhkhirín*:—"He was excessively brave, chivalrous, and valiant; a man of great parts, thirsting after glory and renown, and of singular firmness and wisdom."

Saffdar Jang, together with the government of Oudh, had the appointment of *mír átish*, or commander of the artillery. In 1746 he was one of the chief leaders of the imperial army of Delhi that defeated Ahmad Sháh Durrání, and caused him to retire to Kábul. Next year Muhammad Sháh was succeeded on the throne of Delhi by Ahmad Sháh, his eldest son, who raised Saffdar Jang to the dignity of vazír of the empire. In 1753 a powerful conspiracy was formed against him, at the head of which was the viceroy of the Dakhan, Najíbu'd-Daulah, the chief of the Rohillahs, and the favourite eunuch. Saffdar Jang was compelled to resort to arms; laid siege to Delhi; and after an investment of the capital for six months, compelled the emperor to grant to him in perpetuity the provinces of Oudh and Alláhábád. The same year he died,[4] and was succeeded by his son Tilláhu'd-Dín Haidar, known to the English by his title of Shujá'u'd-Daulah, who is thus described by his enemy Dow:—"Shujá'u'd-Daulah is extremely handsome in his person; about 5 feet 11 inches in height; and so nervous and strong, that with one stroke of the sabre he can cut off the head of a buffalo. He is active, passionate, and ambitious, but his genius is too volatile for depth of thought; and he is consequently more fit for the manly exercises of the field than for deliberation in the closet. Till of late he gave little attention to business. He was up before the sun, mounted his horse, rushed into the forest, and hunted down tigers or deer till the noon of day. He then returned, plunged into the cold bath, and spent his afternoons among his women. He now spends more time at the comptoir of his finances than in dallying with the ladies of his seraglio. His authority, therefore, is established, his revenues increased, and his army on a respectable footing. But with all his splendid qualities, he is cruel, treacherous, unprincipled, and deceitful. If we except personal courage, he possesses not one virtue more than Saffdar Jang."[5] Such was the prince who was ere long to measure swords with the English. His first achievement was in 1756, when Dattají Sindhiyá,[6] advancing with a great Marátha army to conquer Rohilkhand, was encountered by him, and effectually checked. On this occasion, a division of the Maráthas, commanded by Govind Pant, was routed with great slaughter, and driven across the Jamná, in whose waters a great part of it perished.[7] After this the Maráthas made peace with the núwáb of Oudh, and marched off to attack Ahmád Sháh Durrání, a movement which resulted in their terrible overthrow at Pánipat.

In 1759, 'Alí Gauhar, eldest son of the Emperor 'Alamgír II., formed a league with Muhammad Kulí Khán, the súbahdár of Alláhábád, to invade Bengal, which was then governed by Mír J'afar, the ally of the British. They invited Shujá'u'd-Daulah to aid them in this enterprise, which he agreed to do; but no sooner had they marched than he, by stratagem, got possession of the fortress of Alláhábád, and soon after put to death Muhammad Kulí, who strangely enough returned and gave himself up. The English historians have not understood the true cause of this cruel action, but a perusal of the native writers will explain it. Muhammad Kulí was brother's son to Saffdar Jang, and of course heir-presumptive to Shujá'a. He had been appointed by Saffdar Jang to the command of Alláhábád, and had entirely withdrawn himself from the authority of the court of Oudh. A strong faction, at the head of which was Ism'aíl Khán of Kábul, had intrigued to put him in the place of Shujá'u'd-Daulah, who several times escaped with difficulty from their designs. The policy of an eastern prince in such cases is well known; and Shujá'a preferred to sacrifice his cousin rather than himself.

In 1760, 'Alamgír, having been murdered by his vazír, 'Alí Gauhar, was proclaimed emperor by the title of Sháh 'Alam, and his first step was to make Shujá'u'd-Daulah vazír on the 6th of January 1761. Shujá'u'd-Daulah commanded a division in the battle of Pánipat, and from that time became the most powerful prince in Hindústán. The Maráthas were crushed by their tremendous defeat, Muhammad Kulí was dead, Alláhábád re-incorporated with Oudh, and everything combined to encourage the vazír to encounter the British, an opportunity for which was not long wanting. On the 24th of May 1763 the city of Patna had been seized by Mr Ellis, a violent, unprincipled man, who was determined to force Mír Kásim, the núwáb of Bengal, into a war. A struggle accordingly commenced, and after severe fighting, Mír Kásim, defeated at all points, crossed into Oudh, and threw himself on the protection of Shujá'u'd-Daulah; who, with the Emperor Sháh 'Alam, was encamp ed at Alláhábád. Shujá'a espoused the cause of the fugitive núwáb; and, crossing the Ganges in the beginning of April 1764, laid siege to Patna, but was beaten off with loss. The mutinous conduct of the English troops delayed their operations for some time; but on the 23d of October 1764 Major Hector Munro came up with the Oudh army at Baksar, and after a severe action of five hours, put it to flight. The English loss was 101 Europeans and 773 Sipáhís killed and wounded, or more than one in nine of their whole army. Shujá'a had 2000 men killed, and lost 133 guns of all sizes. In its results, this battle was a second Plassy, as it left the English without a rival to their power, and compelled the Emperor Sháh 'Alam to throw himself on their protection; thus giving to their subsequent proceedings the colour of legitimate authority. Shujá'a now entered into negotiations with the English, but as he refused to surrender Mír Kásim, Sumroo, and the European deserters, operations in the field still continued; and a treaty was concluded with Sháh 'Alam, by which he ceded to the English Gházipúr and part of the territory of Balwant Singh, rájá of Banáras, while they agreed to put him in possession of all the dominions of Shujá'u'd-Daulah; but

[4] According to Forster and Grant Duff, in 1754. Mill gives 1753 as the year of his decease, Thornton 1756; but the authentic annals of the Oudh family, written in Persian, give 1166 A.H. = 1752–53.

[5] Dow, vol. ii., p. 394.

[6] Molesworth spells this name Shindá; the above is the Hindústání form of it, though Shakspeare makes it Sendhiyá.

[7] Grant Duff, vol. ii., p. 135. [8] Mill, vol. iii., p. 405.

the Court of Directors utterly disapproved and disallowed these terms, on the ground that extension of territory was impolitic and disadvantageous. Colonel Munro's army advanced from Banáras to the attack of Chunár, and after two unsuccessful assaults, returned to its quarters, but two battalions of natives occupied Lakhnau. Munro resigned in January 1765, and was succeeded by Major Fletcher, who, dividing his force, with one part of it reduced the Alláhábád districts; and with the other, commanded by Major Stibbert, captured the fort of Chunár.

Shujá'a now called in the Maráthas, who entered Oudh by Karha, and on the 3d of May 1765 were defeated near that place by General Carnac, and a second time near Akbarpúr, where, however, they plundered a great part of the English baggage. At the ford of Kalpí (Calpee) they again attempted to make a stand, but after a short action, were finally broken and dispersed. Shujá'a, with an appreciation of the English character which did him credit, now determined to throw himself on their generosity; and in August 1765 they concluded a peace with him, the principal conditions of which were, that he should pay L.500,000 towards the expenses of the war, surrender the fort of Chunár, not receive Kásim 'Alí or any deserters into his service, cede Karha and Alláhábád to Sháh 'Alam, levy no duties on any of the Company's merchandise throughout his dominions, pardon those of his subjects who had aided the English in the late war, and not molest Balwant Singh, their ally. He also covenanted to aid the English with his troops if their territories were invaded; and they, in return for all these advantages, agreed to furnish him assistance in case of a like necessity. It has been said that, from the battle of Baksar (Buxar), Oudh was a conquered country; and that the English having then given it to Shujá'u'd-Daulah, might be justified in resuming their gift if badly administered. But Oudh was never entirely subjugated, or even overrun; and the utmost that was ever proposed by the Bengal government was to make it over, when conquered, to Sháh 'Alam; a design that was bitterly censured by the Court of Directors. The words of Lord Clive are conclusive as to the motives of the treaty. He says[1]:—"Our restoring to Shujá'u'd-Daulah the whole of his dominions proceeds more from the desire of not extending the Company's territorial possessions, than the generous policy of attaching him for ever to our interests by gratitude, though this has been the apparent, and is by many thought to be the real, motive. Had we ambitiously attempted to retain the conquered country, experience *would soon have proved the impracticability of such a plan.*" Shujá'a, taught by his misfortunes, set to work to remedy his reverses with an energy and success which were proofs of a superior mind. In return for the districts ceded to him, the emperor granted to Shujá'a the hereditary possession of his dominions; and so well did the núwáb arrange his financial system, that in 1768 he had not only paid off all his debts, but possessed a full treasury and a flourishing revenue. He disbanded his irregulars and reduced the cavalry—which at the battle of Baksar amounted to 30,000, and had deserted him there without striking a blow—to 5000. With the help of some Frenchmen, he remodelled his army, raised ten disciplined battalions, and founded an arsenal at Faizábád. This progress aroused the jealousy of the English, who, in November 1768, imposed a new treaty on him which limited the number of his troops to 35,000 men, including irregulars. This restraint was exceedingly galling to the núwáb; and he henceforth viewed the English with distrust. However, in 1772 the Doáb and Rohilkhand were overrun by a powerful Marátha army under Sindhya, Holkar, and Hari Pant, who possessed themselves of all the territory belonging to Ahmad Khán Bangash, except the town and environs of Farrukhábád. Alarmed at this formidable invasion, the Rohillas besought Shujá'u'd-Daulah to procure the aid of an English brigade, and engaged to pay L.400,000 for its support. Shujá'a obtained the troops required, and the Maráthas were compelled to retire from their conquests; but the Rohillas then could not, or would not, make good their promise. And here occurs one of the blackest pages in the history of the núwábs of Oudh. Shujá'a was under obligations to the Rohillas, though there had been many passages of arms between them. They had sheltered his family in his misfortunes after the battle of Baksar, and had forborne to strike when he was unable to resist. It was therefore infamous to design their ruin,—a design which he now framed and accomplished with the aid of the English, who sold the liberties of this brave people to him for L.400,000. At the same time, Mr Hastings made over to Shujá'a, for L.500,000, the districts of Alláhábád and Karha, which belonged to the emperor, and had been solemnly assigned to him by the British themselves in return for an important service. The treaty was concluded in the end of 1773; and on the 17th of April 1774, Colonel Champion, with an English brigade accompanying the Oudh army, entered Rohilkhand. On the morning of the 23d a decisive battle was fought, in which the Rohillas were utterly broken, and their general, Háfiz Rahmat was slain.

After this dishonourable success, Shujá'a gave still stronger proofs of his callousness to generous sentiments in the cruel severity with which he treated the conquered Rohillas. It must be remembered, however, that, as a *Shí'ah* dealing with *Sunnís*, he had a religious incentive to rigour, similar to that which steeled the heart of the English Mary against her Protestant subjects, and made Philip II. deluge the Netherlands with blood. This fact has been wholly lost sight of by the English historians. It must be added that Sháh 'Alam had given his sanction to the conquest; that the English supported Shujá'a in all his proceedings; and that, as a mere question of policy, it was certainly for his interest to crush, and if possible extirpate, such warlike and dangerous neighbours as the Afgháns, who have given their name to Rohilkhand. He was yet busy with the arrangement of the conquered province, when a disease with which he was afflicted broke out so virulently that he was compelled to retire to Faizábád, where he died in January 1775, aged forty-six. He had received from his father a considerable principality, surrounded by implacable and powerful enemies; he left to his son an extensive and flourishing kingdom, secure from all aggression. Whatever his private character, he must be regarded as one of the ablest and most successful princes that have ruled in Hindústán. He was succeeded by Mírzá Arnání, his eldest legitimate son, who assumed the title of *Asafu'd-Daulah*, and who removed the royal residence to Lakhnau, then a mere village.[2] The Bengal Council, in opposition to the opinion of Mr Hastings, shamelessly seized this opportunity to extort immense sums from the young núwáb, and, to use the words of Mr Mill, "while they exacted all, and far more than had been covenanted by Shujá'a, from his son, declared their own engagements to be void by Shujá'a's death." They compelled Asaf, to raise the pay of the brigade which they had lent to his father, and which was no longer required in Oudh, to L.330,000 a year, and annexed territory bringing annually L.230,000. The first object of the new núwáb was to obtain from the emperor the office of vazír, which had been held by his father. This he secured in 1776, by sending at an opportune time 5000 men and some guns to the emperor's assistance. But this was the only gleam of sunshine during his reign, the history of which is that of a continual struggle with the exorbitant demands of the English. They drew from Oudh enormous sums, to supply which the wretched kingdom was parcelled out to farmers of revenue, who, as they grew powerful by draining the country of its wealth, gradually shook off their allegiance to the núwáb, and defied his authority. In addition to the brigade which, by the treaty of Faizábád, had been quartered on Shujá'a, a second, called the *temporary* brigade, was added in 1777, and several detached corps were from time to time imposed on the unfortunate Asaf, at an expense of L.120,000 a year more. Besides the Resident, who, by an agreement between Shujá'a and Mr Hastings, had been located in Oudh, another Company's agent was now added; and the expense of their establishments, and of the pensions, allowances, and gifts to various Company's officers, grew to that height, that no revenue, however elastic, could bear.[3] In 1779 the unfortunate núwáb petitioned for the removal of the troops quartered upon him, stating that they were "not only quite useless to his government, but, moreover, the cause of much loss, both in the revenues and customs, and that the detached bodies of troops, under their European officers, brought nothing but confusion into the affairs of his government, being entirely their own masters." But the exigencies of the governor-general were such that he was determined to force a supply of money from Oudh, in defiance of all reason and justice. The alleged debt to the English now amounted to L.1,400,000, and the salaries of the núwáb's own servants, and even of the members of the royal family, were deeply in arrears. Of the way in which this ruin had been caused a single specimen will suffice. Colonel Hannay,[4] a Company's officer greatly in debt, was foisted into the núwáb's service in 1778, as farmer of Bahráich and Gorakhpúr, and in 1781 had realized *a fortune of* L.300,000! On the 19th September 1781 Mr Hastings signed a new treaty with the núwáb at Chunár, by which he was relieved of the burdens which had been so unjustly imposed upon him, on condition of his plundering his grandmother, the Bahu Bígam, and his mother, of all their wealth, and sending it over to the English. This resulted in the famous spoliation of the Bígams, which formed the subject of the eloquent denunciations of Sheridan and Burke. A brief resumè of the question will be found in the pages of Mill and Wilson, the former of whom censures the conduct of Hastings in the strongest terms, while the latter inclines to defend him, but indirectly admits that the spolia-

tion of the royal ladies was a thing wholly at variance with the "easy temper" of the núwáb, and that he was driven to it by the insatiable demands of the English. For his part in the transaction, Mr Hastings accepted—that is, extorted—a *douceur* of L.100,000. The next step was to despoil Faiz'ulláh Khán, a Rohilla chief who had been suffered to remain in Rohilkhand by Shujá'u'd-Daulah, and who had brought his territory into the most flourishing state. It would, however, be impossible to condense into a short space the financial transactions of the English government with 'Asafu'd-Daulah. Suffice it to say, that from 1777 to 1786 the núwáb was compelled to pay the Company L.840,000 per annum, instead of L.330,000, which had been forced from him by the iniquitous treaty of 1775, and L.360,000 extorted by the still more iniquitous treaty of 1781. In addition to this, his country had been plundered by the gigantic frauds, briberies, and extortions of the Company's officers, as a sample of which may be taken the expenses of Major Palmer, the agent of Hastings, which alone were L.112,950,—L.22,800 being that gentleman's moderate annual salary.[1] Sir J. Macpherson and Lord Cornwallis alleviated this frightful oppression to some extent, but they only pruned and did not extirpate the evil; and in March 1797 Sir John Shore commenced new exactions, and imposed on the wretched núwáb the expense of two additional regiments of cavalry—one European, the other native. A few months after, Asafu'd-Daulah expired, leaving an impoverished country, a bankrupt treasury, and a dissatisfied people. He was a mild, easy, and somewhat indolent and sensual prince; but no abilities or virtues could have protected him against the relentless tyranny of the English government. He himself admitted that he had been rendered reckless and desperate by its insatiable demands. Mírzá 'Alí, the reputed son of Asaf, known to English writers as Vazír 'Alí, was now raised to the throne, and was publicly acknowledged by the English government. There was, however, a powerful faction against him; and Sir J. Shore hearing that he was a youth of impracticable temper, visited Lakhnau, and received proffers of vast sums if he would set him aside. "A large pecuniary sacrifice," says the governor-general, "was promised as a compensation for my acquiescence." Accordingly, on the 21st of January 1798, the núwáb was deposed, and Sa'ádat 'Alí II., brother of Asafu d-Daulah was raised to the throne on payment of L.120,000 in ready money, and on condition of raising the annual subsidy to the English to L.760,000, and paying all the expenses of the English armies in Oudh when exceeding 13,000 men. He further ceded the fortress of Alláhábád; and agreed to employ no Europeans, except Company's officers, in his service, nor permit them to settle in his dominions; to hold no communication with any foreign state; and to settle L.15,000 a year on the deposed Vazír 'Alí. The latter having been deprived of a kingdom on evidence upon which, to use the words of the historian Mill, "a court of English law would not have decided against him a question of a few pounds,"[2] was removed to Banáras. In 1799 it was resolved, in order to prevent any intrigues in his favour, to convey him to Calcutta; an intention which he bitterly resented. On the 14th of January in that year, he called on the Resident at Banáras, Mr Cherry, to complain; and on being chidden, rose from his chair and struck at him with his sword. His attendants immediately despatched the Resident and two other gentlemen; but on the arrival of a party of horse, took to flight. Having thus made his escape, Vazír 'Alí was soon joined by several thousand men, and maintained himself in rebellion for some time. He was at last traitorously given up to the English by a Rájpút chief, and carried to Calcutta, where he died a prisoner in Fort-William in 1817.

Sa'ádat 'Alí II. is represented by Sleeman at his first accession as a careless, jovial prince, fond of the chase and the glass. He was, nevertheless, so deeply impressed with the miserable condition of Oudh, and the impossibility of satisfying the demands of the English, that he at one time contemplated the abdication of his throne. Lord Wellesley, the then governor-general, eagerly grasped at this proposal, and used every stratagem and menace to secure the whole kingdom for the Company, but finding that Sa'ádat had no intention of trafficking away the birthright of his sons, and would not resign except in their favour, he compelled him to cede the richer half of his territories, including Etáwah, Karha, Farrukhábád, and the whole of Rohilkhand, 'Azímgarh, Gorakhpúr, Alláhábád, and many other districts, producing in all L.1,334,730 annually. The núwáb was further bound to dismiss all his regular troops, save five battalions of infantry, 2000 cavalry, and 300 artillerymen; the English government undertaking to defend the kingdom against all foreign aggression, and to coerce all rebellious subjects Of foreign aggression there never was the least probability; but when called upon to reduce rebellious chiefs, the English refused, or yielded a grudging compliance,[3] and in the succeeding reigns altogether refused to observe this condition of the treaty. The treaty was signed on the 14th of November 1801, and from that hour Sa'ádat 'Alí became a changed man. He gave up all the moderate pleasures to which he had been accustomed, and devoted himself heart and soul to the management of his kingdom. For the remaining fourteen years of his life few princes in ancient or modern times have displayed such self-denial and such attention to the business of their government as Sa'ádat. During his "salutary rule"[4] a great part of Oudh is described as "a magnificent garden."[5] By his prudence and economy he so reduced his expenditure within his income, that on his death, on the 12th of July 1824, he left fourteen millions sterling in a treasury which he found empty when he entered upon the government in 1797. He was a man of great general ability; had mixed much in the society of British officers in different parts of India; had been well trained to habits of business, understood thoroughly the character, institutions, and requirements of his people; and, above all, was a sound judge of the relative merits and capacities of the men from whom he had selected his officers, and a vigilant supervisor of their actions. He had a thorough knowledge of the rights and duties of his officers and subjects, and a strong will to secure the one and enforce the other.[6] Yet this was the man that Lord Wellesley would have put aside as worthless and incapable.

Sa'ádat 'Alí II. was succeeded by his second son, styled Ghâzíu'd-Dín Haidar. Shamsu'd-Daulah, the eldest son[7] of Sa'ádat, died before his father, and left a son; but he, according to the Muhammadan law, was excluded from the succession by his father's death in his grandfather's lifetime. Gházíu'd-Dín was young and in possession of vast wealth: he gave himself up to pleasure, and neglected the government. He was, besides, unfortunate in his selection of a minister—Aghá Mír, who was utterly dishonest, though a man of abilities. The young núwáb, immediately on his accession, gave to the minister L.500,000 to be expended in public works and charity. This Aghá Mír retained for himself, and forged letters to show that he had expended it as desired. Another million was borrowed by Lord Moira for the expenses of the Nepál war. The Resident, Major Baillie, was instructed to apply for the money, and "to make it appear as a voluntary offer on the part of the núwáb."[8] In March 1815 the Resident was instructed to apply for a second million, which he did in so disrespectful a manner that the núwáb, although he surrendered the money, insisted on his removal, and to this the governor-general assented; and on the 1st of May 1816 granted to the núwáb, in discharge for the millions just lent, an unproductive marshy forest called the Taráí, just taken from Nepál. This region became the sanctuary for all the rebels and banditti in Eastern Oudh, and there they built their strongholds. But money was not the only thing supplied by the núwáb to the English. In addition to the vast sums just mentioned, he mounted a whole regiment of English cavalry at his own expense, and supplied various necessaries towards the wars the Company were carrying on. In return for these services, and to sow jealousy between the courts of Delhi and Lakhnau, Lord Moira encouraged the núwáb to assume the title of King. Accordingly, in 1817, Gházíu'd-Dín for the first time coined money in his own name, and assumed the title of King in the year following. At the end of 1825, another "perpetual loan" of a million was borrowed from the king by the Company, the interest of which was to be paid to the minister, Aghá Mír, who, by a gross fraud, had obtained the king's consent. Next year another loan of half a million was obtained for, as it was said, two years. On the 20th of October 1827 Gházíu'd-Dín died, having expended, or rather given to the English, four millions of the fourteen bequeathed to him by his father. "He

[1] Mill, vol. v., p. 13, note.

[2] Ibid., p. 54. Wilson attempts to justify Sir J. Shore, and says many impartial witnesses were consulted; but, in the nature of things, there could have been no impartial witnesses at Lakhnau, and the judge himself, Sir J. Shore, was an interested party, for his government gained enormous sums by his decision. Moreover, the inquiry was private; and, if made at all, should have been made before the public acknowledgment by the English of Vazír 'Alí's legitimacy. There is no dispute that 'Asafu'd-Daulah acknowledged Vazír 'Alí as his son; and the troops and people were so much in his favour that there was a partial insurrection when he fled from Banáras. Wilson alleges that Sa'ádat had then become unpopular by his parsimony; but this is refuted by Sleeman, who says that Sa'ádat did not commence his economical reforms till 1801.

was an encourager of letters and the arts; was of a kind and conciliatory disposition, and afforded a not unfavourable specimen of an Asiatic prince[1];" but his ministers defrauded him of enormous sums,[2] and as he was prevented by treaty from keeping up sufficient troops of his own, and the British troops refused to act against refractory zamíndárs, that system of baronial aggrandizement commenced under his reign which has now made Oudh what England was during the worst period of the wars of the Roses. He was succeeded by his eldest son Sulaimán Jáh, who assumed the title of Nasíru'd-Dín Haidar. The treasury was full, and the young king "was anxious to spend his money in the manner best calculated to do good and please our government;" and Sir W. Sleeman has left it on record,[3] that had the English Resident given good advice, or even been willing to meet the king's advances, "Oudh might have been covered with useful public works." But the Residents for a long period of years made it their business to do nothing, or only interfered to extort vast sums of money, or to prefer the complaints of the Company's sipáhís, who were allowed privileges contrary to all justice and order. The object of the political officers employed in Oudh was, in plain words, to bring on such a state of affairs as should justify the annexation of the province. Nasíru'd-Dín, repelled by the Resident, gave himself over to sensual and intemperate habits, in which he had been encouraged from his early youth by his adopted mother, the Pádsháh Bígam, a woman of an ungovernable temper, but over-indulgent to her son. Among his first measures, the king attempted to make the fraudulent Aghá Mír disgorge the enormous sums of which he had robbed the state, but the British government threw their ægis over the traitor, and permitted him a safe retreat to Cawnpore, where he died in 1832. Some years before his death he set up a printing-press at Cawnpore, whence he disseminated attacks upon the Oudh government. His son took a leading part against the English in the mutiny at the above station, and held a high office under the infamous Náná Sáhib. Hakím Mahdí, who had been *ijárahdár*, or farmer, of Muhammadí (Mahomdee) and Khairábád from 1804 to 1819, and had made those districts a blooming garden, succeeded Aghá Mír[4] (after a brief interval, till February 1829, during which period Fazl 'Alí was minister), endeavoured to introduce reforms which would have restored Oudh to the condition in which it was under Sa'ádat 'Alí, but the king was immersed in sensual pleasures, and surrounded by vile courtiers and still viler Europeans, whose interest it was to prevent reform.[5] Hakím Mahdí was silenced, and even dismissed after two years' tenure of office,[6] and was succeeded by an imbecile old man, Roshanu'd-Daulah,[7] who was thwarted in everything by the king's unworthy favourites. Nasíru'd-Dín died, it is said by poison, on the night of the 7th of July 1837, and was succeeded by his uncle, Nasíru'd-Daulah, who assumed the title of Muhammad 'Alí Sháh. He was the third son of Sa'ádat 'Alí II., and, according to Muslim law, became heir to the throne, owing to the death, during his father's lifetime, of his elder brother Shamsu'd-Daulah, whose four sons were thereby excluded from the succession. Nasíru'd-Dín had left a son, Muna Ján, by a lady named Afzal Mahal, but had disowned him in order to gratify his resentment against the Pádsháh Bígam, whom, in later years, he detested, and who doted on the boy. The Bígam was not a person to suffer the rights of her favourite to be set aside without a struggle; and when Nasíru'd-Dín died, she marched to the palace with an armed multitude, and caused Muna Ján to be proclaimed king. The Resident, Colonel Low, however, suppressed the *émeute*, killing and wounding 120 of the Bígam's followers; and Muna, who was pronounced by the English government illegitimate,[8] was sent to Chunár. Muhammad 'Alí Sháh was a parsimonious and prudent old man, but in his short reign, till the 16th of May 1842, he could not restore the treasures wasted by his predecessor, who had inherited L.10,000,000, and left but L.700,000. He bequeathed, however, L.788,000 to his second son Amjad 'Alí, who succeeded to the throne, to the exclusion of Mumtázu'd-Daulah, the son of his elder brother Asghar 'Alí,—Asghar having died during his father's lifetime. Amjad 'Alí[9] died on the 13th of February 1847, and left L.1,358,400, and this, as far as can be ascertained, was expended by Wajíd 'Alí, the ex-king of Oudh, before his deposition, which took place on the 1st of January 1856. Wajíd 'Alí is a good poet and an accomplished man of letters, but not a man of business, and before his accession the great barons had become altogether too powerful to be controlled. The royal revenue declined daily during his reign; but on the whole, the condition of Oudh was not deteriorating, and the barons drew ample and increasing revenues from their estates. They maintain to this day 100,000 armed followers, and have 400 forts of such strength, that one of them (that of Rudhamau) has lately successfully defied a whole division of British troops, and repulsed their attack, with the loss of a general and 120 men. It was for the English government to have reduced and destroyed these forts, and to have restored the king's power, or to have retired from the country and left him to fight his own battles. The latter course was the one recommended by Lord Dalhousie, who felt that by the treaty of 1837, made by the governor-general, Lord Auckland, who had full powers to conclude it, and acknowledged by succeeding governors-general, though not by the Court of Directors, the kings of Oudh could not be deposed for misgovernment. That treaty provided, that in case of serious internal disorders, the English should assume the administration in trust for the king, and restore it to him, or his successors, when matters were adjusted. In an evil hour, however, in spite of the remonstrances of the ablest Residents, Sir W. Sleeman and Colonel Low, and the protests of two of the most enlightened directors, the home government resolved on the unjust and impolitic step of annexing Oudh to the dominions of the Company. The announcement was received with indignation and astonishment throughout India, and more than one Indian prince declared publicly in open court, that no native potentate could now feel himself safe. Fanatical emissaries went abroad in all directions, calling on the population to rise against the Faringís; and in little more than a year from the annexation the terrible revolt of the Bengal army broke out. In Oudh the whole population rose against the English as one man, and although Lakhnau was stormed and taken for the third time on the 19th of March 1858, the whole country remained in arms against the English up to the time at which this article concludes, in July of the same year. (See NORTH-WESTERN PROVINCES.) (E. B. E.)

OUDINOT, NICOLAS-CHARLES, Duke of Reggio and Marshal of France, was the son of a merchant, and was born in 1767. He was a soldier from his youth, and at the outbreak of the Revolution he was appointed to the command of a battalion. His skill and intrepidity speedily raised him in the scale of promotion. A successful stand which he made at the head of the regiment of Picardy against an overwhelming force of Austrians, gained for him in 1794 the rank of general of a brigade. His services under Moreau in Germany were recognised by his being created a general of division in 1799. Nor was his conduct less notable when, immediately afterwards, he was transferred to the army of Italy. Under Massena he played an important part in the victory of Zurich; in the famous defence of Genoa, under Brune, he distinguished himself at the passage of the Mincio; and his reward for these services was a sword of honour from the First Consul. The next important achievements of Oudinot were performed under the direct command of Napoleon himself. At the capture of Vienna he was the first to lead his corps into the city; on the memorable day of Friedland he elicited the commendation of Bonaparte himself; and on the field of Wagram he won a marshal's baton, a pension, and the title of Duke of Reggio. The warlike renown of Oudinot had now reached its climax. Although he conducted himself bravely in the campaigns of 1812, 1813, and 1814, his cause wanted that success which renders great exploits recognisable. On the first abdication of Napoleon he submitted to the Bourbons, and forsook for ever the fortunes of his great leader. The remaining years of his life, though occupied with the discharge of several high military offices, were spent in comparative inaction. His death took place in September 1847.

OUGHTRED, WILLIAM, an eminent mathematician, was born at Eton in 1573, and educated in the school there, whence he was elected to King's College, Cambridge, of which he afterwards became fellow. Being admitted to holy orders, he left the university about the year 1603, and was presented to the rectory of Aldbury, near Guildford in

Surrey; and about the year 1628 he was appointed by the Earl of Arundel to instruct his son in the mathematics. He kept a correspondence by letter with some of the most eminent scholars of his time on mathematical subjects; and his house was generally full of young gentlemen who came from all parts to receive his instruction. It is said that, upon hearing the news of the vote at Westminster for the restoration of Charles the II., he expired in a sudden transport of joy, at the age of eighty-eight. He wrote *Clavis Mathematica* in 1631; a Description of the Double Horizontal Dial in 1633; and *Opuscula Mathematica* in 1676. (See *Biographia Britannica.*)

OUGLITSCH, or UGLITSCH, a town of European Russia, government of Jaroslav, on both sides of the Volga, 63 miles W. of Jaroslav. The streets are narrow and irregular, and the houses ill-built. It has an ancient citadel, and is partially fortified. The churches are numerous; and there are two convents. Weaving and paper-making are the chief manufactures; and some trade in corn and Russian leather is carried on. Ouglitsch is an ancient town, and was once a place of great importance; but having been taken and burnt by the Poles, it has never regained its former prosperity. Pop. 7483.

OUNDLE, a market-town of England, county of Northampton, stands on the slope of a hill, nearly surrounded by the Nen, 24 miles N.E. of Northampton, and 78 N. by W. of London. The three principal streets are straight, well-paved, and lined with good stone houses. The town-hall and the parish church are the chief buildings; the latter being a large edifice in the early English style, with a hexagonal spire 200 feet high. There are several other churches, three schools, almshouses, and a savings-bank. In the vicinity is the site of Fotheringhay Castle, of which one large stone is all that remains. Pop. (1851) 2689.

OURG, or OORGA, a town of Mongolia, on the right bank of the Tula, 165 miles S.S.E. of Kiachta, and 720 N.W. of Pekin. The houses are generally built of wood; and the streets are so narrow as hardly to allow two men on horseback to pass. There are numerous temples, and a college for priests, who form a great part of the inhabitants. Pop. estimated at 7000.

OURO PRETO, formerly called *Villa Rica*, a town of Brazil, capital of the province of Minas Geraes, is built on a tract of uneven ground in the midst of lofty and barren mountains that abound in gold, 190 miles N.N.W. of Rio de Janeiro. Although it looks well from a distance, the streets are narrow, ill-paved, and irregular, and the houses have no appearance of uniformity. Of its six churches, one or two are fine buildings; the governor's palace is a large and well-built edifice of a square form; and there are also a town-house, barracks, treasury, and theatre. The educational establishments consist of a college, school of agriculture, and other schools; botanic garden, and public library. The town has declined very much in consequence of the gold mines becoming exhausted. These, however, are still worked by English companies; and an active trade is carried on with Rio de Janeiro. Pop. 10,000.

OUSE, a river of England, county of York, is formed by the junction of the Swale and the Ure, which unite near Borough Bridge. It flows through the great plain of Yorkshire, at first S.E. as far as the town of York, which it passes, and then pursues an irregular course S. and S.E., until it joins with the Trent to form the estuary of the Humber, by which it discharges its waters into the German Ocean. It receives the Nidd, the Wharfe, and the Don, from the left, and the Derwent from the right. Its whole length is about 60 miles; and it is navigable for large vessels up to York, 45 miles from its mouth.

OUSE, *Great*, another river of England, rises near Brackley, Northamptonshire, and flows in a very winding course, dividing for a short distance the counties of Oxford and Buckingham, and flowing in succession through Buckingham, Bedford, Huntingdon, Cambridge, and Norfolk, until it falls into the Wash, after a course of 160 miles, about two-thirds of which is navigable. It is the most meandering of English rivers, and the one that traverses the greatest extent of level country. The towns of Buckingham, Bedford, Huntingdon, and Ely, are on its banks. Its principal tributaries are the Old Nen, Cam, Little Ouse, Stoke, and Nar.

OUSE, *Little*, an affluent of the preceding river, rises in Suffolk, and flows N.W. till it joins the Great Ouse on the borders of Cambridge and Norfolk.

OUTLAW, is a term applied to one who flees from justice, or who wilfully neglects or refuses to appear and answer for a transgression in obedience to the process of a competent court. The punishment consequent on such contumacy is termed *outlawry*, and consists in an exclusion from the benefits and protection of the law, thus disqualifying the defendant from maintaining any action real or personal. From the Conquest until nearly the reign of Mary, an outlaw might be lawfully killed like a wild beast by any one who met him. This was especially the case if he resisted seizure; "but when once taken," says Bracton (iii. c. 14), "his life and death were in the king's hands; and if any man then killed him, he must answer for it, as in the case of any other homicide." Sufficient notice of the process of the court, and satisfactory evidence of his disobedience, is essential before a person can be outlawed. As a security for making the defendant aware of the process of court, three successive writs of *capias* are issued against him, and failing his appearance, a writ of *exigent*, requiring the sheriff to call him in five successive courts, is then sued out; and if he does not render himself up at the fifth call, judgment of outlawry is at once pronounced against him. At the same time that the exigent is issued, moreover, it is provided, as an additional security, that the sheriff shall make three proclamations of the defendant in notorious places in the county of his residence a month before the sentence of outlawry. In the case of contumacy on prosecutions for civil actions and inferior crimes, only one writ of *capias* is necessary before the exigent is awarded. Outlawry entails the forfeiture of the goods and chattels of the outlaw. It was formerly necessary for the outlaw to be restored to his law by the crown; but in modern times it is usual for the courts to reverse outlawries upon motion.

OVADA, a town of the kingdom of Sardinia, division of Alessandria, stands on the Orba, 9 miles S.W. of Acqui, and 20 S. of Alessandria. For the most part it is well built; and contains several churches, convents, schools, and hospitals, and a theatre. One of the churches is a handsome building. Manufactures of cloth, vermicelli, hardware, and silk, are carried on; and there is some trade in wine and silk. Pop. 6177.

OVAR, a town of Portugal, province of Beira, stands near the mouth of a river of the same name, 15 miles N. of Aveiro, and 22 S. of Oporto. It is well built, but unhealthy; and consists of one long street, well paved and clean. There is a harbour and a mole. The inhabitants are engaged in fishing, and carry on some trade. Pop. 10,500.

OVATION (*ovatio*) was a lesser triumph allowed to Roman commanders for victories won without the effusion of much blood, or for defeating a mean and inconsiderable enemy. The show generally began at the Alban Mountain, whence the general with his retinue made his entry into the city on foot, with many flutes or pipes sounding in concert as he passed along, and wearing a garland of myrtle as a token of peace. The term *ovation*, according to Servius, is derived from *ovis*, a sheep, because on this occasion the conqueror sacrificed a sheep, as in a triumph he

sacrificed a bull. Festus, however, derives it from *ovo*, "I exult," "I cry O!" while Dionysius maintains it to be a corruption of the Greek bacchanalian εὐοῖ. The senate, knights, and principal plebeians assisted at the procession, which concluded at the Capitol, where rams were sacrificed to Jupiter. The first ovation was granted to Publius Postumius Tubertus, for his victory over the Sabines in the 253d year of Rome. (Pliny, *Hist. Nat.* xv. 29.)

OVERALL, John, an English bishop of some celebrity during his day, was born in 1559. He was elected a scholar of St John's College, Cambridge, but afterwards removed to Trinity, of which he became a fellow. In 1596 he was made regius professor of divinity, when he took his degree of Doctor, and about the same time was elected master of Catherine Hall. In 1601 he was promoted to the deanery of St Paul's, London, by the recommendation of his patron, Sir Fulke Greville, and Queen Elizabeth; and in the beginning of King James's reign he was chosen prolocutor of the lower House of Convocation. In 1612 he was appointed one of the first governors of the Charter-House Hospital, then just founded by Mr Thomas Sutton. In April 1614 he was made bishop of Litchfield and Coventry; and in 1618 he was translated to Norwich, where he died in May 1619, at the age of about sixty. He was buried in that cathedral, where he lay unnoticed and forgotten till some years after the restoration of Charles II., when Cosin, Bishop of Durham, who had been his secretary, erected a monument, with a Latin inscription in which he is said to be "Vir undequaque doctissimus, et omni encomio major."

Wood observes, that he had the character of being the best scholastic divine in England; and Cosin, who perhaps may be thought to rival him in that sort of learning, calls himself his scholar, and declares that he derived all his knowledge from the good bishop. Overall cultivated a particular friendship with Gerard Vossius and Grotius, and some of his letters to those learned men are printed in the *Epistolæ Præstantium Virorum*. The bishop is known in England chiefly by his *Convocation Book*, 1606, *Concerning the Government of God's Catholic Church and the Kingdoms of the Whole World*, 4to, London, 1690; reprinted at Oxford in 1844; in which the author discusses the rights of civil and ecclesiastical governors. This work was solemnly approved by the convocations of Canterbury and York, and was afterwards published by Archbishop Sancroft, but it led to a stir he did not contemplate. (See Macaulay's *History of England*, vol. iv.)

OVERBURY, Sir Thomas, an English courtier, famous for his genius and the tragical history of his life, was the son of Nicholas Overbury of Boorton-on-the-Hill in Gloucestershire, and was born in 1581 at Compton Scorfen, the Warwickshire seat of his maternal grandfather. The early part of his career was one continued course of success. Having enrolled as a gentleman commoner of Queen's College, Oxford, he distinguished himself in philosophy and logic, took the degree of Bachelor-of-Arts in 1598, and came out into the world adorned with every scholar-like accomplishment. On his removal to London for the purpose of studying law in the Middle Temple, he found favour with the lord treasurer, Sir Robert Cecil, and a prospect of court preferment seemed to be opening up before him. The sudden disappointment of these hopes, by driving him to travel, was only the means of securing his ultimate success. He sojourned in different places both at home and abroad, acquiring foreign languages, inspecting foreign governments, liberalizing his manners and opinions, and marking those varied phases of life which he afterwards described with such fidelity and wit in his book of *Characters*. After his return to court, his polished bearing, polite attainments, and large experience, recommended him to the friendship of Robert Carr, an acquaintance to whom he had been introduced shortly before in Edinburgh, and who was now the rising favourite of James I. The travelled and accomplished scholar soon became the bosom confidant and indispensable oracle of the illiterate minion. He dictated his love epistles, supplied him with opinions and plans of action, took charge of all his secrets, and with absolute sway ruled the will that ruled the king. The result was, that those who wished to honour and propitiate the favourite, honoured and propitiated the favourite's master. James I. made him a knight in 1608; the court poets, with Ben Jonson at their head, ascribed to him every attainment and every virtue under heaven; statesmen craved his counsel; and princes sought his society.

Sir Thomas Overbury had now climbed to the pinnacle of power, and, like most other successful aspirants, he was seized with a giddiness which suddenly brought him down headlong. His imperious pride could not brook the thought that any one should be a fellow sharer with him in the affection of Carr, now Viscount Rochester. Therefore, although his conscience had not prevented him from writing the letters and sentimental ditties which had won for his friend the unlawful love of the profligate Countess of Essex, yet no sooner was it proposed to close this intrigue by marriage than he took the most decided measures of opposition. He exhorted Carr, by all his hopes of continued prosperity, not to take such a step; he wrote the famous poem called *The Wife*, for the express purpose of showing him the contrast between a chaste and an immodest spouse; and in express terms he denounced the countess as "a strumpet, and her mother and brother as bawds." It was this interference, and especially the epithets of infamy, that determined his fate. The countess planned a scheme of deadly vengeance; her infatuated lover Rochester, who feared the divulging of the secrets intrusted to his confidant, and her uncle the Earl of Northampton, who aspired to step into the doomed courtier's place, became her accomplices; and it is even said that the king, highly offended at the arrogant bearing of his minion's friend, was privy to the plot. In April 1613, accordingly, Overbury was offered a foreign ambassadorship; by the advice of Rochester he was induced to decline it; and on the 21st of the same month he was apprehended on the charge of disobeying the king's commands, and conveyed a close prisoner to the Tower. The victim was now in the clutches of his murderers, and was destined to expiate his offence by a death of aggravated and protracted pain. He was consigned to a dismal dungeon; his condition was deceitfully kept secret from his friends; not even a priest was allowed access to him; and a ruffian named Weston, who had been hired expressly on account of his knowledge of drugs, was appointed to be sole attendant. Then a process of slow poisoning was commenced. The daily food of the unconscious prisoner was tainted with deadly powders; the very water that he drank was poisoned, and inflamed the ever-burning thirst it was intended to allay; for three months and six days his strong constitution continued to be racked and wasted under the combined action of different drugs; and on the 15th September 1613, when he had become a mere skeleton, covered with a mass of sores, a clyster put an end to his life. The murderers, although successful at first in concealing their guilt, and although favoured by certain unaccountable circumstances connected with the deed, were at length, after the lapse of two years, overtaken by retribution. They were all tried and condemned. The four under-assassins, including Weston, suffered the penalty of the law; and Carr and his wife, now the Earl and Countess of Somerset, although pardoned by the king, were afterwards punished, the former by the loss of the royal favour, the latter by a most painful and loathsome death.

The tragical fate of Sir Thomas Overbury drew atten-

tion to his works, which were not published till after his death. His poem of *The Wife*, though over-elaborated and stiff both in thought and in diction, passed through sixteen editions before 1653, called forth numerous imitators, and is still valuable on account of its discriminating knowledge of human life, and its profound and high-toned moral sentiments. His other principal work, the *Characters*, was also admired for the happy and ingenious conceits, and the graphic delineations, which it occasionally displays amid its crowd of over-strained witticisms and unnecessary details. An incomplete edition of Overbury's productions, under the title of his *Miscellaneous Works*, was published in London in 1632, and was frequently reprinted. The latest and best edition is that published in the *Library of Old Authors*, accompanied with a Life of Overbury by Rimbault, London, 1856.

OVERFLAKKEE, an island of Holland, in the province of South Holland, formed by two branches of the Meuse,—the Haringvliet on the N., and the Volkerak on the S.,—and is bounded on the W. by the North Sea. A part of the island, called Goedereede, was formerly separated from Overflakkee by a branch of the river, but this has been dammed up, and the two islands united. The soil is fertile, producing wheat, barley, potatoes, &c. Length, 25 miles; greatest breadth, 7 miles. Pop. 17,000.

OVERTON, a parliamentary borough of N. Wales, county of Flint, stands in the midst of beautiful scenery on the left bank of the Dee, here crossed by a fine stone bridge, 14 miles S. of Chester, and 21 S.S.E. of Flint. It is a neat and generally well-built place; and has a fine old church, with some yews of great size and beauty in the churchyard. The people live by agriculture, and no manufacture or trade is carried on. Overton unites with Flint and other boroughs in returning a member to Parliament. Pop. (1851) 1479.

OVERTURE (Fr. *Ouverture*), a piece of instrumental music which precedes the opera, the pantomime, the cantata, &c.; and named *Sinfonia* by the Italians. The overture originated in France, and received a settled form from Lulli in particular. The opera overture has now no settled form, but is moulded according to the fancy of the composer. In the latter part of the last century overtures for concert-rooms and theatres were introduced. Among the composers of these were Stamitz, Abel, Lord Kelly (a Scotchman), Vanhall, Haydn, Pleyel. This kind of overture was, in fact, the early form of the symphony, afterwards developed by Haydn, Mozart, and Beethoven. Some writers think that the overture to an opera ought to consist of a sort of analysis of the opera itself; but the Spaniard Don Tomas de Yriarte, in his poem *La Musica*, very properly dissents from that opinion, and considers opera overtures so constructed as

"Diligencia pueril que en vano ostentan;
Porque la imitacion no causa agrado,
Si antes non se conoce lo imitado." (Canto iv., § 6.)

(G. F. G.)

OVERYSSEL, a province of Holland, bounded on the N. by those of Friesland and Drenthe, E. by Hanover and Rhenish Prussia, S. by the province of Gelderland, and W. by Gelderland and the Zuider Zee. Length, from N.W. to S.E., about 60 miles; breadth, 27 miles; area, 1282 square miles. It is entirely low and flat, with few hills and no mountains. The principal river is the Yssel, which separates it from Gelderland, and falls into the Zuider Zee below Kampen. The province is also watered by the Vecht and its tributaries; but none of these is of any importance. With the exception of a tract of rich clayey soil along the Yssel, the surface consists of wet and marshy ground, or of sandy and barren heaths. There are several lakes, but not of any size. The climate is damp, and not very salubrious. Wheat, barley, rye, buckwheat, pulse, potatoes, and fruits, are raised in the more fertile regions; but the inhabitants depend for their subsistence mainly on the rearing of cattle and digging of peat. The pastures are good, especially in the west; and horses, oxen, and sheep are bred. Bees are likewise a source of much profit, and fishing forms a lucrative employment. The chief manufactures are linen, woollen, and cotton fabrics; calico, damask, paper, &c. Spinning, bleaching, dyeing, and boat-building are also carried on. The capital is Zwolle; and among the other towns the chief are Deventer and Kampen. Pop. (1856) 233,723. (See HOLLAND.)

OVIDIUS NASO, PUBLIUS, in some respects the greatest poetical genius of Rome, was born at Sulmo, in the country of the Peligni, on the 20th of March B.C. 43. In that year Cicero was murdered, and on the very day of the poet's birth the consuls Hirtius and Pansa died in the campaign of Mutina. His father, a member of an old equestrian family, was only moderately wealthy. At an early age the poet and his brother Lucius, who was exactly a year older than he, were sent to Rome to be educated for the bar. Though placed under the first teachers of eloquence of that age, Arellius Fuscus and Portius Latro, the poet never took kindly to the study of oratory. His tendencies were all to literature, and especially to poetry. His father, with whom poetry was only a synonyme for poverty, warned him, but in vain, against his favourite pursuit. The death of his elder brother Lucius placed him in circumstances of moderate affluence, and from that time he was allowed to follow out his tastes pretty much as he chose. After completing his education, and mastering the Greek tongue at Athens, he travelled with the poet Macer in Asia and Sicily. After spending nearly a year in the latter country, he returned to Rome. His delicate health and indolent temper disqualified him for active life. It does not appear that he ever practised at the bar. He sat for a short time as a judge in the court of the Triumviri Capitales, and afterwards of the Centumviri, besides acting occasionally as a judge. His chief pleasure, however, was in the literary society of the capital. Among his friends he counted such men as Bassus, Ponticus, Propertius, and Macer. Virgil he only saw once. Horace, who was twenty-two years his senior, he often met. His intimacy with Tibullus was fast ripening into friendship when that poet was prematurely cut off. Unlike most of these literary friends, he owed nothing to the favour of Mæcenas. It is a significant fact that the name of that patron of letters does not occur once in all the poet's works. Ovid was three times married. His first wife proved unworthy of his choice, and was soon put away. His second was in like manner speedily divorced, though her chastity was, on the poet's own admission, beyond dispute. The real culprit in this case was the poet himself. Falling in with the fashion of the day,—a fashion which accorded only too well with his inclinations,—Ovid devoted himself to his mistress Corinna, and probably to other women. When about thirty years of age, he espoused his third wife, a member of the Fabian family. With her he lived happily till his exile, and by her he had his only child, his daughter Perilla. This daughter was twice married, and had a child by each husband. Not long after the birth of the first of these children, Ovid's father died, at the age of ninety. His mother survived her husband only a few months. They had lived to witness their son's rise and growing fame. They were spared the sight of his fall and banishment.

Ovid's life at Rome was on the whole a singularly fortunate and happy one. He had competent means, a house near the Capitol, a pleasant garden between the Flaminian and Clodian ways, a farm of some value in the country of the Peligni, access to the best literary society of Rome, and the favour of Augustus himself. His growing fame as a poet was justified by his three books of *Amores*, his

Epistolæ Heroidum, and his *Ars Amatoria*. The last of these works was published in B.C. 2, the year in which the elder Julia was sent into exile by her father. He had also completed, though he had not published, his *Metamorphoses* and his *Fasti*. He had submitted these, the most valuable and important of his works, to his literary friends, and was engaged in giving them the finishing touches, when he was overtaken by the great calamity of his life. In the year A.D. 8, he was banished from Rome. The place of his exile was Tomi, or, as he himself calls it, Tomis, an old Milesian colony on the shores of the Black Sea, near one of the mouths of the Danube. His sentence was a simple *relegatio*, and did not involve the loss of citizenship or the confiscation of his property. He has himself described with the most touching pathos (*Trist.* i. 3) the last night he was allowed to spend in Rome, and the pangs with which he tore himself for ever from his friends and family. The voyage to Tomi occupied the greater part of a year, and more than once the poet was in danger of his life from shipwreck. When at last he reached his destination, it almost seemed as if death would have been preferable. Tomi could hardly be said to be within the pale of civilization. The inhabitants were barbarous and ignorant, the soil barren, and the climate so cold that in winter even the wine froze. Savage hordes of Getæ from the northern banks of the river sometimes attacked the place, and rendered life itself insecure. It is hardly to be wondered at that in his petitions to be recalled, or at least transferred to some less utterly miserable place of exile, the poet should use the language of fulsome and even abject flattery to Augustus. But the emperor was inexorable; and neither the poet's own urgent prayers, nor the interest of his friends, availed to procure any mitigation of his sentence. He was left to drag out his remaining years, a prey to anxiety and despair, perhaps also to remorse. With his new townsmen he ingratiated himself by learning their language, and versifying their local legends and traditions. So popular did he make himself among them by these arts, that they passed a decree exempting him from all taxes. While his health allowed, he spent his time in putting the finishing touches to his *Fasti*, and in writing those letters to his wife and friends at Rome which we now possess in four books, under the title of *Letters from Pontus*. To this period of his life we also owe his *Ibis*, and the five books of the *Tristia*. It is from this last-named work that the events of the poet's life are chiefly known. Ovid died at Tomi A.D. 18, in the sixtieth year of his age and tenth of his exile.

Much has been written, and to little purpose, on the cause or causes of Ovid's banishment. The ostensible ground was the immoral tendency of many of his writings, especially his *Ars Amatoria*. But he confesses that this was a mere pretext, and hints obscurely at some "error" as the real cause of his punishment. What this "error" was, it is useless to conjecture; but we may conclude that it partook of the nature of a grave moral offence, as, on the poet's own admission, it deserved a severer punishment than even the very severe punishment it received. It was long a favourite theory with some scholars that the crime in question was an intrigue with the emperor's daughter Julia, the Corinna, as they maintain, of the *Amores*. A refutation of this view, however, is contained in the fact, that Julia was exiled ten years before her supposed paramour. A more plausible theory is that which alleges an intrigue between the poet and the younger Julia, the emperor's grand-daughter. It is a strong objection to this view that Ovid was old enough to be the younger Julia's father; but it receives a curious confirmation from the circumstance that they were both banished in the same year. The idea that he fell under the displeasure of the imperial family for his political views, is both at variance with his own statements, and is not sufficiently supported by historical evidence. The real cause was no doubt the "error" to which he himself alludes. What that "error" was, is, and is likely ever to be, a mystery.

The longest and most ambitious of Ovid's works is his *Metamorphoses*, in fifteen books. It is the only one of all his writings in which he does not use the elegiac metre. The mythologies of Greece and Rome furnished Ovid with the materials for this work, which comprises every, or nearly every legend and tradition involving, as the name implies, a transformation. The component parts are worked into a harmonious whole with rare skill; while many of the episodes are unrivalled in Latin literature for vigour of fancy, warmth of colouring, and simplicity and variety of diction. Next in importance to the *Metamorphoses* come the *Fasti*, in twelve books, six of which only have survived. This work is a kind of poetical Roman calendar, in which, beginning with January, he describes the rites and festivals peculiar to every day of every month, preserving every old story or interesting legend attached to each. As much of this work was drawn from the oral traditions current among the common people, and from ancient chronicles extant in his day, but long since lost, the *Fasti* form a valuable historical monument. It is inferior in general effect to the *Metamorphoses*, but is read with interest for the events it relates, and with pleasure for the real poetry with which these are set off. Of his minor works, the *Amores* and the *Ars Amandi* are notable for the deep knowledge of human nature, and especially of the female heart, which they display. The general tone of both is indefensibly immoral, and in many passages they breathe a warmth and even grossness of passion which nothing can excuse. The effect of such writings could not but have been dangerous to the morals of the people, and the danger is enhanced rather than diminished by the transparent veil under which the author affected to hide his voluptuous pictures. Even his *Epistolæ Heroidum*, a work still highly popular as a text-book for schools, is far from being quite free of these vices. In addition to the works already mentioned, Ovid wrote a tragedy entitled *Medea*, which is mentioned in terms of praise by Tacitus and Quinctilian. It has long since perished.

The memoirs of Ovid are numerous. The most careful and elaborate, though not the most correct, is that of Masson, originally published at Amsterdam in 1708, and frequently reprinted since that date. The most accurate and reliable, besides the most interesting, is the Life of the poet in Italian by Rosmini, Milan, 1821. Besides these there are numerous shorter sketches, of which may be specified the two old Latin biographies generally prefixed to the larger editions of Ovid's works, and those by Manutius, Paulus Marsius, and others, which are given collectively in Burman's edition.

The *editio princeps* of Ovid appeared at Bologna in 1471, and at Rome in the same year. The first Aldine edition was published in 1502. The Elzevir edition of Heinsius appeared at Leyden in 1629; and that *In usum Delphini* at Lyon in 1689. The best is that of Burman (see BURMAN, *Peter*), Amsterdam, 1727, which has not been superseded by the later French edition of J. A. Amar in Le Maire's *Bibliotheca Latina*, or by the German one of J. C. Jahn, Leipsic, 1828. The editions of the separate works are numerous, and some of them excellent. The translations of Ovid into the languages of modern Europe are very numerous. Of these we can only indicate here a few of the best that have appeared in English. The most admired is "Ovid's *Metamorphoses*, in fifteen books, translated by the most eminent hands," London, 1717. The "eminent hands" in question were Dryden, Addison, Congreve, Rowe, Gay, Phillips, Croxall, Sewell, and, Garth; the last of whom wrote the preface and saw the work through the press. This version has been frequently reprinted. The earliest English verse translation of the *Meta-*

morphoses is that of Arthur Golding, London, 1567. The first five books of the same work were "Englished in verse, mythologized, and represented in figures" by G. Sandys, Oxford, 1626. A blank-verse translation of the whole poem was published by Howard in London, 1807. The *Epistles* were rendered into English verse by several hands,—viz., Dryden, Otway, Settle, and others. This translation, which has been several times reprinted, appeared first in London in 1680, with a preface by Dryden. Of the literal prose translations may be mentioned that by Clarke, London, 1735; another which appeared in 1748; and that by H. T. Riley, published in 1851–2, forming 3 vols. of Bohn's Classical Library.

Ovid has always been highly popular in France; and the French translations of his various works are very numerous. A very complete list of these is appended to the article on Ovid in the *Biographie Universelle*, by M. Villenave. (J. C—L.)

OVIEDO, a province at the northern extremity of Spain, constituting the greater part of the principality of the Asturias, lying between 42. 57. and 43. 38. N. Lat., 4. 35. and 7. 4. W. Long. Its natural limits are so marked as not to have been much disturbed in the various governmental divisions; and its actual boundaries are,—N., Bay of Biscay; E., the province of Santander; S., Leon; W., Lugo. It is separated from Santander by the River Deva, and from Lugo by the River Eo. Its greatest length, from E. to W., is 147 miles; breadth, from N. to S., about 53; and its area, 3674 square miles. It has a coast-line of about 148 miles, from Rivadeo on the W., to Santiuste on the E., of extremely irregular outline, bristling with headlands, of which the most prominent are the Cabo de Peñas, de Torres, and San Lorenzo, and indented with creeks and estuaries, into which numerous streams descend, which being of little volume, and encountering a stormy sea, deposit dangerous bars. The chief of these estuaries are those of Navia, Pravia, Avilés, and Villaviciosa. Little has been done to improve the naturally bad harbours, of which the principal are those of Gijon, stretching 2 miles inland, from between Capes Torres and San Lorenzo; Ribadesella, with 10 feet of water on its bar; and Lastres. Jovellanos projected a harbour in the Bay of El Musel, near Gijon, protected by Cape Torres. There is no bar; the bottom is firm and level; and the execution of this project is most important for the development of the province. The surface of the country is extremely broken by two chains of mountains and their offshoots. A branch of the Pyrenees, formerly known as the Hervaseos, extending in an unbroken line parallel to the coast from Leitariegos to Peñamellera, forms the south rampart of the province, and sends off innumerable cordales, which form, at their junction with the main cordillera, deep and precipitous valleys, but broaden and diminish as they proceed, cultivated in terraces, or covered with oak and chestnut forest. The main chain is very lofty, rising in some parts to more than 10,000 feet, and presents a series of conical summits, covered with snow some months in the year, and generally loaded with the masses of vapour from the Atlantic which they arrest. Another chain of less elevation stretches from Pravia on the W., to Peñamellera on the E., where it joins the former; and the comparatively broad spaces between the cordales and the south declivities of this "cordillera of the coast" are the most fertile and delicious valleys of the Asturias,—traversed by numberless streams, covered with verdure, and very populous. Next the coast is an isolated group of mountains, from Buron westward, where offshoots descend into the sea. The principal rivers are the Nalon, Narcea, Navia, Piloña, Sella, and Eo. Nalon, which is the largest, rises in the pass of Tarna, flows N.W. 62 miles, and falls into the Bay of Biscay at Mures. Especially after its junction with the Narcea in Ambas Mestas, its waters abound with fish, salmon, lampreys, trout, and mullet; at its mouth are valuable salmon-fisheries. Narcea, also a good fishing stream, and for most of its course rapid, rises on the borders of Leon, receives the Nioron and the Pigueña, and joins the Nalon on its right at Pravia, after a course of 54 miles. The Navia rises in Lugo, and flows N.N.E. about 90 miles to the sea at Navia. The Piloña or Infiesto, from Peñamayor, joins the Sella at Las Arriondas, and falls into the sea at Ribadesella. The Eo, rising in Lugo, has a N.E. course of about 50 miles, and joins the sea at Rivadeo, in a beautiful bay famed for its salmon and its oysters. Communication with Galicia and Castile is possible only by the eighteen or twenty difficult passes of the south cordillera. The Camino Real along the coast from Santander to Ferrol is also extremely bad, broken, and impassable in winter, being almost quite unprovided with bridges; and the roads in the interior, with few exceptions, are proportionally wretched, seldom pretending to be anything more than rough bridle-paths.

In regard to geological structure, the province may be divided into three districts. Of the west part, between the rivers Eo, Navia, and Narcea, the base is transition or Cambrian rocks. The principal rocks are slate, trap, and quartz; among which are some thin beds of limestone which bear traces of very ancient exploration, and various groups of igneous formation—more frequently veins of oxide and carbonate of iron, and magnetic pyrites, to which class of Cambrian belongs also the Cabo de Peñas. The eastern part of the province, with the chain of hills from Leitariegos to Peñamellera, and its cordales, is of Silurian formation, limestone predominating, with occurrence of slate and quartzy rocks, over which the soil is thin and poor. This part presents the strikingly picturesque scenery peculiar to its formation, among the aspects of which may be mentioned the singular gulfs or subterranean passages of the mountain streams, and many caves of great extent, as that of Sequeros in the concejo of Tineo, adorned with beautiful stalactites. Among the valuable mineral products of this tract are building-stones, marbles, lithographic stones, and coloured marls; with veins of copper, cobalt, iron, calamine, antimony, argentiferous galena, and coal of an inferior quality. The centre of the province is carboniferous, abounding with organic remains; and its mineral products are coal, gypsum, salt from various springs, as of Sariego Muerto, and Sariego de Siero. There are extensive chalk deposits in the coasts of Gijon, Villaviciosa, and Colunga, and in the central concejos of Llanera, Siero, &c. Deposits of turf in Cudillero, Artedo, and other points, supply their population with fuel.

Agriculture is very backward, although, in spite of the unequal surface, the humidity, and the much ground occupied with sterile rock and sand, this province enjoys a climate and soil of rare excellence, as is proved by the variety and abundance of its products even in its neglected state. Wheat is not much grown, and the little is partly exported. An early indigenous variety, called *escanda*, is used. The staff of life is maize, made into a kind of bread called *borona*. Beans, pease, and potatoes are grown everywhere. Great quantities of rye and hay are grown in the poorer tracts. The fruits and legumes are excellent, especially the stone fruit of Candamo and the limestone tracts. From Llanes to Avilés, in the coast *concejos*, and in many districts of the interior, large quantities of apples are grown, from which cider is made,—the favourite beverage of the province. It is also exported to the neighbouring provinces and to Spanish America. The oak and chestnut forests supply bark for tanning, charcoal for the iron-works, and wood for construction. The hazel grows wild plentifully along the streams, and the nuts are exported to England from Gijon and Villaviciosa. In the small towns the cherry, fig, plum, pear, walnut, and chestnut are abundant.

Oviedo.

Along the whole coast the orange and lemon were grown when there was an export trade; their occurrence is now limited to the part between Llanes and Ribadesella. The growth of wine, general in the Asturias before the sixteenth century, is now confined to Candamo, Grado, Tineo, and some of the western districts. Among useful but less cared-for products, are the bilberry (used in dyeing leather), madder, kermes, hop, and saffron. In the large natural pastures are reared, by a system of migration, great quantities of horned cattle, sheep, and goats. The refuse of maize and acorns support many swine. The horses are small, but strong, sure, and active. The excessive division of property, and ignorance of good methods, combine to injure greatly the agricultural prosperity of the province; and though the cultivation, such as it is, has continued to push its way and reclaim useless ground, this has not always been done with prudence, and the effect has been in many cases, by loosening the exposed and precarious soil, to convert good though rough pasture into utter rock and barrenness. The wolf, fox, and hare are frequent; but the larger game—the bear, wild boar, deer, and mountain goat—have disappeared, and are only to be met with in the wildest parts of the S. cordillera. Partridges, quails, woodcocks, &c., are frequent.

The mineral industry of the province is the most important, but more so in prospect than in reality. Jovellanos was the first to direct public attention to the extent and value of the coal deposits, and much has been done since his time, though the want of native enterprise, of good harbours and roads, and the supineness of government, have been heavy drawbacks. Coal in great abundance and good quality is found chiefly at Langreo, Tudela, Santofirme, Mieres, Ferroñes, Lieres, Nava, and Torazo. The quantity extracted at Langreo in 1847 amounted to 5000 cwts. daily. At S. Maria del Mar, in Avilés, where are galleries under the sea-bottom, it is not so good. The whole amount extracted in 1847 was 473,000 cwts. Other minerals have been already indicated. Iron is found in many places, but is not worked to any extent, except in Castropól. Langreo, which, with iron, has all the necessary adjuncts of coal, water-power, and tolerable roads, is not taken advantage of. Copper is found at Po de Cabrales, Caldueño de Llanes, &c.; cinnabar to some extent at Mieres. The cobalt of Peñamellera, and the argentiferous lead of San Estévan de Leces, near Ribadesella, have been abandoned. The ancient tin mines at Salave are deserted. The principal manufactures are,—utensils of copper at Avilés; nails and iron instruments at Boal, La Vegiña, Coaña, Navia, Castropól, &c.; linens and damasks in Avilés (a house manufacture of coarse linens and quilts is carried on in all the rural districts); pottery at Ceceda, Faro, and Avilés; common delft at La Pola de Siero. In Oviedo and Gijon a good deal of beautiful cabinet-work is made with the walnut, cherry, yew, and other native woods. Fish are cured for export at Cudillero, Luanco, Candas, and Lastrés. Lard is made at Salas, Piloña, &c.; cheese at Cabrales. The commerce of the province has been sufficiently indicated. For internal trade there are fairs at Oviedo on Assumption Day, All Saints', and St Matthew's; at Gijon on St Ferdinand's and St Michael's; at Avilés on St Augustin's; at Villaviciosa on St John's; but they are much decayed.

The Asturian is strong, enduring, and laborious, of simple and primitive habits, and proverbial thrift. Many migrate yearly to the various provinces of Spain, particularly the wine-growing, where they become domestic servants, or engage in shop-keeping, &c., and having acquired a competence, return to their native hills. The dialect, called *bable*, is nearly identical with the ancient Castilian. Jovellanos endeavoured to enrich the literary language with ancient words, which it alone preserves, and to illustrate by it the progress of the national tongue and the changes of national manners. In this secluded region, among this hardy stock, an infinite number of primitive usages are preserved in weddings, games, funerals, and church ceremonies, of whose antiquity documentary evidence exists in the charters and municipal laws granted by the native princes, from Alonso VI. downwards. For a similar reason, the church architecture of the Asturias—the most ancient in Spain, perhaps in Europe—is interesting, giving a period of transition from the Roman to the later pointed Gothic or Tedesco. It has many points of resemblance with the early Saxon. Good specimens are the S. Maria de Naranco, the S. Miguel de Lino, and the S. Julian, at Oviedo.

The province of Oviedo (*Asturia Transmontana*) was first properly subdued by Publius Carisius under Augustus. The names of several towns, various inscriptions, and vestiges of mines, attest the Roman dominion. It was the last province in Spain to submit to the Goths. In the eighth century Pelayo took refuge there after the fatal battle of the Guadalete, and the Asturians maintained their independence under his descendants throughout the Moorish period. The Asturias was made a principality in 1388, and the title conferred by Don Juan I. on his son Enrique, in imitation of the title of Prince of Wales, when Enrique married Catharine, daughter of the Duke of Lancaster. Oviedo suffered much in the war of independence—the capital being twice plundered, once by Ney in May 1809, and afterwards by Bonnet. The Asturians are considered by Spanish writers to have done miracles in that war; but the only important step they took was to send the Conde de Toreno for assistance and money to London. There is a kind of Bœotian stigma on the Asturias; but they have produced many eminent men, of whom it will be sufficient to mention the name of Jovellanos, poet and patriot, worthy of a more grateful country. The province is divided into 15 partidos; and in 1849 had a population of 450,610.

OVIEDO, chief town of the preceding, is situated about 14 miles S. of Gijon and the coast, on a slope. About a mile to the N.W. is the Sierra de Naranco, 1070 feet above the sea, by which the town is protected from the N. winds, though the vapours collected by it in the spring and autumn render the climate extremely humid, and do not conduce to its salubrity. Most part of the town was burned in 1521, and the reconstruction, till within some years, has been irregular. The four main streets are formed by the roads connecting Gijon and Leon, N. and S., and Santander and Grado, E. and W., which cross each other in a central plaza. The streets are clean and well-lighted; the houses are built with projecting roofs. In the central plaza are the Casas Consistoriales, with a piazza,—the finest, it is said, in Spain. There are two prisons: one known as the Real Castillo—the fortress, with some changes, built by Alonso III., A.D. 913, on the west in an angle of the walls. It was partly destroyed with gunpowder by General Bonnet in 1818. The other is called the Carcel Galera. There is a theatre, capable of containing 700 spectators. The university, founded by Philip III. in 1604, after the project of Valdés, Archbishop of Seville, is a square building, 180 feet every way; the N. gate has two lofty Doric pillars on each side; the E. gate is more handsome. These entrances open on a central court with pillared galleries. The university has a library, founded in 1764, of 12,000 volumes; a museum of natural science, particularly mechanics and chemistry; and various theological and philosophical chairs. There is a normal school, three other public schools, and 17 private. The poor-house (*Hospicio Provincial*) is a large and handsome edifice, of date 1752. In 1837 the three hospitals of the town were consolidated into a general hospital in the ex-convent of San Francisco. The present cathedral was commenced in the fourteenth century, the previous church, erected in the ninth century, being taken down, and nothing is now left of it save the Camara Santa. The west front

has a fine portico of ornamented arches, with two lateral towers, of which the completed one rises 200 feet; the uncompleted tower was surmounted in 1575 with a pyramidal top. Of the lateral chapels, the most remarkable are the Capilla del Rey Casto (Alonso II.), where are the remains of many successive princes of the House of Pelayo; and the Camara Santa, containing in an arca the relics saved by Don Pelayo when he fled to the Asturias. Besides the cathedral, there are four parish churches and six convents in Oviedo. The churches remarkable for their early architectural style have been already mentioned. Outside the town, on the Gijon road, is a black marble monument to Jovellanos, re-erected in 1835. The industry of the town, and productions of the neighbouring country, have been indicated in the preceding article. Pop. (1847) 9384.

OVIEDO Y VALDEZ, Gonzalo Fernandez de, an early historian of the New World, was born at Madrid, of noble descent, in 1478. He was attached in his boyish years to the court of Ferdinand and Isabella as one of the pages of Prince John, where he received an excellent education. The discoveries of Columbus had just opened up the New World to Spanish enterprise; and in 1513 Oviedo was sent out to San Domingo as a supervisor of gold smeltings, where, except occasional visits to Spain and Spanish America, he remained during the rest of his life. In this position he is said to have treated the natives of the island with great cruelty, so that their gentle and feeble race rapidly melted away under the harsh servitude of the gold mines. In addition to his original appointment, Oviedo held several important offices under the Spanish government in Hayti. He had always exhibited a passion for writing; and the post of historiographer of the Indies to Charles V. was quite to his liking. Besides some inconsiderable chronicles of Ferdinand and Isabella, and of Charles V., and a Life of Cardinal Ximenes, he wrote two works of abiding interest and value: one was *La General y Natural Historia de las Indias Occidentales*, consisting of fifty books, of which twenty-one were published at Seville in 1535, while the rest remain still in manuscript. Several editions of this History have been published, of which the latest is that begun in 1851 by the Real Academia de la Historia, Madrid. It was translated into French by Poleur in 1556, and into English by Eden in 1555. This work contains a great mass of valuable information, thrown together in a crude, indigested state, and written in a loose, rambling, moralizing style, sadly provoking to the reader's patience. It is worthy of notice also, that his contemporary, the brave and philanthropic Las Casas, the defender of the American Indians, a man who had ample means of knowing about the affairs of the New World, denounces the History of Oviedo as "as full of lies almost as pages." The benevolent churchman and the courtly historian had separate interests, however, which kept up a constant hostility between them. Las Casas was doubtless much the nobler man of the two, but Oviedo was not therefore necessarily a wholesale fabricator. The other work for which Oviedo is still esteemed among scholars is *Las Quinquagenas*, written during the latter years of the author's life, and devoted to fond recollections of his native land, and of the principal characters who had figured there during his time. It consists of a series of immethodical dialogues, full of gossip and curious anecdote, drawn from the memory of a long life. It occupies three folios of MS. in the National Library of Madrid, but has never been printed. The author concludes by saying that it was finished on the 23d May 1556, when he was seventy-nine years old. He died at Valladolid during the following year. (See Ticknor's *Hist. of Spanish Literature*, vol. i., p. 514; and Prescott's *Ferdinand and Isabella*, vol. i., p. 187.)

OWEN, John, the eminent Puritan divine, was the son of Henry Owen, vicar of Stadham in Oxfordshire, where he was born some time in the year 1616. His biographers have traced his lineage backward to one of the five regal tribes in Wales; but we shall not here attempt to untwist the tangled knot of Welsh genealogies. He received his earlier education in the private academy of Edward Sylvester at Oxford, where the immortal Chillingworth had also been a pupil; and at the strangely precocious age of twelve entered as a student at Queen's College, having for his tutor Thomas Barlow, who was even then distinguished, and who subsequently rose to the see of Lincoln. He pursued his studies with an excess of application which would have destroyed most constitutions, and which left some seeds of future suffering even in his iron frame; for he allowed himself during many years only four hours for sleep, though the evils of this course were so far counteracted by his indulging in some of the most robust amusements of his college, and by the daily practice of music, in which he received lessons from Dr Thomas Wilson, the preceptor in the same delightful art of Charles I. Many years before the completion of his studies, Laud had been raised to the chancellorship of Oxford, and had begun to impose upon the students many of those rites and ceremonials which the Reformers had most severely condemned, the penalty of resistance to his demands being nothing less than expulsion from the university. All the worldly interests of Owen pointed to compliance with the innovations of this bigoted ecclesiastic; but convinced that very much of what Laud imposed was in itself wrong, and that what was in itself indifferent ought not to be complied with when sought to be bound upon the conscience as of Divine authority, and thus finding his way to the true standing-ground of the Puritans, he refused subjection to the innovations; and at the early age of twenty-one left Oxford, self-exiled for conscience sake. He found a home as chaplain and tutor, first in the family of Sir Robert Dormer, and subsequently in that of Lord Lovelace in Berkshire; but meanwhile the unconstitutional measures of Charles had driven the Parliament to arms, and placed the country in a state in which it was impossible for any honest man to remain neutral. It found the nobleman and his tutor on opposite sides; the former taking part with Charles and royal prerogative, the latter with the Parliament and popular rights. The loss of an honourable and lucrative post was not the only sacrifice which Owen had now to make at the call of duty; for about the same time he was disinherited, because of his opinions, of large estates, by a royalist uncle in Wales. Dispirited by these losses, he came to London, where sorrows of a deeper source, and having their origin in religious anxieties, greatly aggravated his sadness. Under the burden of these heavier griefs, he is described by his biographers as going on a certain Sabbath to hear the famous Presbyterian minister, Edmund Calamy, preach, when a rustic preacher, whose name he could never afterwards discover, to his great disappointment, entered the pulpit, and so met his difficulties in his discourse as to introduce him into a state of settled mental peace.

In 1642, Owen gave to the world his first literary production, *The Display of Arminianism*, which was intended to stem the current of theology that had become fashionable under the influence of Laud, and which, like all his other great compositions, holds its place, after the lapse of two centuries, as a standard work on the subject on which it treats. One incidental effect of its publication was to attract towards him the favourable notice of the committee for purging the church of scandalous ministers, who, in consequence, invited him to accept the pastorate of Fordham, a village overhanging the pleasant valley of the Stour between Suffolk and Essex. Not long after, he was transferred to the pastoral care of Coggeshall, an important market-town in Essex, where he soon found himself surrounded by a

congregation of 2000 people, numbers of whom were attracted by his weighty words from the neighbouring parishes; and while in this place he adopted views on the subject of church government which approximated to, though they never became identical with, the modern Congregational platform. From the same place emanated one of his greatest works, on which he owns himself to have expended much of the thought and toil of seven years, *The Death of Death in the Death of Christ.* During Owen's incumbency in this town, the neighbouring town of Colchester was besieged by the parliamentary army under General Fairfax; and Coggeshall having been the head-quarters of the general during the ten weeks of the siege, a friendship was formed between him and Owen which proved one of the links in the chain that drew him forth soon after into public life. His solid and enlarging reputation had already led to his preaching before Parliament; but at length he was unexpectedly summoned to preach on the day after the execution of Charles; and the manner in which he performed this task has been regarded by many as presenting one of the most vulnerable points in his public life. It is remarkable that throughout the entire sermon no reference is made to the awful tragedy of which he must have been aware that every mind was full; and this has been denounced as selfish and cowardly temporizing, and a forgetting of the fearless fidelity that became his position. But what evidence is there that he condemned the act of which it is well known that Milton and many others approved? And if he even hesitated in his judgment regarding it, then the silence which he adopted was his wisest and most honest expedient. The *Discourse on Toleration*, which he appended to this sermon when published, and which he dedicated to Parliament, occupied the same ground as the treatise of Locke on the same subject,—viz., that "errors in religion are not punishable by the civil magistrate, with the exception of such as in their own nature disturb the order of society"—did much to confirm the opinions of the religious party of which he was the head, as well as to shape the sentiments of the political leaders and patriots of the age. Cromwell had not yet chanced to meet with the pastor of Coggeshall; but on an early occasion, when he was once more appointed to preach before Parliament, the Lord-General and the chiefs of the army were present; and on the following day, happening to meet in the garden of Fairfax, proposals were made by Cromwell to Owen to accompany him on his contemplated expedition to Ireland, both as chaplain and in order to investigate and amend the affairs of the University of Dublin. It was with little grace that Owen yielded to the wishes of Cromwell, whose proposals were gradually assuming more of the shape and tone of commands; and with less grace still did his flock consent even to a temporary separation. But the issue deserved the sacrifice. For the effect of Owen's visit was to awaken a deeper interest in the religious condition of Ireland, to reform the rampant abuses of the university of Dublin, and to obtain for Trinity College valuable immunities, which it still enjoys. He had scarcely been welcomed back from Ireland to Coggeshall, when a command of Parliament ordered him, along with Joseph Caryl, to accompany Cromwell, in the cause of the Commonwealth, to Scotland, and cast him a second time amid the uncongenial din of sieges and of battlefields. It has been surmised that Cromwell desired his help in his anticipated discussions with the Scottish ministers; and some have even affirmed that his hand can be distinctly traced in the letters which Cromwell addressed to the ministers who had taken refuge in the castle of Edinburgh, which certainly abound in "lumbering sentences with noble meanings." Owen was allowed to return to Coggeshall many months before Cromwell received his "crowning mercy" at Worcester, but it was only to find himself soon after severed from its seclusion and quiet activities for ever; for on the 18th of March 1651, "the House, taking into consideration the worth and usefulness of John Owen, M.A., of Queen's College, ordered that he be settled in the deanery of Christ Church, in the room of Dr Reynolds;" and on the 9th of September of the following year, letters from Cromwell nominated him vice-chancellor of the university; and thus he entered the gates of Oxford to become the head of that great and ancient seat of learning, from which, ten years before, he had consented to be exiled for conscience sake.

The elevation of Owen to the vice-chancellorship gave him the virtual command of the university; and a mind of no common energy and wisdom was needed to restore it from the ruined state into which the civil wars had plunged it. Casting itself with something more even than common chivalry into the cause of the royalists, it had not only drained its treasury and melted its plate, but incurred an overwhelming debt; halls and colleges, empty of students, had been transformed into barracks and powder-magazines; while many of the students who had become soldiers, returning again to their books, brought back with them the insubordination and the profligacy which they had learned in the camp and the field. We do not wonder that the hand of Owen trembled as he seized the helm of Oxford at such a period. But his administration was firm, liberal, and conciliatory. While profligate students were treated with a rigour which led him in some instances even to interfere with his own hand, and cast them into "Bocardo," the studious were encouraged, and poor students of merit admitted to free commons. While the law furnished him with ample power for disturbing the worship of Episcopalians, it was allowed to proceed in peace over against his own door; the jealousy of the Presbyterians was disarmed by his placing some of their most eminent and qualified men in offices of high honour and emolument; the religious condition of the students was sought to be improved by the regular ministrations of himself and Dr Goodwin in St Mary's church; and so great was the change wrought in a few years in the general condition of Oxford as to evoke at length the reluctant praise of Clarendon.

But even the government of a university, and the raising of its affairs from the brink of ruin, were not sufficient to exhaust the resources of Owen's mind at this period. Several of his greatest theological treatises, such as his *Diatriba de Divina Justitia;* his work on the *Perseverance of the Saints*, which extends over more than five hundred folio pages; his *Vindiciæ Evangelicæ*, of almost equal colossal bulk; and his practical treatise on the *Mortification of Sin in Believers*,—which might have been sufficient of themselves to absorb and to recompense the energies of a lifetime,—bear date during the period of his vice-chancellorship. And during the same engrossing period he was consulted and employed by Cromwell on almost every measure which contained in it an ecclesiastical element, and had for its avowed object the promotion of religion in England. We find him, under the immediate auspices of the Protector, engaged with divines of other sects in devising measures of ecclesiastical union and comprehension; holding a prominent place in the famous "Committee of Triers," for ejecting ministers and schoolmasters of heretical doctrines or scandalous lives, and giving liberal advice, in the face of some fanatical and violent opponents, on the admission of Jews to settle and trade in England. On one part of his conduct alone at this period has he been severely blamed by his enemies, while even his friends have in general only ventured on a timid and hesitating defence. We refer to his allowing himself to be returned as representative for the university of Oxford to the Parliament which was summoned by Cromwell to meet in 1654, and to his taking his seat in the face of the representations that he was disqualified as a clergyman. His zeal for the endangered interests of his university was no doubt the motive which prompted him

to assert this doubtful position; but when he found the validity of his election so vehemently and plausibly questioned, he would have consulted his dignity more had he declined to sit. His patriotism shone out with true lustre not long after, when, on the proposal of a majority of Parliament to bestow upon Cromwell the crown and title of King, he joined with Fleetwood and the majority of the army in opposing the movement, and even drew up the petition which is known to have defeated the measure, and to have constrained Cromwell to decline the perilous honour. This bold step, which made the Commonwealth his debtor, so far estranged from him the affection of Cromwell, and cost him his vice-chancellorship. He resigned the presidency of Oxford, and yielded up the academic fasces into the hands of Dr Conant, his Presbyterian successor, with dignity. Referring to the number of persons that had been matriculated and graduated during his administration, to the professors' salaries that had been recovered, to his successful defence of the rights and privileges of the university, to the visible reformation of manners among its students, and to the fact that he left its treasury increased tenfold, "I seek again," said he, "my old labours, my usual watchings, my interrupted studies."

The next public movement of importance in which we discover the presence of Dr Owen, who had been diplomated some time before his administration at Oxford ceased, is in the conferences of the Savoy Assembly or Synod, in which a "Confession" expressive of the faith of the Independents was framed, after the manner of that which had already been drawn up by the divines at Westminster, and in which he took the leading part. Except in its sections on church order, it very closely resembled, not only in sentiment, but in phraseology, the earlier compend, and served at the time of its compilation both to unite the party of the Independents in closer confidence among themselves, and to distinguish them from violent and fanatical sectaries who sought to obtain sanction for their extravagances under a respected name. But before the Savoy conferences were ended, the great spirit of Cromwell had left the world; and his death had taken from the Puritans the best security for their precarious liberty. It is the work of general history to describe the resignation and retirement of Richard Cromwell, the mysterious secrecy and duplicity of Monk, and the return of Charles to the throne of his ancestors, without any pledge being obtained for the rights of conscience and for liberty of worship beyond the promise that "he would have respect to tender consciences"—a pledge which was intended to be kept only so long as it was unsafe to violate it. The act which restored the king restored the laws, both civil and ecclesiastical, to the state in which they had been at the commencement of the war; re-established the hierarchy; and constituted all classes of Nonconformists a proscribed class. The years which followed accordingly exhibit the gradual diminution of the liberties of the Puritans, and their subjection to a succession of acts which left them the alternatives of silence, or conformity, or suffering. Owen, by this time severed also from the deanery of Christ Church, became the pastor of a little flock in his native village of Stadham, hoping in that obscurity to escape notice without being forced to silence. Informers, however, armed with powers supplied by the Conventicle and Five Mile Acts, as well as by the Act of Uniformity, and prompted by bribes, drove him even from this narrow sphere, rendering it only safe for him to whisper truth in upper chambers, or in midnight assemblies. The breathing times from persecution which were afforded by the plague and by the great fire in London were eagerly improved by Owen and the other Puritan preachers, who reared vast wooden structures, called *tabernacles*, in which their long silent voices were once more heard by wondering and awe-struck thousands. The Act of Indulgence by Charles, however questionable in its motives or in its principles, only gave back to the Nonconformists what was their right; and, taking shelter under its precarious protection, Owen ventured to form a church in Leadenhall Street, where there gathered around him many of the heroes of the wars of the Commonwealth, "honourable women not a few," and pious noblemen, such as Lord Wharton, who, while they did not join his church, delighted to wait on his ministry. His confidential intercourse with these noblemen enabled him at times to learn the dangers that threatened Nonconformity, to apprise his suffering brethren in rural districts of coming evils, and it is even understood afforded him the gratification of helping to release Bunyan from his prison at Bedford. While the liberty of preaching was thus restrained and fitful, Owen did noble service at this period with his pen, and made some of his greatest bequests to posterity. Only once in his many controversial combats did he retire unquestionably vanquished from the field. Having rashly called in question the statements of Walton in his Polyglott, in reference to the various readings in the original manuscripts and versions of the Scriptures, and having with equal rashness ascribed consequences to those statements which they did not bear, he drew down the exposure of the proud ecclesiastic, who proved by the tone of his answer that he was not displeased to find an opportunity of laying the leader and champion of the Puritans in the dust. But he was more than compensated for his mortification in this instance by his triumph over Parker in his argument against toleration, and in his base attempts to blacken the character of many of the Nonconformists,—a work in which Owen was at length joined by Andrew Marvel, in his *Rehearsal Transprosed*, which turned the laugh even of Charles and his court against the truculent defamer, and held him up to immortal infamy. It would occupy undue space simply to enumerate all the works of Owen which belong to this closing period of his life, and which were often born amid the depression and the darkness of persecution. Amongst his devotional and practical writings, those on *Communion with God*, on *Temptation*, on *Indwelling Sin*, and on *Spiritual Mindedness*, belong to this period; among his controversial works, his discussions on *Schism*, and his *Animadversions on Fiat Lux;* among his theological treatises, his *Theologoumena*, his work on the *Holy Spirit*, and his *Christologia;* and among his expository compositions, that on the 130th Psalm, and his *Commentary on the Epistle to the Hebrews*,—the gigantic work of a gigantic mind, which, for exhaustive fulness, exegetical tact, matured learning, and profound piety which doubles his power as an interpreter, stands unapproached, except by the colossal work of the Dutch Vitringa on Isaiah. His latest writings make it evident that his desires were intensely turned, towards the close of his life, to two great objects—union among Protestants, and the resistance of Popery; while his course as an author was sublimely closed by his *Meditations on the Glory of Christ*, to the first sheets of which he gave his finishing touch on the day of his death. That death came while he yet stood only on the confines of old age. The calm and the kind hospitalities of Lord Wharton's house at Woburn, and the sweet seclusion of Ealing, could do little to alleviate the asthma and the torturing stone which were shaking his iron frame to pieces. On the 24th of August 1683, the anniversary of St Bartholomew's Day, the spirit of the great Puritan passed upward from amid the strife of tongues. Eleven days afterwards, a long and mournful procession, composed of more than sixty noblemen in carriages drawn by six horses each, and of many others, in mourning-coaches and on horseback, silently followed the mortal remains of Owen along the streets of London, and deposited them in Bunhill Fields, the Puritan necropolis.

The popular conceptions that have generally been formed

of Owen have considerably differed in more than one respect from the facts. He was not, as many appear to have imagined from the magnitude and abstruse nature of some of his works, a mere recluse who delighted to pore over dim manuscripts and dusty tomes, but a man of large popular sympathies, capable of social delights, and with such commanding appearance and propriety of manners as made him fit to stand before kings. And those are equally mistaken who conceive of him as a sermon-maker, rather than a preacher who is able to inspire and illuminate his words by the looks and the living voice. He is described even by adverse contemporaries, such as Anthony Wood, as "able to wind himself almost as he pleased into the affections of his auditory;" and we may rest assured that the helmed heroes of the Commonwealth would not have so often invited to address them, on their days of highest festival, a mummy or an automaton. More than any other of the contemporary leaders of the Puritans, Owen was a man of affairs, and possessed in remarkable combination that clear apprehension and firm grasp of great principles, that quick perception of character and discovery of hidden motives in other men, that knowledge of the times,—when to act, and when to economize strength,—which go to form the social leader, and even the great statesman. Baxter, with his impulsive energy, would have led his friends into difficulties, or, with his love of dialectics and fine distinctions, would have reasoned and speculated when he should have acted; Howe was more formed for meditation than for the rough details of common life; Owen was the pilot to whom the Puritans looked whenever they saw the gathering storm. As a theological thinker and author he holds his own distinctly-defined place among those Titanic intellects with which his age abounded. Surpassed by Baxter in point and pathos, by Howe in imagination and in the higher philosophy,—without the tenderness of Flavel, or the native elegance of Bates,—he is unrivalled in his power of unfolding the rich meanings of Scripture, of bringing out the exhaustless treasures from the mine of a text, of disclosing the harmonies and connections of passages of Scripture; of doing the work of a biblical interpreter, one among a thousand. There is scarcely a great subject in the wide range of inspired theology on which he has not written a treatise that has now lived for two centuries; and his works are to this hour the armoury to which modern controversialists go the most readily to equip themselves in the well-tried panoply of the strong and sturdy Puritan. He was accustomed to read everything beforehand on the subject on which he intended to write, especially the writings of opponents; and when he sat down himself to write, he exhausted his theme, leaving to an author that should attempt to follow him not even the gleanings at the corners of the field.

His style has most hindered his popularity. Many fine passages might no doubt be extracted from his writings; but in general his manner of expressing himself is lumbering, involved, and unmusical, and the golden thoughts but seldom owe anything to skilful setting. We have elsewhere compared his motions to those of the elephant—slow and ungainly, but with a tread that shakes the earth, and with a resistless force that breaks its way through tangled thickets and serried ranks of armed men.' In his writings he was pre-eminently the great theologian, and in his practical counsels the Nestor, of the Puritans. (A. T.)

OWEN, *John* (called in Latin, *Ovenus* or *Audoënus*), a writer of Latin epigrams, once very popular all over Europe, was of Welsh extraction, and was born at Armon in Caernarvonshire. He was educated under Dr Bilson at Wykeham's School, Winchester, and afterwards studied at New College, Oxford, where he received a fellowship in 1584, and took the degree of Bachelor of Laws in 1590. (Wood, *Ath. Ox.*, vol. i., col. 471.) Throwing up his fellowship during the following year, he turned schoolmaster, and taught successively at Trylegh, near Monmouth, and at Warwick. He soon became distinguished for his perfect mastery of the Latin language, and for the humour, felicity, and point of his epigrams. As a writer of Latin verse he takes rank with Buchanan and Cowley. Those who, with Dryden, place the epigram "at the bottom of all poetry," will not estimate Owen's poetical genius very high; yet the continental scholars and wits of the day used to call him "the British Martial." "In one respect he was a true poet," says a biographer; "namely, he was always poor." He was a staunch Protestant besides, and could not resist the temptation of turning his wit against Popery occasionally. This practice caused his book to be placed on the *Index Expurgatorius* of the Romish Church in 1654, and what was yet more serious, led a rich old uncle of the Catholic persuasion, from whom he had "great expectations," to cut the epigrammatist out of his will. When the poet died in 1622, his countryman and relative, Bishop Williams of Lincoln, had him buried at St Paul's Cathedral, London, where he erected a monument to his memory bearing an elegant epitaph in Latin. (See Dugdale's *Hist. of St Paul's.*) Owen's *Epigrammata* are divided into twelve books, of which the first four were published in 1606, and the rest at four different times. The best editions are those printed by Elzevir and by Didot. Translations into English, either in whole or in part, have been made by Vicars, 1619; by Pecke, in his *Parnassi Puerperium*, 1659; and by Harvey in 1677, which is the most complete. La Torre, the Spanish epigrammatist, owed much to Owen, and translated his works into Spanish in 1674. French translations of the best of Owen's epigrams have been published by A. L. Lebrun, 1709, and by Kérivalant, 1819.

OWEN, *William*, one of the ablest of English portrait-painters, was the son of a bookseller, and was born at Ludlow in Shropshire in 1769. After receiving a good education in his native town, he repaired to London at the age of seventeen, and began to study under Catton, the academician. He sent his first portrait to the Somerset House exhibition in 1792, at the time when Lawrence, Beechy, and Hoppner were in their palmiest days. The easy and elegant touch, and the clear and strong perception of character which the young artist displayed, soon exacted attention. William Pitt sat to him in 1798; and from that time the merits of Owen in portraiture began to be generally recognised. The portraits of the Duchess of Buccleuch, Sir William Scott, Cyril Jackson, the Bishop of Durham, and the Marquis of Stafford, came to be admired for their freedom, vigour, and excellent light and shade. Owen was elected a member of the Royal Academy in 1806. The Prince of Wales made him his portrait-painter in 1810, and would have knighted him in 1813 had not the artist declined the honour. Meanwhile Owen had been rising to an equally high place in another province of his profession. His fancy sketches, especially that of "Peasants Resting by the Roadside," and that of "The Fortune-teller and the Lady," were remarkable for their exquisite delineation of ordinary life, and attracted crowds of admirers. Towards the close of his life, however, Owen found no time to indulge in these sportive exercises of the pencil, and was obliged to confine himself to portraiture. In 1818 his prosperity was at its height. The portraits he had painted amounted to nearly two hundred, and his income had risen to about L.3000 a year, when an attack of disease shook the brush from his hand. He continued to linger on in great debility, till a dose of opium, which he had swallowed by mistake, put an end to his existence on the 11th February 1825. (Cunningham's *Lives of Painters*, &c.)

OXENSTIERNA, COUNT AXEL, a distinguished Swedish statesman, was born at Fano in Upland in 1583. After studying at the universities of Rostock, Jena, and Witten-

berg, and graduating in arts, he visited most of the German courts, and returned to Sweden in 1602. Accomplished in scholarship, versed in foreign politics, taking to business spontaneously and eagerly, far-sighted, faithful, and patriotic, Oxenstierna now entered upon the career of a statesman under Charles IX. He conducted an important diplomatic mission in 1606, became a senator in 1608, and presided over the regency which governed the country during the superannuation of the king. His influence rose still higher on the accession of Gustavus Adolphus in 1611. The chancellorship, the chief office of the state, was conferred upon him; he became the able second of his sovereign in advancing the interests of his native country, and in defending the liberties of Europe; and it was soon proved that he was not unworthy to consummate by the art of diplomacy the enterprise which the royal hero had begun by the art of war. His negotiations brought to an advantageous close in 1613 one war with Denmark, and in 1617 another with Russia. It was, however, in 1632, when Gustavus fell at Lutzen, that Oxenstierna rose to the height of power. The great task of maintaining, in the room of the fallen hero, the cause of Protestantism, was entrusted to him; and that task he performed amid the onset of enemies and the dissensions of allies, with unwearied vigour and ultimate success. His authority as chancellor, and as one of the guardians of Queen Christina, was exerted in introducing an improved plan of finance, removing burdens from trade, and patronizing learning. He also succeeded in checking the misrule incident to a minority; and in 1645 placed an unimpaired government in the hands of the young princess. The high public influence of Oxenstierna declined considerably towards the close of his life, in consequence of the determined opposition which he offered to the abdication of Queen Christina. Although sometimes consulted by Charles Gustavus, he lived thenceforth in private till his death, in 1654.

OXFORD, the seat of the university and the capital of the county of the same name, is situated 53 miles from London by the road, and 63 by the railway. The name, as shown by Domesday the old Saxon chronicle, and the city arms, is derived from its originally being a ford for oxen. It stands in a richly-watered valley between the confluence of the Cherwell and the Isis; and when seen from the rising ground near the city, its appearance is singularly beautiful and impressive, from its panorama of towers and domes, stately collegiate and public edifices, amid gardens and waters.

In English history Oxford occupies an important position, second perhaps only to London. Its origin as a place of note is generally assigned to Alfred; but both an earlier and a later date than this have found favour. Before the time of the Conqueror we hear of it as an abode of the Saxon kings, of its having been thrice destroyed by fire, and of its having suffered severely from the ravages of the Danes. It is one of the seven fortified towns, during the Danish invasion, mentioned in the Saxon chronicle. At the time of Edward the Confessor there were 721 inhabited houses in Oxford; and at the time of the compilation of Domesday only 243. The town had resisted William, and this decrease was the result of his vengeance. The neighbourhood was strongly anti-Norman; and Robert D'Oiley, the chieftain to whom this tract of country was assigned, built a castle on the western side, to overawe the surrounding country. Henry I. was frequently here and at his neighbouring park of Woodstock. In the time of King Stephen, who held here his first gathering after his return from Normandy, we read of it as a place of great strength; and the town figures largely in the civil wars of that time. In 1141, after a long siege, it was taken by Stephen; Maud made her escape, dressed in white, over the frozen river, which was covered with snow. Henry II. visited Oxford, and he gave the city its great charter, assigning to it all the privileges and liberties of London, besides some extraordinary privileges. Richard I., who was born here, and for whose ransom the city raised a large contribution, confirmed these privileges, and greatly added to them. Simon de Montfort's celebrated Mad Parliament of Henry's rebellious barons was held here, and ordained the famous "Provisions of Oxford." The original writ of the king to the people, directing them to abide by the decisions of the new council of the nation, has been discovered in the city archives.

The most striking feature in the history of Oxford is the bitter hostility that ever prevailed between the town and the university. Their respective jurisdictions, rights, and privileges constantly came into collision; and these feuds, in that rough age, were frequently attended by most disastrous and fatal results. (See UNIVERSITIES, *Oxford*.) By far the worst of these was John Bereford's riot in 1355. The colleges and halls were completely sacked by the mob; many lives were lost, and vast injury was done. The town was placed under an interdict; and the university resigned its charter, as if insecure of its existence,—an example which was followed by the town. Both the charters were subsequently restored, with alterations in favour of the university. The latter part of the fourteenth century is a bright period in the annals of Oxford. It was the first seat of Protestantism, and Wycliffe, the morning-star of the Reformation. Henry VIII erected Oxford into a separate see: it had before been included in the diocese of Lincoln. In 1555, under Queen Mary, Ridley and Latimer suffered here at the stake, and subsequently Archbishop Cranmer. Queen Elizabeth visited Oxford, and displayed her erudition by making a long Latin speech to her learned audience. The plague raged here with dreadful severity in her reign. As fatal as the plague was the remarkable jail-fever which happened here in 1577, respecting which Lord Bacon has written. During a trial, several hundred persons sickened in court, among whom were jurors and magistrates, the high sheriff and the chief baron. James I. visited Oxford frequently; and the first Parliament of Charles I. was held here, in consequence of the plague being prevalent in London.

Oxford was greatly distinguished in the parliamentary wars for its loyalty and constancy to the royal cause. When the king wrote for help from York, the university sent him all their plate and ready money. In 1642 the city was occupied by the parliamentary troops; but after the battle of Edgehill the king established his court and camp here. The city was a second time occupied by the Parliamentarians, and again by the king. Oxford was one of the last cities that remained loyal to Charles, nor was it finally surrendered till every hope of saving him was lost.

Oliver Cromwell became the chancellor of the university. A parliamentary commission expelled some leading loyalists, and set aside some ceremonies that were opposed to the prevalent Puritanic spirit. In 1665, the year of the great plague, Parliament assembled in Oxford. The Parliament of 1681 was also summoned here, but was dissolved after a few days. James II.'s invasion of the rights of Magdalen College is closely connected with the Revolution, and belongs to English history. Oxford gave the title of Earl to the ancient family of the Veres, which became extinct in the twentieth earl in 1702; and in 1711 the title was revived in favour of Speaker Harley.

Oxford is in the form of an ellipse, and, including its suburbs, is at least 3 miles in circumference. It has its high steward, recorder, mayor, sheriff, aldermen, councillors, magistrates; and returns two members to Parliament. There is a free reading-room and library, and public baths and workhouses. The city is rich in various charities and institutions, among which should be especially mentioned the Ratcliffe Infirmary, and the Ratcliffe or Warneford Lunatic Asylum. Its civic buildings comprehend the town-hall, erected in 1753, and the council-chamber, where royal and illustrious visitors are received, adorned with an interesting collection of portraits. In 1840 a new county-hall and courts were erected, at a cost of about L.15,000. The castle of Oxford appears, from some interesting remains,—the crypt, the well-room, and the tower,—to have been an ancient Saxon fortress before its occupation by the Normans. The great ditch is now a mill-stream, and the castle is the county jail; but great taste and skill have been exerted to preserve the ancient remains as far as possible.

Anciently the city was strongly walled, and there are many mural remains, especially at New College. The principal streets are wide and regular; the four principal thoroughfares cross each other in a central situation by Carfax Church. The famous High Street commences with the beautiful bridge over the Cherwell. On its left are the Botanic Gardens, sloping down to the river, and adorned with fountains and conservatories. It passes the Magdalen Tower, one of the finest architectural ornaments of the university, and extends westwards, lined with numerous collegiate buildings. The intermingled town edifices add to the picturesque, while the curvature of the street gradually opens up fresh and striking points of view. Broad Street runs parallel with the High Street, deriving its name from its vast area. It was here, opposite Balliol College, that Ridley and Latimer suffered. Near the junction of Broad Street with St Giles, a beautiful Gothic monument has been erected to their memory—the Martyrs' Memorial. St Giles is a spacious street, somewhat irregularly built, with a church at each end, and a row of trees on each side. Beaumont Street, a fine modern street,

branches from St Giles, and fronts Worcester College. In Cornmarket Street are the buildings of the Union Society, who have recently erected a large debating-room, ornamented with wall-paintings by eminent pre-Raphaelite artists, illustrative of the Arthurean cycle of romance. At the end of Port Meadow—a pasture-ground belonging to the citizens, of 439 acres—are the ruins of Godstowe Nunnery, famous as the burial-place of Fair Rosamond. Iffley, with its beautiful Norman church, Headington Hill, Shotover Hill, Bagley Wood, and Nuneham Park, are well known localities in the neighbourhood of Oxford.

We now proceed to give some account of the more important public buildings of Oxford, chief among which are the colleges. (The history, constitution, and statistics of the university and colleges, will be found in the article UNIVERSITIES) We commence with Christ Church, from its importance and colossal proportions. Its Norman foundation and earlier buildings date from 1154. Its origin as a college is due to Wolsey, and it was originally called Cardinal College. But on his attainder in 1529, all the buildings and revenues lapsed to the Crown. In 1546 Henry transferred the new see of Oxford from Osney Abbey to Christ Church, and constituted it in the mixed form of a cathedral and academic college. The western frontage of Christ Church is of great extent and magnificence. It terminated at each end by a projecting turret, and between the two is the stately gateway, above which rises the tower containing the great Tom of Oxford, a bell weighing 17,000 lb., originally brought from Osney Abbey. The great quadrangle occupies a large area, and has a broad terrace on every side. The entrance to the hall is by Wolsey's ample staircase, above which Bishop Fell erected a roof of exquisite tracery, supported by the long slender stem of a single clustered column. The hall is very imposing, having a lofty oaken roof carved and gilded, armorial bearings emblazoned round the cornice, and numerous portraits on the walls. The college chapel, which is the cathedral of the diocese, is of great antiquity, and has traces of various additions and alterations in the course of time. It is rich in ancient windows and monuments, among which is the shrine of St Fridiswide; the choir, of black and white marble, has a Gothic roof of remarkable beauty. In 1857 the Dean and Chapter removed the wainscotting, restored the columns, and threw the choir and nave into one. The effect is exceedingly good, and there is a large gain of space. The chapter-house adjoining is an exceedingly remarkable and interesting room. The library contains a large collection of books, some rare coins and sculptures, and a splendid collection of chiefly Italian pictures, the bequest of General Guise. Merton College is interesting as the earliest instance of the present collegiate system, the founder being the first who settled the students in a regular abode and under a fixed discipline. Its chapel, a cathedral-like structure, is also one of the parish churches. The ante-chapel and the tower are very noticeable, as also are the library and hall. Exeter College has a long and handsome east frontage, the effect of which is greatly marred by the narrowness of the street which it partly lines. Of late years the college has almost been entirely taken down and rebuilt; some splendid piles of building are in progress, including a noble chapel. A new and handsome chapel has very recently been built for Balliol College, a college which has gained an enviable pre-eminence through the scholastic distinctions obtained by its members. New College is one of the most splendid structures of the university, and the chapel is by far its most striking feature. In the east end, tier rises above tier of canopied niches; and the altarpiece is almost unexampled for decorative richness, including six sacred subjects sculptured in marble by Westmacott. The ante-chapel is loftily roofed, sustained by two tall splendid pillars; its great west window is executed from a design by Sir Joshua Reynolds. The costly crosier of the founder, which is exhibited, is an object of great interest. Adjoining the chapel the cloisters inclose a square, at one corner of which rises an embattled tower.

The venerable buildings of Magdalen College present a low embattled front on the south side to the High Street, and here rises the noble tower mentioned above. Entering through a fine modern gateway, designed by Flaxman, and passing through the court which fronts the President's spacious lodgings, we pass into the chief quadrangle, through a second gateway, surmounted by a very beautiful and remarkable tower. A venerable cloister, around the interior of which is placed a series of curiously-sculptured hieroglyphics, surrounds the whole of the spacious quadrangle. The beautiful chapel was greatly defaced at the times of the Reformation and Rebellion, but it still ranks as one of the finest in the university. Each side of the choir has a range of five windows in *claro obscuro*; underneath the altarpiece is Morales' celebrated picture of Christ bearing the Cross; the pavement is of black and white marble; a screen of great beauty separates from the ante-chapel. This last has many monuments, and is lighted by eight fine windows in *claro obscuro*; the west window has Swartz's representation of the Last Judgment. The hall is an extensive and handsomely decorated room. The pleasure-grounds of the college are highly celebrated, consisting of a grove planted with noble elms, and the Magdalen meadow surrounded by shaded walks.

All Souls' College has a long frontage in the High Street, from which it is entered by two gateways It has two quadrangles, the first erected by the founder, plain and ancient; the second is in the later English style, and is very striking, though not without blemishes in an artistic point of view. The chapel and hall are worthy of great attention; but the library is perhaps the most striking feature of the college. It was founded by a bequest of books and money by Colonel Codrington. There is a large collection of works and many rare manuscripts; the spacious room is decorated with busts and vases, and the cases are separated by Doric and Ionic pilasters of dark green. The library of Queen's College is a noble room, taking up the entire western side of the inner court of the college, and has one of the largest collections of books in the university.

Among the buildings connected with the university, stands the Bodleian Library, founded through the munificence of Sir Thomas Bodley, and opened to the public in 1602. We do not here enter into any account of the countless treasures belonging to this invaluable library. The picture gallery of the Bodleian has a noble collection of British historical portraits, besides other paintings, busts, models, and various valuable curiosities. The library and gallery occupy a large portion of the quadrangle called the Schools; in an apartment on the north side are kept the Arundelian Marbles. The divinity school is a magnificent specimen of later English architecture; the tall windows, with their slender munnions and the exquisite tracery of their arches, are very striking; the roof, moreover, is of great beauty. Northwards of the schools is the Clarendon printing-house, erected from the profits of the *History of the Rebellion*, the copyright of which was presented to the university by the author's son. It was erected by Sir John Vanbrugh, the north front has a bold portico with massive Doric pillars; there are pediments to the four sides of the building, and statues of the nine Muses on the summit: Lord Clarendon's statue is over the south entrance. The Clarendon is now used for other university purposes, the university having been able from its profits to build a new printing-house. This is the most complete and largest printing-house in the world, with the exception of the celebrated one at Paris. The buildings occupy two acres and a half, and form a square, with a splendid gateway modelled after the arch of Constantine at Rome.

The Radcliffe Library was finished by Gibbs in 1749, from L.40,000 bequeathed by Dr Radcliffe. Situated in the centre of a square in the middle of the city, its vast dome is seen on every side to great advantage, and gives Oxford an appearance which somewhat reminds the traveller of the distant view of Rome. The building is circular, the ground-floor is unoccupied, and the principal room, which is probably the most beautiful in the university, is gained by a staircase. It is enriched with casts, busts, and statuary, and a valuable collection of works relating to medicine and natural history. The pavement is of Portland and Bremen stone; above the basement are duplicated Corinthian columns, supporting an enriched entablature, above which is a balustrade ornamented with urns; between the windows are sculptured foliage, fruit, and flowers. Kneller's portrait of the founder is over the principal entrance.

The Sheldonian theatre was constructed in 1664 by Sir Christopher Wren, at the expense of L.12,470 to Archbishop Sheldon, who left an additional L.2000 for its maintenance. It is built after the theatre of Marcellus at Rome, and can contain nearly 4000 persons. A new roof was constructed in 1802 with a magnificently-painted ceiling. It is used for university meetings and occasional concerts; in the summer term the commemoration of founders and benefactors is held, when honorary degrees are conferred upon distinguished characters.

The Ashmolean museum, provided for the reception of the celebrated collection made by the Tradescants, presented to the university about 1682 by Elias Ashmole, was erected after a design by Sir Christopher Wren. There is a valuable collection of coins, medals, manuscripts, and paintings; an important antiquarian library left by Dugdale and others; and extensive collections devoted to chemistry, mineralogy, and experimental philosophy. To provide for their increasing stores, part of which have been taken in by the Clarendon, and also to extend the study of the natural sciences, the university a few years back, resolved to build a new museum. This is now rising in proportions of vast extent and magnificence in the parks, and bids fair to be one of the finest ornaments of Oxford.

The Taylor Institute for modern languages is another magnificent structure, which has been added to Oxford of late years. It contains a fine reading-room and library, chiefly of works in mo-

dern languages, and a magnificent collection of paintings, drawings, and statuary. We should also mention the observatory and music-room. There are numerous churches in Oxford, and the chief of these may be considered that of St Mary, the university church. The chancel was built in 1492, the rest of the church in 1498. Both the exterior and interior of this beautiful church are striking, the splendid tower and spire being special objects of remark. In the north part of the church is the monumental chapel of Adam de Broom. The church of St Peter in the east is one of the most ancient in England, dating back probably to the ninth century. The chancel is spacious, with a cluster of columns and a finely ornamented roof. Beneath the chancel is the crypt, still in good preservation, its arches supported by low ranges of Saxon pillars. In striking contrast to this is All Saints' church, built in the Grecian style after a design by Dean Aldwick, with a profusely-ornamented interior.

There are a number of other old churches, and of late years, to meet the wants of an increasing population, new churches have been built of great neatness and utility. There are a number of interesting remains of ancient religious houses in Oxford and its neighbourhood. Dissenters of various sects have their different chapels, which are neat and spacious. The city has a general air of cheerfulness, cleanliness, and prosperity. The university authority is paramount, extending five miles in every direction. Pop. (1851) 27,843. (F. A.)

OXFORD, Earl of. See Harley.

OXFORDSHIRE, an inland county of England, is bounded on the S. by the Thames, and, as it follows the windings of that river, is in shape very irregular. The breadth near Oxford is only 7 miles, its greatest breadth in the north is 38 miles, and the extreme length nearly 50 miles. The River Cherwell bounds it on the N., with the counties of Warwick and Northampton; Buckinghamshire is on the E.; and Gloucestershire on the W. It contains 479,267 acres.

The surface of the county is very varied, from the rich water meadows of the Thames, to the high, bare chalk hills. For a southern county, the climate is certainly cold; dense fogs often hang heavily over the Chiltern Hills and woodlands, and, according to meteorological returns, there is considerably more rain in Oxford than in London. The geological strata of the county confer upon it a directly agricultural character, being those termed the secondary series, including also a small portion of the lower bed of the tertiary. These scarcely yield any minerals: the varying constituents of the strata exhibit alternately clay and stratified rock and sand. Here there is a numberless variety of soils which are not capable of a very strict classification, and as regards the practical agriculture, we must chiefly consider superficial accumulations and alluvial deposits. The soil by the Thames is rich black mould; in the midland districts it is the decomposed stone-brash or limestone, with sand and loam; in the north there are the fertile red soils; and in the Chilterns a sandy loam laid on chalk. These are the main agricultural divisions.

Owing to this character of the county, there is no particular system of agriculture, and the same course is scarcely pursued in the same parish or on the same farm. An irregularity of cropping is unavoidable. Wheat, barley, and oats are generally cultivated; pease and beans occasionally. The turnip, both the common and the Swede, are grown to a great extent; it is also a practice to sow beans and pease mixed, chiefly on the lighter lands, and this is called *poulse*. Clover, trefoil, and sainfoin are grown to a great extent. On the banks of the Thames and the Cherwell the best feeding lands are found; and in some places the meadows are mown twice a year. The Thames meadows are subject to frequent and injurious inundations. There have been as many as seventeen floods in a year; 6000 acres have been under water, and three-fourths of the hay has been known to be swept away. A good system of artificial drainage is much wanted; neither are there many water-meadows, though the soil is well adapted for irrigation. It is by no means a grazing county, the stock being chiefly kept for dairy purposes. The county is celebrated for its half-breds or Down-Cotswolds, which in process of time has become a distinct breed of sheep, the management of which is brought to a high state of perfection. The use of the thrashing-machine has become very common.

Great improvements have taken place in the last twenty years by the extension of inclosures. The hedging is good, the ditching very inferior; in the N.E. of the county stone walls are common. In 1853 an act was passed to disafforest the wild Wychwood Forest, and to constitute it a parish, with church, schools, &c. The woods and wastes of Wychwood lie between the Evenlode and the Windrush; quarries of stone, slate, and one of marble are found beneath its stone-brash soil; springs of water and clear rills add great beauty to the wild scenery; the glens and copses are crowded with deer and game. In Cornbury Park are some ancient oaks and long avenues of stately beeches; and the antiquities connected with the forest are numerous and interesting. The farm-steadings in the county are of a very inferior description, and the farms are for the most part small. On the Blenheim estate the farming is of a first-class character. Leases are seldom given; the tenant generally holds from year to year, a system which is a fatal bar to improvement on the part of the tenantry. Under the colleges, however, families have held land from generation to generation. One-sixth of the income from land belongs to the university and other religious bodies; and the general impression seems to be that they are far from being well managed.

Oxfordshire is remarkable for its many rivers, the principal being the Evenlode, the Windrush, the Cherwell, and the Isis; the last, when it is joined by the streamlet Thame, below Dorchester, is called the Thames. The river by Oxford should rightly obtain the name; and indeed it is so styled in the earlier charters. The banks of the river are studded by various beautiful country seats; the prospect is always pleasing and sometimes beautiful, growing, however, somewhat bare and tame towards the N. and N.W. Among the different seats, the famous residence of the dukes of Marlborough stands pre-eminent; we should also mention Nuneham-Courtenay, Wroxton Priory, and Stanton-Harcourt. The antiquities of the county are numerous and interesting: there are several Roman and some very curious British remains; the Ikenald Street, one of the four prætorian ways, skirted the base of the Chiltern Hills. There are some ancient tumuli and encampments in the neighbourhood of Wychwood Forest; and a considerable number of Roman coins, and even some old British coins, have been discovered. In this county, too, are many marks and remains of the old warfare between the Danes and Saxons, chiefly in the way of military entrenchments and sepulchral mounds. Interesting reminiscences of the civil wars are everywhere suggested. To the geologist Oxfordshire is a very interesting county; its beds afford some of our national geological characteristics, and abound with interesting and rare fossils.

We cannot speak highly of the accommodation provided for the peasantry; and the character of the Oxfordshire labourer for temperance and intelligence does not stand high. Some of the roads in the vicinity of Oxford are in a disgraceful condition. Of late years much has been attempted in extending education and church accommodation among the poor, and with favourable effect. The smaller towns of Oxfordshire are mentioned elsewhere: the more noteworthy are Banbury, Woodstock, Henley-on-Thames, Witney, Bampton, Bicester, Burford, Chipping-Norton, Thame, Watlington. These are the market-towns; the two first are also boroughs, each returning a member to Parliament; and the county returns three members, elected at Oxford.

The population of the county amounted in 1851 to 170,439; in 1841 it was 163,143; while in 1801 it was

111,977. Thus, while England has more than doubled its population in the half century, this county, in common with other midland counties, has only increased 52 per cent. It contains 1 city, 11 market-towns, 14 hundreds, and 278 parishes. It contains a population of 2·8 acres to a person; throughout England the proportion is 1·9 acres. Oxfordshire contained in 1851, in all, 504 places of worship, with 110,666 sittings. Of the former, 266 belonged to the Church of England, 116 to Wesleyan Methodists, 50 to Baptists, 43 to Independents, 12 to Quakers, and 8 to Roman Catholics. There were in the same year, 591 day-schools, with 23,498 scholars (12,135 male and 11,363 female). Of these schools 247, having 16,574 scholars, were public; 9, with 613 scholars, being supported by general or local taxation; 51, with 3014 scholars, by endowments; and 181, with 12,582 scholars, by religious bodies. Besides these, there were 314 Sunday-schools, with 19,776 scholars (9573 male and 10,203 female), and 19 evening schools, with 373 scholars. (F. A.)

OXIDE, and OXIDATION. See CHEMISTRY.

OXUS (Ὦξος), a great river of Central Asia, called by the natives on its banks the *Amoo*, and by Turkish and Persian writers the *Jihon*, rises in a lake called Sari-Kol, about 15,600 ft. above the sea, among the Pamir Mountains or Tartaric Caucasus, in Badakhshan; Lat. 37. 48. N., Long. 73. 40. E. The river issues from the west end of the lake, and thence flows N.W. until it falls into the Sea of Aral. Near its origin the Oxus receives several tributaries from the Hindoo Koosh; and during its course there are many large affluents of which comparatively little is known. Its whole length is about 1300 miles, and it drains an area estimated at about 221,256 square miles. The most remarkable fact connected with this river is, that the testimony of antiquity is almost unanimous in representing the Oxus as flowing into the Caspian. Pomponius Mela is the only ancient writer whose description of the Oxus agrees with its modern course; but his single testimony cannot be considered of much value, since both Strabo, who lived but a short time before him, and Ptolemy, within a century after, assert that in their time it followed a different course; while the former writer informs us that merchandise was conveyed from the East by this river to the Caspian, and thence to the Euxine. It is therefore the opinion of most modern authorities, that the river did formerly discharge itself into the Caspian; and some traces of its mouths, it is thought, have been discovered in the Bay of Balkan. Humboldt supposes, that down to the time of Alexander the Sea of Aral and the Caspian formed one great sea; that by some violent convulsion, or by the gradual effects of evaporation, they were separated; and that the Oxus then had two branches, one flowing to the Caspian, and the other to the Aral, the former of which has become dried up, so that the latter only now remains.

OXYGEN. See CHEMISTRY.

OYER AND TERMINER (Fr. *to hear and determine*), two words in ancient law French, applied to the commission by which authority is granted to certain individuals to establish a court of criminal judicature for *hearing and determining* certain specified offences.

OZANAM, JACQUES, a laborious French mathematician, was of Jewish extraction, and was born at Bouligneux, in the principality of Dombes, in 1640. His passion for mathematics was developed at an early age. On the death of his father, who had designed him for the church, Ozanam abandoned divinity and took to mathematics, at Lyons. His removal to Paris soon afterwards was the means of increasing alike his zeal and his fame. He devoted much of his time to his pupils, both native and foreign; and he wrote many valuable mathematical works. The latter part of the career of Ozanam was clouded with domestic suffering; and the war of the Spanish succession deprived him of many of his pupils. Yet he preserved his cheerful and amiable disposition, until a stroke of apoplexy closed his career on the 3d April 1717.

Among a great number of works on theoretical and practical mathematics, the best known and most esteemed are the *Dictionnaire Mathématique*, Paris, 1690, 4to; *Cours de Mathématiques*, ibid., 1693, 5 vols. 8vo; *Récréations Mathématiques et Physiques*, ibid., 1694, 2 vols. 8vo, improved by Montucla, Paris, 1778, 4 vols. 8vo, and still further improved in the English edition of Dr Hutton, London, 1803, 8vo. Ozanam left in manuscript a treatise on the Analysis of Diophantus, which was in the library of D'Aguesseau. (See his *Eloge* by Fontenelle, the *Mémoires* of Niceron, and the Dictionary of Chauffepié.)

OZELL, JOHN, an industrious translator, was born about the close of the seventeenth century. At the school of Ashby-de-la-Zouch, and at Christ's Hospital, he acquired a knowledge of Latin, Greek, and Hebrew. Having entered an accountant's office, his leisure hours were devoted to the cultivation of the literature of France, Spain, and Italy. He published metrical versions of some of the works of Molière, Corneille, Racine, Boileau, and Tassoni; and prose translations of Fenelon *On Learning*, *The Port-Royal Logic*, Rabelais' works, *Don Quixote*, Vertot's *Revolutions of the Roman Republic*, and a Life of Veronica. The vanity of the translator has preserved his name longer than the merit of his translations. The conceited author was exalted to a place among the immortal dunces of Pope; he retaliated by inviting the public, in an advertisement in the *Weekly Medley* of 1729, to judge between his genius and that of the great poet; Pope replied by inserting the absurd advertisement into the notes of a succeeding edition of the *Dunciad*; and the translator thus acquired a notoriety, which still lives. He died in 1743.

OZEROV, VLADISLAV ALEXANDROVITCH, a celebrated Russian tragic poet, was born in the government of Tver in 1770. The early part of his life was spent in the public service. At the age of six he entered the army as a cadet, and on retiring from military life he had attained to the rank of major-general, and received a civil appointment. Meanwhile he devoted his leisure to the composition of tragedy; and surpassed all preceding Russian dramatists in his knowledge of stage effect, in the conception of his plots, in the pathos of his incidents, and in the warmth and harmony of his poetical colouring. The *Death of Oleg* in 1798, *Œdipus* not long afterwards, *Fingal* in 1805, and *Demetrii Donskoi* in 1807, were all received with deserved applause by the public. The only other tragedy that the author produced, although he retired from the public service in 1808, was *Polyxena* in 1809. During the rest of his life a settled melancholy seems to have overclouded his mind and chilled his imaginative faculty. He died in 1816. The complete works of Ozerov, containing, besides his tragedies, some lyric poems, and accompanied by a Life, were published by Prince Viazemsky, in 2 vols., St Petersburg, 1818.

OZIERI, a town of the island of Sardinia, division of Sassari, in a valley surrounded by hills on all sides but the N., 15 miles E.S.E. of Sassari. It is substantially built on uneven ground; but the streets are narrow and irregular. Ozieri is the seat of the Bishop of Bisarcio, the town of that name having long since entirely fallen. It contains a cathedral, several other churches, a court-house, town-hall, prison, episcopal college, and several other schools. Woollen and linen stuffs are manufactured; and some trade is carried on in these, as well as in horses, cattle, hides, wool, &c. Pop. 8433.

OZORKOV, a town of the Russian empire, in Poland, province of Warsaw, stands on the right bank of the Bsura, 75 miles W.S.W. of Warsaw. Considerable manufactures of cloth are carried on. Pop. 8000.

P.

P, the sixteenth letter of the English alphabet, is a consonant of the labial series, and is formed by a close compression of the anterior part of the lips. As may be ascertained from inscriptions and coins, the Latin form of this letter, which we have adopted, originated in shortening and bending round the right leg of the Greek Π, the character representative of the hard labial in that language. (See ALPHABET, with Plates XIX. XX. and XXI. corresponding.) P is liable to be converted with all labials, and is not unfrequently interchangeable with other letters. The soft labial B is most frequently convertible with this letter, however, of which we have examples in nearly all languages, and especially in the German. In addition to the labials *m, v, f, pf,* P is likewise occasionally interchangeable with *c, k,* or *q,* with *t,* and with *pt.* When P is aspirated or followed by an *h,* it is equivalent to the Greek φ, and corresponds in sound with the English *f,* as in *physic, philosophy,* &c. In some words borrowed from the Greek, the letter P is mute, as in *psalm, ptisan,* &c. If we may judge from the line of Ugutio, P stood for 100 among the ancients; for he says "P similem cum C numerum monstratur habere." Baronius, however, is inclined to think that it represented T. With a dash over it ($\bar{P}$), it stood for 400,000. Among the Greeks π′ was used for 80, and π for 80,000; but on inscriptions Π stood for 5 (πέντε). Among physicians P stands for *pugil,* or the eighth part of a handful; P.Æ., *partes æquales,* or equal parts of the ingredients; P.P., *pulvis panium,* or Jesuits' bark in powder; and *ppt., preparatus,* or prepared. In music *p.* stands for *piano,* or softly; *pp.,* for *pia piano,* or more softly; and *ppp.* for *pianissimo,* or very softly. In printing, *p.* stands for *page,* and *pp.* for *pages.* (For other abbreviations of P, see the article ABBREVIATIONS.)

PACARAIMA, SIERRA, a mountain chain of South America, forming the boundary between Venezuela and Brazil. It divides the waters of the Orinoco and Essequibo on the N., from the Amazon and its affluents on the S., and extends E. and W. for about 200 miles, near the 4th degree of N. Lat. The height of the range towards the E. does not exceed 1500 feet; but Mount Pacaraima, near the western extremity, is estimated at 2000 feet high. The geological formation of the mountains is for the most part granite; and they are in general quite destitute of wood, forming a boundary between the dense forests on the N., and the vast grassy savannahs on the S.

PACCA, BARTOLOMEO, a Roman cardinal and statesman, was born of a noble family at Benevento in 1756. After studying in his native town, he repaired to Rome, and entering the church, was speedily recognised as a candidate for promotion. From 1786 to 1800 he held the office of papal nuncio at Cologne and Lisbon in succession; in 1801 a cardinal's hat was conferred upon him; and in 1808 Pius VII. made him his prime minister. The destiny of Pacca now became intimately connected with that of the supreme pontiff. He was the pope's accomplice in drawing up the bull which excommunicated Napoleon in 1809; he was consigned for this offence to the dungeon of Fenestrelle, at the same time that his master was imprisoned at Fontainbleau; and he shared in the honours of the pontiff's triumphal return to Rome in 1814. Such a severely-tried fidelity was rewarded by Pius VII. with ever-increasing confidence and regard. The cardinal continued to hold in succession several high civil offices till 1821, when he retired from public life. The rest of his days were chiefly devoted to literary pursuits. He died at Rome in 1844. The *Historical Memoirs* of Cardinal Pacca have been translated into English by Sir G. Head, in 2 vols. 8vo.

PACCHIAROTTO, JACOPO, one of the most eminent painters of the Sienese school, was born at Siena in the latter half of the fifteenth century. His style seems to have been formed on that of Pietro Perugino, and he must also have been a careful imitator of Raphael. Until 1535 his brush was chiefly employed in painting frescoes and altar-pieces for the churches of his native city. Then being obliged to escape to France on account of the active part he had taken in a conspiracy against the Sienese government, he began to assist Rosso. From this period there is no further trace of him. For a long time the works of Pacchiarotto were commonly ascribed to Perugino. Now, however, his name has been rescued from neglect; and although scarcely known beyond the limits of his native town, he is praised by critics for his skilful composition, and for the vivacity and grace of his heads and figures. The most famous of his pictures is "The Visit of St Catherine to the Body of St Agnes of Montepulciano," in the church of Santa Caterina in Siena. (Lanzi's *History of Painting.*)

PACE (*passus,* from *pando,* I extend), the unit of itinerary measure among the Romans, consisting of 5 Roman feet. The *passus,* or double step, was distinguished from the *gradus,* or single step, in not being the distance from heel to heel when the feet are at their ordinary extension in walking, but the distance from the point which the heel leaves to that in which it is again set down. A thousand of such paces formed the *mille passus,* or Roman mile. The word *passus* was sometimes applied to the distance formed by the extension of the arms in the same straight line (the Greek ὀργυιά), which accounts for Paucton's derivation of the word *à passis manibus,* instead of *à passis pedibus.* The Roman "pace" was equal to about 58·1 English inches, or 4·841$\dot{6}$ feet.

PACHECO, FRANCISCO, an eminent Spanish painter and historian of art, was born at Seville in 1571. His first lessons were received from Luis Fernandez; and from that time he was a busy and zealous student. He pored over the history of painting to learn the precepts and artistic usages of the ancient masters; the stray prints of Raphael that fell in his way were taken as models; and it became his custom never to execute a picture before making two or three studies of the heads and figures. The first engagements of the young artist were in decorative painting. In 1594 he adorned with figures and heraldic bearings the banners of the fleets of New Spain and the mainland; and in 1598 he executed in distemper some of the paintings on the monument erected on the occasion of the funeral honours of Philip II. By this time the peculiar style of Pacheco was beginning to appear and to be appreciated. His composition, though deficient in spirit and vigour, was simple and correct; his colouring, in spite of its harshness and dryness, was never glaringly unnatural; and if among the various provinces of art which he tried he did not shine in any, he made a respectable appearance in all. Accordingly, in the midst of other engagements, he was employed to paint some incidents from the life of St Raymond for the convent of Mercy in 1600, and the fable of Dædalus and Icarus for the palace of the Duke of Alcala in 1603. It was not long after this that the busiest part of Pacheco's life began. Opening an academy of painting, he was soon engrossed with numerous pupils. At the same time he was expending great labour and patience on his masterpiece, "The Last Judgment," an immense work, which was completed in 1612. Nor did his appointment in 1618 to the office of inquisitor of art, by giving him new employments, lessen his old. More commissions poured in upon him

than he could execute; and he was hired to paint many portraits, both in oil and crayons. In 1623 Pacheco had reached the acme of his reputation; and the latter years of his life began to pass by in the midst of peace and prosperity. Having accompanied his pupil and son-in-law Velasquez to Madrid in that same year, he spent the next two years in mingling with artists and men of letters, and enjoying the striking achievements and rising fortunes of his young relative. On his return to Seville he resigned himself to the pleasures and pursuits of literature. His brush was laid aside; his table was made the rendezvous for all the intellectual among the citizens; he found a refined amusement in the composition of occasional poems; and in 1649, after several years of congenial labour, he gave to the world the fruits of his extensive reading and ripe experience in his most important work, the treatise *On the Art of Painting*. His death took place in 1654.

The above-mentioned book of Pacheco, though pedantic in its style, prolix in its plan, and absurd in many of its speculations, contains much curious information, and is an invaluable authority on the history of Spanish art. It has never been reprinted, and is now exceedingly scarce. (Stirling's *Artists of Spain*.)

PACHETE, a district of British India, presidency of Bengal, lying between N. Lat. 22. 56. and 23. 54., E. Long. 85. 46. and 87. 10., is bounded on the N. by the districts of Ramgurh and Beerbhoom; E. by that of Bancoora; S. by those of Pooralia, Barabhoom, and Singhbhoom; and W. by that of Chota Nagpore. Length, from N.E. to S.W., 105 miles; breadth, 95 miles; area, 4792 square miles. The surface is occupied in many parts by hills of inconsiderable size, covered with forests and jungles; but in some places there are plains and valleys of small size, in which the soil is cultivated, rice being the principal crop raised. Much of the ground that now lies waste was formerly tilled; and its present neglected condition arises from the habit the people have of cultivating the land without intermission as long as it will yield anything, and then letting it lie fallow for a long time. The rocks of the district belong mostly to the primitive formation; and iron and coal are the principal minerals. The chief rivers are, the Damooda, Soobunreka, and Cossye, with their tributaries. The principal place in the district is Pachete, which can hardly be considered a town. It stands 6 miles from the right bank of the Damooda, 150 miles N.W. of Calcutta. Pop. (1855) of the district, along with that of Barabhoom, 772,340.

PACHOMIUS, or PACHUMIUS, the founder of the first organized monastic community, was born in the Thebaid in 292. He was educated in paganism; but the events of his early manhood began to lead him towards a new religious life. At the age of twenty he was impressed into the military service, and, in company with his fellow-recruits, was conveyed down the Nile in a transport. During a halt at Thebes some Christians, paying a kindly visit to the soldiers, explained to him their religious views and sentiments. He was converted, and forthwith made a vow to consecrate his days to the service of the true God. Accordingly, no sooner had an arduous campaign come to a close, than, hastening back to his native country, he received baptism, and began the great work of his career. It now became the aim of Pachomius to apply the principles which regulated the life of a single anchorite to the life of an organized society; or, in other words, to seek the salvation of men by withdrawing them from the depraving habits of the world, and subjecting them to a system of religious discipline. Accordingly, Tabenna, an island of the Nile in Upper Egypt, was selected for the site of the monastery; three disciples became the germ of the society; many more began to join; and the first specimen of a regular cloister was soon presented to the world. (See MONACHISM.) The founder himself, in the capacity of abbot, continued to govern and extend the influence of the rapidly-flourishing institution, till a pestilence cut him off, about 348. The extant works which pass under the name of Pachomius, and which consist of *Regulæ Monasticæ*, *Monita*, *Præcepta*, and *Literæ*, are contained in Galland's *Bibliotheca Patrum*, vol. iv., 1768.

PACIFIC OCEAN, sometimes called the SOUTH SEA (Fr. *Ocean-Austral*, *Mer-du-Sud*, or *Grand Ocean Pacifique;* Germ. *Südsee*, *Grosser-Ocean*, or *Stilles-Meer*), the largest of the great divisions of the water on the surface of the globe, stretches from the west coast of America to the east coasts of Asia and Australia, and from Behring's Strait on the N. to the Antarctic Circle on the S. It is separated from the other oceans by distinct boundaries on all sides but in the south, where it is divided from the Antarctic Ocean by the Antarctic Circle, from the Atlantic by an imaginary line drawn from Cape Horn to that circle, and from the Indian Ocean by a similar line, from South-West Cape in Tasmania to the same circle. It occupies nearly one-half of the entire surface of the earth, an area greater than that of all the dry land together; being estimated at more than 70,000,000 square miles. Its narrowest portion is in the north, where the continents of Asia and America, at Behring's Strait, approach within forty miles of each other; while further south the two continents recede to a great distance. Between the extremities of the peninsulas of Kamtschatka in Asia and Alashka in America the distance is more than 1200 miles. At the northern tropic the breadth of the ocean is about 8500 miles; at the equator it attains its greatest width, upwards of 10,000; and at the tropic of Capricorn it diminishes again to 8200 miles. The outline of the Pacific differs from that of the other great oceans in nothing more remarkably than in the absence of those great inland seas and gulfs, which in many parts of the others extend far into the heart of the continents. There are, indeed, especially along the Asiatic coasts, several portions of this ocean separated by peninsulas and chains of islands from the vast central expanse of water; but the Pacific has no inlets to be compared to the Mediterranean Sea, or Gulf of Mexico in the Atlantic, nor even to the Red Sea or Persian Gulf in the Indian Ocean. Throughout the whole of the eastern boundary of the Pacific the general character of the coast is high and bold, the lofty chains of the Andes and Rocky Mountains rising at no great distance from the sea. From Cape Horn northwards to the borders of Chili there extend a multitude of small islands, and the coast is indented by a number of bays and fiords. Farther north these islands cease, and the indentations, though numerous, are not of any size, as far as the northern extremity of South America. There the Gulf of Panama washes the inside of the curve formed by the Isthmus of Darien, 30 miles broad, which here is the only barrier between the Atlantic and Pacific oceans. Beyond this, the North American coast stretches in a north-westerly direction, without any remarkable features, as far as the long and narrow Gulf of California, the greatest of the inlets on the eastern shore of the Pacific, formed by the peninsula of the same name, which stretches southward parallel to the mainland. In the higher northern latitudes of this coast, as in the higher southern, the same features are discernible. Vancouver's Island is the most southerly of a series of islands similar to those that fringe the Patagonian coast; and in this region, as in that, the land is penetrated by numerous arms of the sea. With the peninsula of Alashka, stretching south-west from the American continent, a different character makes its appearance on the shores of the Pacific. Along the whole of the Asiatic coast there are ranges of islands, of greater or less size, which lie at a considerable distance from the land, and separate large portions of water from the rest of the ocean. The Aleutian Islands stretch westward from

Alashka, and terminate not far from Kamtschatka. North of them lies that portion of the Pacific called the Sea of Behring, or Kamtschatka Sea. The peninsula of Kamtschatka projects southwards from the Asiatic mainland, and, along with the Kurile Islands, that stretch to the south-west, forms the Sea of Okhotsk. The Sea of Japan lies between the Japan Islands and the continent; and the Yellow Sea is formed by the peninsula of Corea stretching to the south. Farther south, the Chinese Sea is separated from the Pacific by the island of Formosa and the Philippines; so that there is hardly any portion of the Asiatic coast that is not more or less protected from the Pacific by a barrier of islands. South of the Philippines the ocean washes the Moluccas and the north-east coasts of Papua, communicating by many channels with the Indian Ocean. The Solomon Islands and the New Hebrides inclose between them and the Australian coast a portion of the Pacific called the Coral Sea; but the east coast of Australia has not any remarkable capes or bays. The peculiar nature of the western shores of the Pacific seems to be due in a great measure to volcanic action; since all the chains of islands from Kamtschatka to New Zealand contain either active volcanoes, or evident traces of the former existence of such. Besides the islands already noticed lying near the shores of the ocean, the Pacific contains an immense number of others far removed from any continent. A vast extent of water, however, including the northern, eastern, and southern portions of the ocean, an area far exceeding that of the Atlantic, contains hardly any islands, the only important group being the Galapagos, which lie directly under the equator, 700 miles west of South America. In the central and western parts of the Pacific the islands are so thickly scattered, chiefly in groups, that they are sometimes considered a separate division of the globe, under the name of Polynesia. The Ladrone, Caroline, and Sandwich islands are the principal groups north of the equator; to the south, where the islands are more numerous, lie the Marquesas, Society, Navigator's, and Friendly islands, besides many others, singly and in groups. The large islands of New Zealand lie in the Southern Pacific, S.E. of Australia. Notwithstanding the vast area of the Pacific, and the extent of the coasts that it washes, but little of the river water of the world finds its way into this ocean. The great mountain range that divides the waters of the American continent is so near the shores of the Pacific, that not more than one-fifth of the area of the continent is watered by the affluents of this ocean. The only rivers of any size that enter the ocean from the east are the Rio Colorado, falling into the Gulf of California, and the Columbia River in Oregon, falling into the Pacific, to the south of Vancouver's Island. In Asia, there are three large rivers that fall into the Pacific—the Amoor, in Mongolia and Manchooria; and the Yantse-kiang and the Hoang-ho, in China; but the area watered by these, and by a few smaller streams, does not exceed one-seventh of the whole of Asia. There are no rivers of any size on the eastern coast of Australia, as the mountains that divide the waters approach there within a short distance of the sea. The Pacific, as well as the other great oceans of the world, is subject to regular winds; and these are less variable in their continuance and limits in this ocean than in the Atlantic. The N.E. trade-wind prevails throughout the ocean between the fifth and twenty-third degrees of north latitude. At different seasons, however, the northern limit varies from 20. to 27., and the southern from 1. to 11. The boundaries of the S.E. trade-wind are also different at different seasons, varying in the N. from 5. N. to 1. S. Lat., and in the S. from 20. to 25. S. Their mean extent is from the equator to 21. S. Between these two regions of the trade-winds there is a belt of about five degrees in breadth under the influence of varying winds and calms, and frequently visited by violent storms of lightning and rain. For a considerable distance from the coasts both of the American and also of the Asiatic and Australian mainlands the influence of the trade-winds is not felt, and the breezes in these parts are very irregular. The currents of the Pacific have not the same velocity or regularity as those of the Atlantic. There are, however, several worthy of notice, though comparatively little has been ascertained respecting them. South of the 33d or 34th degree of south latitude, a strong current flows from the S.W., with a velocity varying from 10 to 35 miles a day. Meeting the South American continent near the island of Chiloe, this stream divides into two parts, the one running round Cape Horn into the Atlantic, and the other, called the Peruvian current, flowing northwards along the coasts of Chili and Peru. This great body of cold water exercises a cooling influence on the climate of Peru, and extends as far north as Cape Blanco, where it turns to the west, and joins the great equatorial current moving from east to west in the southern region of the trade-winds. A south-western branch of this current washes the shores of Australia, and circles round between it and New Zealand. The region of the variable winds and calms is occupied by a current flowing from west to east; and the northern region of trade-winds, like the southern, has one which flows in an opposite direction. The latter, after being turned towards the north by the Philippine Islands, washes the coasts of Japan, and flows partly northward through Behring's Strait, and partly eastward to America, whence it circles round on its former course. The calm portions of the ocean in the centre of the revolving current in the North Pacific, and of the smaller one between Australia and New Zealand, form the principal whaling grounds in the Pacific. The tides of the Pacific are of small size. The Pacific Ocean was discovered in 1513 by Vasco Nuñez de Balboa, the Spanish governor of Darien, who crossed the isthmus, and obtained a view of this vast ocean. In 1521 Magellan entered it by rounding Cape Horn, and gave it the name of *Pacific*, on account of the calm weather he enjoyed after entering it, in contrast with the storms he had previously met with. This name, though not very appropriate, has continued to be that by which the ocean is most generally known. This vast expanse of water is not only very favourable to the commerce of the countries adjacent to it, but, by its productive fisheries, and its numberless islands, rich in many kinds of produce, adds in no small degree to the wealth of the world, and contributes to the necessities and to the luxuries of mankind.

PACIOLI, or PACIOLUS, LUCAS. See ALGEBRA.

PACTOLUS, a rivulet of Lydia, rises in Mount Timolus, and flows in a northerly direction into the Hermus. The particles of gold which it occasionally brought down in its mud gave it a celebrity in ancient fable. (See MIDAS.)

PACUVIUS, MARCUS, an old Roman dramatist, was the nephew of Ennius, and was born at Brundusium about 219 B.C. Repairing to Rome, he soon gained general esteem for his skill both in poetry and painting. One of his pictures was hung up in the temple of Hercules in the Forum Boarium at Rome, and many years afterwards elicited the commendation of the elder Pliny. But the best fruits of his genius were those tragedies which, for eloquence and refinement, rivalled all their predecessors on the Latin stage. Not content with merely translating, as was the custom with the early Roman dramatists, the plays of the Greeks, he exercised his own artistic ingenuity upon the borrowed materials, and even wrote purely original dramas upon the history of his own nation. The closing years of the long life of Pacuvius were spent in the retirement of his native town. There he was wont to entertain with generous friendship his successful rival Accius; and there he died, at an advanced age, about 129 B.C. The fragments of Pacu-

vius have been printed in Stephen's *Fragmenta Veterorum Poetarum*, Paris, 1564; and in Bothe's *Poetarum Latii Scenicorum Fragmenta*, Leipsic, 1834.

PADANG, a town on the west coast of the island of Sumatra, capital of a Dutch province of the same name; S. Lat. 0. 57., E. Long. 100. 20. It is built on a small river, in a valley bordered by wild and rocky hills, and consists of several distinct portions. The quarter which is farthest from the sea is chiefly inhabited by Chinese, who carry on an active traffic. It is very populous; and the river is navigated by many neat boats. Almost all the houses in this part of the town contain shops. The quarter inhabited by Malays, which lies near the mouth of the river, is poor and wretched, consisting of huts built of bamboos or the bark of trees. The European quarter is widely scattered over a plain to the N.W., and contains a few stone houses, but is chiefly built of wood and bamboos. Besides some small chapels, the principal building in the place is a large and well-arranged ball-room. Until recently, Padang was a very wretched place, but many new buildings and improvements have been recently made. It is the seat of the provincial governor, and of courts of law. In the vicinity there are extensive marshes, and the town has the reputation of being unhealthy. Pop. 10,000.

PADDINGTON, a parish in the county of Middlesex, England, forming a suburb of London to the N.W. It contains many fine streets, squares, and houses, and has places of worship belonging to the Church of England, the Baptists, Wesleyans, and other sects. The Great Western Railway has a large and convenient station here. The Paddington Canal communicates on the one hand by the Regent's Canal with the Thames, and on the other by the Grand Junction with the principal canals in England. Pop. 46,305.

PADERBORN, a town of Rhenish Prussia, government of Minden, province of Westphalia, stands at the source of the Pader, 50 miles S. by W. of Minden. It is an ancient town, surrounded by walls, through which there are five gates; and though pretty well built, it presents a gloomy appearance. The cathedral, completed in 1143, is a large building with two handsome portals; but among the monuments in the interior there are none of much interest. Of the other churches, that of St Bartholomew is remarkable for its architecture. There is a town-hall, a Roman Catholic theological college (occupying the place of a former university), several schools, convents, infirmary, and other establishments. Starch, leather, tobacco, beer, and brandy are made here; and there is some trade. Paderborn was made a bishopric by Charlemagne, being thus the oldest see in Westphalia. It was subsequently a member of the Hanseatic League. Pop. 11,028.

PADIHAM, a town of England, county of Lancaster, on the Calder, 4 miles W. of Burnley, and 15 E. of Preston. It is small and not very well built; containing a parish church with an old tower, and places of worship for Methodists, Baptists, and Unitarians, as well as several schools. In the vicinity there are coal mines; and the manufacture of cotton goods is actively carried on. Three annual fairs are held here. Pop. 4509.

PADILLA, JUAN LOPEZ DE, a famous Spanish patriot, was the eldest son of the commendator of Castile, and was born in Toledo towards the close of the fifteenth century. He grew up a brave, high-souled, and patriotic citizen, and only waited for an opportunity to play a distinguished part in the history of his country. This opportunity was soon brought about by the series of events which followed the accession of Charles V. to the crown of Spain. The entire administration during the absence of the king was placed in the hands of his Flemish favourites. A Flemish cardinal, Adrian of Utrecht, held the regency; Flemish courtiers sold the offices of state to the highest bidders; and Flemish place-hunters, after a short and lucrative sojourn, carried the wealth of Spain home to their own country. Incensed at this system of oppressive misrule, the rich and powerful cities of Castile laid before Charles, by the hands of their deputies, a long list of grievances; and finding that their claims were treated with silent neglect, they took up arms in vindication of their rights in 1522. It was then that Juan Lopez de Padilla appeared in the arena of history as the leader of the citizens of Toledo, and the most zealous promoter of the cause of the general insurrection. His first act was to form the deputies of the several towns into an association under the name of the "Holy Junta," which should take charge of the general interests of the people. Then proceeding at the head of a body of troops to Tordesillas, the residence of Joanna, the imbecile grandmother of the king, he succeeded in gaining admittance into the town, obtaining an audience of the queen, and exacting from her a sanction to do whatever should be necessary for the public welfare. His next enterprise was to strip the regent of the authority and ensigns of government. He marched to Tordesillas, the seat of the regency, seized upon the treasury books, the archives, and the seals of the kingdom, and left Adrian in the position of a private individual. At this juncture, however, the over-arrogant and injudicious measures of the Junta began to check the successes, and led to the ruin of Padilla. That body, by inserting among their plans of reformation a direct attack upon the power of the nobility, brought upon themselves the armed hostility of the warlike and chivalrous aristocracy of Spain. Not content with one indiscretion, they intrusted the defence and maintenance of their cause to Don Pedro de Giron, an individual who had no recommendation but his high birth. The consequence was, that the army of the nobility was allowed, without opposition, to attack and capture the important town of Tordesillas, and thus to inflict a deadly blow upon the success of the revolution. Again did Padilla assume the chief command, and, by the capture of Torrelobaton and other towns, maintain the cause of the Junta. But again did the Junta themselves, by granting a suspension of arms, betray that cause. At the end of the truce, Padilla found that so many of his soldiers had departed to their homes that he could not face the advancing enemy. He retreated towards Toro; the enemy overtook him on a piece of disadvantageous ground near Villalar on the 23d April 1522; and all his desperate measures and chivalrous valour could not prevent his fatigued and disheartened recruits from yielding before the dashing charge of the royalist cavalry. The hopes of the revolutionists were thus irretrievably ruined. Padilla, resolving not to survive the frustration of Spanish freedom, fought till the very last; but he was carried, captive and wounded, from the field to brave a public execution. On the next day, after addressing to his wife and his native city respectively, two letters full of tender devotion and triumphant heroism, he bravely laid down his life for his country.

PADILLA, *Doña Maria Pacheco de*, the wife of the preceding, proved herself a worthy mate to the leader of the forces of the "Holy Junta." During her husband's life she rendered a bold and active assistance to his warlike enterprise. On his death, she seized the standard of freedom as it fell from his lifeless hand; and although all the other insurgents were cowering in submission before the victorious royalists, she resolved to make Toledo the last citadel of liberty, and to defend it against the whole country. The commanding spirit of the heroine immediately brought into simultaneous action all the devices that could awaken sympathy for herself, or interest in behalf of Spain. She rallied the citizens around her, and kept their enthusiasm ever burning by constantly calling to their remembrance the deeds and death of her husband. She gave a sacred

Padron || Padua. character to the contest by using crucifixes instead of colours, and employing the revenues of the cathedral to defray expenses. She was also continually despatching letters and emissaries to implore assistance from the other cities of Castile, and the French general in Navarre. Thus did Doña Maria for several months, in the face of a powerful government, hold the city of Toledo. At length her influence, which could not be overcome by external force, began to be undermined by internal dissension. The troops, though victorious in several sallies, became hopeless of ultimate success; the mob grew impatient of the rigours of a blockade; the clergy took advantage of this disaffection to accuse the heroine of using witchcraft; and the noble woman was driven out by her ungrateful fellow-citizens. Yet Doña Maria made a becoming exit off the stage of history. Retreating into the citadel, she held out for four months longer; and not until she had been reduced to the last extremity did she retire into Portugal to pass the rest of her life. (Robertson's *Charles V.*)

PADRON, a town of Spain, province of Coruña, Galicia, on the Sar, near its confluence with the Ulla, 50 miles S. of Coruña. It contains a cathedral, a court-house, schools, and a prison. The body of St James is said to have landed at Padron, after miraculously sailing from Joppa in seven days. It was on this account a favourite resort of pilgrims. Pop. 6108, employed in farming and in the making of woollen and linen stuffs.

PADSTOW, a town of England, county of Cornwall, on the estuary of the Camel, 26 miles N. by E. of Falmouth. It is an old-fashioned fishing-town, and contains an old Gothic church, a custom-house, and some other public buildings. Ship-building is the business chiefly carried on. Corn, slate, and other minerals are exported. Pop. 2224.

PADUA, a province of the Lombardo-Venetian kingdom, in the government of Venice, is bounded on the N. by the province of Treviso, E. by that of Venice, S. by the Polesine, W. by Verona, and N.W. by Vicenza. It extends over 835 English square miles, and is divided into eight districts, containing 104 communes and 771 villages. Its population, which in 1834 was 286,800, in 1857 had risen to more than 318,000 persons. The land is an extensive plain, except on the S.W. side, where the volcanic group of the Euganean Hills rises. It is chiefly drained by the Brenta, the Musone, the Bacchiglione, and the Adige which skirts it on the S.; and has numerous canals, many of which are for irrigation, and some for navigation. The fertility of the soil is very great, and agriculture is well conducted; wine, wheat, maize, rice, oil, great variety of fruit, sheep, poultry, &c., are copiously produced. Hemp, flax, and silk are also extensively grown, and afford some employment to manufacturers, but they are chiefly exported in a raw state. The district of the Euganean Hills has numerous mineral springs; those of Abano, only 6 miles from Padua, are much resorted to by invalids.

PADUA (the anc. *Patavium*, Ital. *Padova*), the capital of the province of the same name, and one of the most ancient cities in Italy, is situated on the River Bacchiglione, in 45. 23. 40. N. Lat., and 11. 46. 38. E. Long. It stands in the midst of a garden-like plain, and is connected with the Lagunes by the Large Canal, with the River Adige by the Monselice Canal, and with Venice, Verona, and Milan by railway.

Legendary tradition attributed the foundation of *Patavium* to Antenor, after the fall of Troy:—

> "Antenor potuit, mediis elapsus Achivis,
> Illyricos penetrare sinus, atque intima tutus
> Regna Liburnorum, et fontes superare Timavi . . .
> Hic tamen ille urbem Patavi, sedesque locavit
> Teucrorum . . .
> . . Nunc placida compostus pace quiescit."
>
> *Æneid*, i. 243.

A large skeleton, grasping a sword in his bony hand, found in a marble sarcophagus discovered in 1274, was supposed to be that of the Trojan founder. *Patavium* was the capital of the Veneti, and at an early period was so flourishing that, according to Strabo, it could send an army of 120,000 men into the field. The Patavians were constantly at war with, and successfully withstood, the Cisalpine Gauls; and in 301 B.C. they also defeated Cleonymus the Lacedæmonian, who had unexpectedly landed at the mouth of the *Medoacus* (the modern Brenta), and attacked them. *Patavium* fell eventually under the power of Rome, though it seems to have retained a semblance of independence. At the time of Strabo it was still the first city in Upper Italy; but it was gradually eclipsed by Aquileia and Mediolanum. Its prosperity came suddenly to an end in 452, when it was taken and destroyed by Attila; and in 601 it was again taken and burnt to the ground by Agilulf, King of the Longobards. It rose, however, from its ashes; and in the tenth century it had already become, as it has continued ever since, one of the most important cities of Upper Italy. Padua.

In 1164 Padua formed, with Verona, Vicenza, and Treviso, a league for the protection of their liberties against Frederic I. Barbarossa; in 1167 it joined the great Lombard League; and by the peace of Constance in 1183 had at length its liberties acknowledged. In 1239 Eccelino da Romano made himself master of it, and after having practised unheard-of cruelties, in 1256 he was driven out and defeated by a crusade formed against him by most of the towns of Upper Italy. After a period of stormy independence, Padua in 1337 fell under the sway of the house of Carrara, who held it till the year 1405, when it was taken by the republic of Venice, with which, in 1797, it passed into the hands of Austria by the treaty of Campoformido.

The modern city contains upwards of 50,000 inhabitants, and is the see of a bishop, and the residence of the civil and criminal courts of first instance of the government of Venice. It is surrounded with walls and ditches, and defended by several bastions; it has many churches rich in works of art, many magnificent public buildings and old palaces, and several fine squares; but the streets are generally narrow, and most of the houses are supported by long rows of pointed arches. Its university, one of the oldest in Italy, enjoyed great celebrity as early as the beginning of the thirteenth century; and some of the greatest medical names in the sixteenth and seventeenth centuries, are among its professors. Galileo was for many years its professor of mathematics. There are five faculties—theology, law, medicine, philosophy, and mathematics, with 46 professorships, and from 1200 to 1800 students. In consequence of disturbances that took place on the 9th of February 1848, the university was closed on the 15th of that month by the Austrian military authority, and was not re-opened till 1850. Connected with the university, but at a distance from it, is a library of more than 100,000 vols. and 1500 MSS. The Episcopal and Benedictine libraries have more than 50,000 vols. each; and the Capitular library, of which Petrarch was one of the founders, 10,000 vols. and many MSS. There are connected with the university a botanical garden, founded by the Venetian senate in 1543, and containing some of the oldest specimens of exotic trees and plants in Europe; an astronomical observatory, founded in 1769; four clinical schools for medicine, surgery, midwifery, and diseases of the eye; and a veterinary and agricultural college. The Palazzo della Municipalità, or town-hall, erected in the twelfth century, is a vast building upon open arches, and contains a hall 267 feet long, and 89 in height and width. The chapel of St Maria dell' Arena, erected by the Scrovegno family, contains the most perfect and genuine frescoes by Giotto. The church of St Antonio is remarkable for the richness and beauty of its internal decorations. The Prato delle Valle is an irregular open space, in which are numerous statues of great men, chiefly natives of Padua.

Livy, and Thrasea Pætus, who was put to death by Nero, were born at Patavium; and modern Padua has been the birth-place of many distinguished philosophers and literary characters.

PADULA, a town of Naples, province of Principato Citra, 6 miles S.E. of La Sala. It contains several churches, and an hospital. Near the town are the remains of the once famous monastery of St Lorenzo, which was destroyed by the French. Pop. 9000.

PADUS, a river of ancient Italy. (See Po.)

PÆAN (παιάν, παιήων, and παιών), a hymn or song originally sung in honour of Apollo, and deriving its name, as is generally supposed, from Pæan, the god of healing, who, although alluded to in Homer as a distinct deity, was in all probability identical with Apollo. At all events, the name and office of healing after Homer's time were transferred to Apollo; he was invoked by the cry ἰήιε Παιάν (Æsch. *Ag.* 146; Soph. *Œd. Tyr.* 154); and in the choral chants sung to his honour the burden was ἰή or ἰώ Παιάν (Athenæus, xv., p. 696, &c.) The pæan was invariably a loud and joyous song expressive of hope and confidence. It was sung after any great deliverance, as a plague (*Il.* i. 473), or a battle (*Il.* xxii. 391). The Greek troops occasionally sung it as a war-song previous to an engagement (Xen. *Anab.* i. 8, § 17), which, if we may trust the statement of the scholiast on Thucydides, i. 50, was sacred to Ares or Mars; while that engaged in after the victory was addressed to Apollo. Other gods, and even mortals, had pæans occasionally sung to their honour. Thus the Lacedæmonians sang a pæan to Poseidon (Xen. *Hell.* iv. 7, § 4), and the Greek army to Zeus (Xen. *Anab.* iii. 2, § 9). Aratus sang pæans to the Macedonian Antigonus (Plat. *Cleom.* 16); a similar practice was employed at Delphi in honour of the Macedonian Craterus; and the Rhodians chanted the triumphant song to the praise of Ptolemæus I. of Egypt (*Athen.* xv., p. 696). (See Muller's *Dorians*, and *Hist. of Greek Literature.*)

PÆDO-BAPTISTS (from παις, *a child*, and βαπτιζω, *I baptize*), those who maintain that baptism should be administered during infancy. (See Baptism, and Baptists.)

PÆSTUM, or Posidonia, an ancient city of Lucania, was situated near the shore of the Pæstanus Sinus (*Gulf of Salerno*), about 5 miles S.E. from the mouth of the Silarus (*Sele*). The facts of its primitive history are very few. A colony of Greeks from Sybaris were probably its founders; it was originally called *Posidonia* ("the city of Poseidon or Neptune"); the magnificent remains of Grecian architecture that are still seen on its site indicate that it rose under its first inhabitants to opulence and splendour; and we infer that it passed, along with the neighbouring colonies, into the power of the Lucanians, and afterwards into that of the Romans. Not much greater is the historical importance of Pæstum during the period which followed its subjugation to Rome. During the second Punic war it had become one of the *Coloniæ Latinæ;* in the time of Strabo the stagnation of a rivulet that flowed past the walls had rendered the inhabitants unhealthy; during the period between the fifth and tenth centuries the town is noticed by ecclesiastical historians as the seat of a bishopric; and immediately afterwards it fell into ruin and desolation under the devastations of the Saracens. It was not until the eighteenth century that Pæstum attained its chief celebrity on account of its splendid architectural remains. These stand on a level uninhabited plain by the sea-shore, and are descried by the mariner from afar as he sails across the Gulf of Salerno. The principal structures are two hexastyle peripteral buildings, which, with the exception of the temple of Corinth, are considered to be the most severe and massive specimens of Doric architecture now extant. The finer and older of the two, which is known by the name of the temple of Neptune, is hypæthral or open to the sky, and occupies a space of 180 feet long by 80 wide. The other, differently called the temple of Vesta and of Ceres, is 108 feet in length by 48 in breadth. There is also another edifice which is supposed to have been a *basilica.* The remaining vestiges of the city consist of the ruins of an amphitheatre, many private houses, the walls and the gates, interspersed occasionally with the famous Pæstan roses, which were celebrated by Ovid, Virgil, and other Latin poets, and which still, in their wild state, flower twice a year, and shed a surpassing fragrance. (Swinburne's *Travels into the Two Sicilies* in 1777–78–79–80, in 2 vols. 4to, London, 1783–85; and Wilkins' *Magna Græcia*, fol., Cambridge, 1807.)

PAEZ, Pedro, a famous Spanish missionary, was born at Olmedo in New Castile in 1564. Having entered the Order of Jesus, he devoted himself to foreign missions, and repaired to Goa in 1588. His toils and sufferings, however, in the cause of proselytism did not commence until, in the course of a year, he was despatched along with a fellow-missionary to Abyssinia. The vessel was boarded by pirates off the coast of Arabia; he was doomed to hard labour during a captivity of seven years at Sana, the capital of Yemen; the next few years were spent in sojourning at Diu and Camboya; and it was only in 1603 that he reached his destination, the Abyssinian town of Massowa. Paez now set himself to spread Christianity throughout the country. Within a year he had made himself a proficient in Geez, the chief of the native dialects; had translated into that tongue the catechism of Marcos George; and had by these means been enabled to instruct in Christianity several Abyssinian children. This vigorous beginning soon led to important results. The success of the missionary was quickly known throughout the country; he was summoned to preach before the court, and so effectual was his sermon, that the king Za-Denghel professed himself a convert, and wrote to Europe for more missionaries. Even although this last act led to a civil war, and cost the king his life in 1604, the influence of Paez continued to increase. The successor to the throne, Melek-Seghed, recalled him to court, and presented him with a piece of ground at Gorgora, for the purpose of building a convent for his order, and a palace for himself. At length the king and the nobility were induced to abjure paganism and embrace Christianity. The missionary was rejoicing at the success of his labours, when he was seized with a fever, which brought his life to a close in 1612. Paez was the first European who visited the Abai, the supposed main branch of the Nile, although this honour was afterwards claimed by Bruce the traveller.

PAGAN, Blaise-Francois Comte de. (See Fortification, § *Rampart or Town Fortification.*)

PAGANINI, Nicolo, the most distinguished violinist of his time, was born at Genoa on the 18th of February 1784. His father was a small shopkeeper, and fond of music. Nicolo's musical talent manifesting itself in his infancy, his father resolved that it should receive proper cultivation; and therefore placed him under Costa, chief violinist at Genoa, with whom he studied the violin for six months with great assiduity. When twelve years old he performed in public, at Genoa, variations upon the air *La Carmagnola*, and was received with rapturous applause. His father then placed him under Alessandro Rolla, at Parma, and afterwards under Ghiretti, for instructions in instrumental composition. He laboured incessantly to perfect his violin-playing; and having accidentally met with Locatelli's ninth work, *L'Arte di Nuova Modulazione*, devoted himself to the study of that music, full of excessive difficulties and novel effects. It seems probable that he was also acquainted with that very extraordinary book, *Hortulus Chelicus*, &c., published in 1688 by the German violinist Walther, who held an office at the electoral court

of Mayence. In Walther's book we find very difficult passages in single and double stops; imitations of cocks and hens, of the nightingale, of the guitar, of the muffled harp, and of the bagpipe, &c., all for one violin. The writer of this article has a copy of that curious work, but wanting the last seven pages. In 1801 Paganini began his professional travels in Italy; and in 1827, at Rome, received from the Pope the Order of the Golden Spur. Between 1801 and 1805 he studied the guitar for nearly four years. He visited Germany in 1828, and gave his first concert at Paris on the 9th March 1831, and was everywhere heard with delight and astonishment. In the same year he went to London, and afterwards to Dublin and to Edinburgh. He returned to Italy in 1834, and purchased several properties, among others the Villa Gajona, near Parma. In 1836 he was unfortunately led by some speculators to join in the establishment of what was named the "Casino Paganini," in one of the fashionable quarters of Paris. Concerts were given there, but did not pay the expenses of the casino. Paganini was too ill to perform at these concerts. The creditors of the speculators raised a process against him, and he was condemned to pay 50,000 francs, and a warrant was issued for seizing his person. When that judgment was pronounced, he was dying at Nice, after having languished for some time in the south of France. He died on the 27th May, 1840, leaving considerable wealth to his only son. The peculiarities of Paganini's style have been carefully described in a work by Carl Guhr, chapel-master and director of the theatre in Frankfort-on-the-Maine. His great superiority as a violinist excited much envy and jealousy, and thence arose a number of absurd and atrocious calumnies directed against him, especially in Paris. He published the testimonies of Italian ambassadors and public functionaries in disproof of the accusations of his enemies, and reduced them to silence. Several spurious works were published under Paganini's name. The following is the list given by himself of his published works:—12 Caprices ou études pour violon seul, Op. 1, Milan, Ricordi; Paris, Pacini. 6 Sonates pour violon et guitare, Op. 2, ibid. 6 Idem, Op. 3, ibid. 3 Quatuors pour violon, alto, guitare, et violoncelle, Op. 4, Milan, Ricordi; Paris, Richault. 3 Idem, Op. 5, Milan, Ricordi. (G. F. G.)

PAGANISM is a general term applied to all forms of religious worship that differ from Christianity, Judaism, or Mohammedanism. It is thus equivalent to the term *heathenism*. The name pagans (*pagani*, villagers) was employed by the early Christian writers to designate those who, after Christianity became the prevailing religion of the towns, still adhered to the old Roman faith. (Isidorus, viii. 10; Cod. Theod. 16, 10.) These *pagani*, or occupants of the *pagi*, into which the country people of the Roman nation were divided as early as Servius Tullius (Dionys. iv. 15), or, according to some, of Numa (Dionys. ii. 76), and which continued down to the latest times of the Roman empire, were, by a necessity of their position, excluded from the superior influences of civilization known to the towns, and practised rites and celebrated festivals quite peculiar to themselves. The most famous was their annual festival of the *Paganalia*. Gradually the term *pagani* came to signify those who adhered to heathenish observances, or to the worship of false gods.

PAGGI, Giovanni Battista, an Italian artist, was born at Genoa in 1554. In addition to his passion for pictorial art, he attained early to a high celebrity in poetry, philosophy, and history. His first lessons in painting were received from Cambiaso; and he was gradually rising into notice in his art, when he was compelled to flee his country for homicide. He took up his residence in Florence, where he remained for twenty years, executing pictures of great merit. His works were characterized by dignity and nobleness, combined with a grace and delicacy which brought him occasionally into comparison with Baroccio, and even Coreggio. Witness his pictures in the church degli Angioli, in the cloister of S. Maria Novella, his stupendous "Transfiguration" in S. Marco, and his three pictures at Pavia. His reputation obtained his recal to Genoa in 1600, and he set to work to revive the declining art of his native town. Vandyck and Rubens had just visited that place, and left behind them some of their masterpieces, which provoked the competition of Paggi, and led to the production of his best works, the "Slaughter of the Innocents," and the two paintings at the church of S. Bartolommeo, executed in 1606. The better to further his design in reviving Geneose art, Paggi published in 1607 a useful compendium, designed for the use of young painters, entitled *Diffinizione o sia Divisione della Pittura*. This distinguished artist died at Genoa in 1627, leaving behind him a school of painters who did much to sustain the reputation of their master. (Lanzi, *History of Painting*, vol. v.)

PAGNINUS, Sanctes, a learned Italian Dominican, was born at Lucca in 1466. He was deeply and accurately skilled in Latin, Greek, Chaldaic, Arabic, and particularly Hebrew. After examining the vulgar translation of the Scriptures, he pronounced it very inaccurate, and undertook to make a new one from the Hebrew text. Under the patronage of Leo X., his version was printed at Lyons in 1528. This is the first modern translation of the Bible from the Hebrew text. Pagninus, however, is thought to have adhered with too great servility to the original, and thus to have rendered his translation obscure, barbarous, and full of solecisms. He also translated the New Testament from the Greek; and was author of a Hebrew Lexicon and a Hebrew Grammar. He died in 1536, at the age of seventy. Luther spoke of him and his translations in terms of the highest praise.

PAGO, an island of Austria, kingdom of Dalmatia, belonging to the circle of Zara, and lying to the N.N.W. of that town. It is of an irregular form, 37 miles in length by 6 in breadth; area, 106 square miles. The inhabitants are employed in fishing, making salt, tending sheep, and growing the vine. Pop. 5000. The town of Pago had, in 1846, 3078 inhabitants.

PAGODA (Pers. *pout ghod*, or *boot khoda*, house of an idol, or abode of God), is the name ordinarily applied by Europeans to eastern temples dedicated to the worship of idols. The pagodas of Hindustan and China usually consist of three subdivisions,—viz., a porch, a vestibule for the priests, and an inner sanctuary, where the principal idol (often called *pagoda*) is placed. Many of the Chinese temples, or *taas*, as they call them, are lofty, storeyed towers, gradually diminishing in height and width as they approach the summit, each storey ornamented by a projecting roof of glazed tiles, with bells suspended from the eaves. The taa or pagoda of Nanking, the most famous of the Chinese structures, will be found described under Nanking. The pagodas of Benares, Siam, Pegu, and Orissa are well known. (See Juggernath, and Architecture, § *On Indian Structures*.)

The term *pagoda* is also applied to a gold or silver coin current in Hindustan, value from 8s. to 9s., and probably deriving its name from the images of the gods originally stamped upon it.

PAHANG, a territory of the Malay Peninsula, lying between N. Lat. 20. 10. and 4. 15., is bounded on the N. by Tringanu, E. by the Chinese Sea, S. by Johore, and W. by Salengore. The coast, which is skirted by numerous small islands, is in some places low and swampy, but in others presents a bold rocky front to the sea. The interior is little known. Along the western frontier runs a chain of hills, sending several small rivers to the sea. The country contains gold and tin, the latter of which is exported in

large quantities. The rajah of Pahang, though nominally subject to the sovereign of Johore, is virtually independent. Population variously estimated from 50,000 to 16,000. The town of Pahang stands at the mouth of a river of the same name, 135 miles N.E. of Malacca. It is chiefly built of wood and bamboos, and has 8000 or 10,000 inhabitants.

PAHLUNPORE, a small state of British India, under the superintendence of the presidency of Bombay, lies between N. Lat. 23. 57. and 24. 41., and between E. Lon. 71. 51. and 72. 45. It is bounded on the N. by the Rajpoot principality of Serohee, E. by Keyralla and Daunta, S. by the district of Puttun, and W. by Thurraid; area, 1850 square miles. The north-east part of the country is occupied with mountains, from which the rivers Bunass, Surruswuttee, and Numrodakee take their origin, and flow into the Runn. The reigning family of Pahlunpore is of Afghan origin, and received this country from the Emperor of Delhi towards the end of the seventeenth century. This state being in 1813 in a condition of anarchy and civil war, the British government interfered to restore order. An arrangement was accordingly made that Futteh Khan, the rightful heir, should reign under the guardianship, during his minority, of his uncle, Shumshere Khan. But the latter, having failed to fulfil his agreement, was in 1817 deprived of his authority; and Futteh Khan finding himself unable to manage his affairs, a British agent was sent to superintend the finances, but with no power to interfere, except by recommendation, with the internal affairs of the state. No tribute is paid to the British beyond the expenses of this agent, but L.5000 is paid to the Guicowar. The average annual revenue is little less than L.30,000; the expenditure, exclusive of the above tribute, L.20,000. Pop. 130,000. The town of Pahlunpore stands on the road between Neemuch and Deessa, 80 miles N. of Ahmedabad. It is walled, and has some trade and manufactures. Pop. estimated at 30,000.

PAIMBŒUF, a town of France, capital of an arrondissement of the same name, in the department of Loire-Inférieure, stands on the left bank of the Loire, here 3 miles broad, 24 miles W. of Nantes. The river is lined with quays; and the town contains dockyards, a customhouse, school of navigation, and has a convenient harbour for the largest vessels, formed by a mole 214 feet long. The people are employed in ship-building, making bricks, tiles, canvas, cordage, marine stores, and other articles; as well as in the fisheries and the coasting trade. Steamers ply daily to Nantes; and large vessels generally discharge their cargoes into lighters here. Pop. (1856) 4135.

PAINE, Thomas, a notorious political and deistical writer, was the son of a Quaker, and was born at Thetford in Norfolk in 1737. The early part of his career was marked by a restless love of vicissitude. A scanty education had scarcely been received, and his father's trade of staymaking had scarcely been learned, when he went out into the world to seek his fortune. He shifted ceaselessly from town to town; divorced one wife after burying another; and plied, according as necessity compelled him, the various vocations of staymaker, sailor, exciseman, schoolmaster, grocer, and tobacconist. In 1774 he was a garret writer in London; and in the following year he arrived in Philadelphia, a literary adventurer, with a letter of introduction from Dr Franklin. Paine now began a new era of his life by appearing upon the field of political controversy as a defender of the rights of the American colonies. For engaging in such a contest with spirit and success he was well qualified both by disposition and training. His weapons were a rough, ready, and vigorous intellect; a coarse and merciless wit; a stock of impudence with which he could out-brave all the claims of propriety; and a supply of venomous ill-humour into which he could dip all the darts of his satire. He begun the attack in January 1775 by publishing *Common Sense*, a pamphlet which boldly sounded the note of rebellion, and summoned the colonies to prepare for separating themselves from the mother country. The stirring effect which this work produced, and the unprecedented popularity which it acquired, fairly involved the author in the contest. As the great struggle for independence proceeded, he found himself called upon, in a series of papers called *The Crisis*, to console the Americans for any check they might have encountered, and to ridicule the British for any deed they might have done. All these services were rewarded during the continuation of the war by the office of clerk to the Committee for Foreign Affairs, and at the conclusion of hostilities by a donation of 3000 dollars and an estate near New Rochelle. The peace which followed between America and Great Britain was not the proper element for a spirit that revelled in revolution and misrule; and accordingly, in no long time, Paine had begun to look towards a new sphere of action. Repairing to Europe in 1787 with the professed purpose of exhibiting a model of an iron bridge, he commenced to incite and inflame the insurrectionary feeling that was secretly growing in England, and openly venting itself in France. For some time he continued to pass between the two countries like a firebrand, carrying the flame of rebellion from the one to the other. At length, in 1792, his arraignment by the British government on account of his seditious publication *The Rights of Man*, forced him to flee to France, and to play an active part in the bloody and undiscriminating revolution which was raging there. Barely escaping the guillotine on one occasion, and suffering imprisonment on another, he was for several years a member of the French National Convention. He brought his destructive labours to a climax in 1794–5 by attempting, in his celebrated book *The Age of Reason*, to overthrow Christianity, and introduce into religion the anarchy and disorder of his political creed. From this time the influence and happiness of Paine began simultaneously to decline. During the remainder of his stay in France he was fast falling into disrepute, and yet he was afraid to set sail for the United States lest he should be seized by British cruisers. On his return to America in 1802, the decay of his fortunes became still more apparent. His profane attacks upon religion had alienated many of his political friends; his growing worthlessness cooled the attachment of the few that were left; and his insolent resistance of all interference, repelled those strangers who would willingly have done him service. The wretched old man was thus driven to throw off all regard for his fellow-men, and consequently all respect for himself. Thenceforth he lived alone in lodgings, abandoning himself to sordid sloth, and deadening the pangs of his awakening conscience, and the uneasiness of his diseased body, with the stupor of intoxication. His miserable condition was terminated only by his death in June 1809. (Cheetham's *Life of Paine.*)

PAINGTON, a town of England, county of Devon, at the head of Torbay, 6 miles N.N.E. of Dartmouth. The parish church is an old building, containing a curious stone pulpit. There are several other places of worship, schools, and a reading-room. Large quantities of cider are made in the vicinity. Pop. of parish, 2746.

PAINSWICK, a town of England, county of Gloucester, stands on the southern slope of Sponebed Hill, near the Slade Water, 6 miles S. of Gloucester. It is irregularly built, and has an old church, several other places of worship, schools, and benevolent institutions. A large number of the inhabitants are employed in the manufacture of woollen cloth; and freestone quarries are worked in the vicinity. Many Roman coins and antiquities have been found in the neighbourhood. Pop. of parish, 3464.

PAINTING.

Painting.

Definition.

PAINTING is the art of conveying thought by the imitation of things through the medium of form and colour, light and shadow. Colour, and light and shadow, can by themselves do little more than excite sensations of harmony and sentiment, independently of action, passion, or story; but if founded upon form, thoughts become clear, expressions of passion intelligible, and actions, gestures, and motions of the human frame defined and decided. *Form* therefore is the basis of painting, sculpture, architecture, and design of every description.

Any school of painting, therefore, which is established upon a principle different from this, or which makes the subordinate parts of colour, light, and shadow the principal law of its practice instead of a component part, is in opposition to the most celebrated schools in the world; for the most eminent both in Greece and in Italy, were indebted for their celebrity and renown to the strict observance of the doctrine here enunciated. In Greece, the schools of Sicyon, Corinth, Athens and Rhodes, and in Italy, those of Pisa, Florence, Rome, and Bologna, were the most important, the most useful, and the most intellectual; and in all these *form* constituted the great and fundamental law of their practice. But in Venice, colour took the lead; it predominated too in Holland and Flanders; and it has always reigned, to the sacrifice of common sense, in Britain. Yet for sound and philosophical views of art, as a vehicle of passion or of moral national influence, neither of these schools can be referred to, with the same conviction or confidence with which all nations can refer to the former great sources of sense, principle, and genius.

Origin of painting.

In what country Painting first originated, is nearly as difficult to discover, as it is to find a country where it never existed at all. Design, the basis of painting, must have begun with the very first instrument of necessity which man required. The origin of any art, science, or discovery, is not so much owing to the particular accident which happened to the individual concerned, as to the intellectual adaptation of that individual to receive impressions of a peculiar nature from the particular circumstance which occurred. Thus whether Music was invented by the man, who, listening to the sound of an anvil, instantly composed notes; or whether Painting was discovered by the lovely girl, who, watching the shadow of her lover, as he sat silent at the prospect of parting, traced it upon the wall as a memento of their mutual affection; whether it originated with Philocles in Egypt, or Cleanthes in Corinth, or long before Egypt or Greece were habitable; the *principle* is the same. Without an inherent susceptibility to the impressions of sound, in preference to all other impressions, in the man, or an inherent susceptibility to the impressions of form equally intense in the girl, the intellectual faculties of either would have never been excited to compose notes, or to define figures. The art originated with the first man who was born with such acute sensibility to the beauty of form, colour, and light and shadow, as to be impelled to convey his thoughts by positive imitation.

When the Spaniards landed in South America, the mode by which the natives conveyed intelligence of their arrival to king Montezuma was by painting the clothes of the strangers, their looks, their dress, and their ships. This certainly must have been the most ancient, because the most simple and obvious mode in the world of conveying thought, after oral communication. But independently of all theory, there cannot be a doubt of the extreme antiquity of painting. The walls of Babylon were painted after nature with different species of animals, hunting expeditions, and combats. Semiramis was represented on horseback striking a leopard with a dart, and her husband Ninus wounding a lion. "And I went in and saw, and behold every form of creeping things, and abominable beasts, and all the idols of the house of Israel, *pourtrayed on the wall round about.*" (Ezek. viii. 18.) "She saw men *pourtrayed upon the wall*, the images of the Chaldeans *pourtrayed in vermilion*, girded with girdles upon their loins, exceeding in *dyed attire* upon their heads, all of them princes to look at, after the manner of the *Babylonians and Chaldeans.*" (chap. xxiii. 14, 15.) It is inferred from a passage of Diodorus Siculus, that these figures were painted first on the brick before burning, and then vitrified by fire.[1] But before this was done, experience must have been acquired of the liability to decay of painting upon external walls; and considering, too, that great statues were erected in Babylon, the arts must have existed amongst the Babylonians long before the period here referred to.

Antiquity of art in Ethiopia.

But a great revolution has taken place in our ideas on this subject, from the decyphering of hieroglyphics, and we are now assured of the extreme antiquity of art, in ages hitherto deemed almost entirely fabulous. From Asiatic art we have been accustomed to turn to that of the Egyptians; but it is no longer considered as a matter of speculation that the Ethiopians preceded the latter in knowledge, and that from this ancient people the Egyptians received gradually a knowledge of art. The course of civilisation probably descended from Ethiopia to Egypt; and yet we have evidence of the existence of Egyptian painting and sculpture more than eighteen centuries before Christ, and even then the arts were in the highest condition that the Egyptian school ever attained. From the most ancient records of the Jewish and Greek historians, in which Egyptian and Ethiopian monarchs are mentioned, and their actions narrated, we can now turn to corresponding traces of their existence and exploits commemorated upon the durable materials of the temples, tombs, and palaces which still remain. When therefore it is found that this method of interpreting hieroglyphics has proved to be correct, in all that we know of the Cæsars and the Ptolemies, or see casually alluded to respecting the Pharaohs, we have no right at all to dispute the truth of the same mode of interpretation when it indicates a still higher antiquity, though we have not the means of confirming it by collateral reference. Eighty miles above Dongola, Lord Prudhoe discovered the remains of a magnificent city, which he conceives to have been the capital of Tirhakah mentioned in the Bible; and amongst these ruins he observed two nobly executed lions, specimens of Ethiopian skill. On the shoulders of one is the name of Amenoph III., who was called Memnon by Greek historians. The style and execution of these great works are evidence of the talent of this people.[2] It is now certain that as early as the nineteenth century before Christ, the walls and temples of Thebes were decorated with paintings and sculpture, commemorating personal and historical events; and certainly in comparing the designs on these temples with those of a later period, we must conclude that the Egyptian school of painting never exceeded their merit.[3]

The conclusion to be drawn is, that at this time the Egyp-

tian priesthood had not interfered with art or artists; but that the painters were left freely to commemorate the great actions of their employers, to study nature, and to do as they liked. Many of these actions are delineated in a natural manner, and there is a great deal of dignity in the figure of the hero; the sea fights are also well grouped, and there are many of the Trajan-column figures, and not more gross perspective is visible. The colour is a mere illumination, and the composition as a whole infantine; but there is proportion, and not absolute ignorance of the component parts.[1] After this period, art became a mere tool in the hands of the priests; and as the law compelled the son to follow the profession of his father, it may be supposed that painting degenerated into the mere fac-simile of prescribed forms of gods, goddesses, and men, and that in the time of the Ptolemies it was little better than an illuminated hieroglyphic.

Character of Egyptian design.

The Egyptians appear to have done every thing with reference to form. Their painting was at best but coloured sculpture. They seem to have been aware of the mortality of colours, and to have said, "As colours must go, let us cut out the designs in stone, so that at least form may remain in our granite sculpture, and defy every thing but the convulsion of the earth." First the designer drew the outline in red, then the master artist corrected it, then the sculptor cut it, then the painter coloured it, gods blue, goddesses yellow, men red, and draperies green and black; and such is the extreme dryness of the climate, that a traveller says, he saw in Nubia, a bas-relief half cut, with the red outline left for the rest, and that he wetted his finger and put it up, and immediately obliterated a part of the red chalk.

The Egyptians would seem to have been a severe people, as hard as their own granite.[2] They had an awful feeling of respect for the wisdom of their ancestors; they hated reform; no physician dared to prescribe a new medicine, and no painter dared to invent a new thought. Plato says, that the pictures of his day in Egypt were just the same as from ages immemorial;[3] and, according to Winkelman, another cause of their inferiority in painting, was the little estimation in which painters were held, and their extreme ignorance. Not a single painter of eminence has reached us, and but one sculptor, viz. Memnon, author of three statues at the entrance of the great temple at Thebes. In the knowledge of the figure it is impossible they could be great; for there is proof that they dared not touch the dead body for dissection, and even the embalmers risked their lives from the hatred of the populace.

Winkelman divides Egyptian design into three periods: First, from the earliest times to the conquest of Cambyses; secondly, from the conquest of Cambyses to the subjugation of the Persian and the establishment of the Greek dynasty in Egypt; and, thirdly, from that period to the time of Hadrian.[4] When the paintings at Thebes were executed is not known. But they were upon the walls at the expulsion of the Shepherd Kings,[5] and this was the first period of their art, and before Moses. The Egyptians never, in either art, reached the power of making men, as Aristotle said of Polygnotus, *better* than they were; in other words, they never attained the true ideal beauty, founded on nature, yet above it. Their figures are debased transcripts of what they had about them, and therefore, so far authentic as to character. The Egyptian female heads are far from displeasing; they have a sleepy voluptuous eye,[6] a full and pleasant mouth, high cheek bones, dark brows, and there is something by no means disagreeable in the silent lazy look of their expression. But the very want of ideal beauty gives an assurance that the figures are Egyptian nature, and that every habit, public, private, civil and religious, is laid open to us, by the wonderful discoveries of Belzoni and his followers: it is almost as impossible now for an artist to be incorrect in painting an Egyptian subject, as it would be to err in painting a British one. In a tomb laid open by Belzoni, the characters of the procession were admirably distinguished; the Jew, the Egyptian, the Negro, and the Chaldæan, were as little liable to be confounded as if they had been before us. In their sculpture, however, there is more of science than in their painting. Sculpture was practised by the priesthood, and sculptors were called sacred stonecutters. The great head of Memnon in the British Museum is beautifully cut, the nose and mouth especially; and, considering its remote antiquity, it is really a great wonder.

Upon the whole, it is impossible to believe that the art of painting, amongst other nations, owed much to the Egyptians; they had no colour, and no light and shadow, but only some form, some expression, and some character. The groups of the ruins of Elythia shew a great deal of nature and simplicity; the animals are varied, and the cows are lowing and gamboling; yet it is after all but childish work, and as the paintings at Thebes are the best, those of Elythia have not much to boast of.

Whether the Greeks owe their beginnings to Egypt, is more than doubtful, from the simple fact of the early Greek painters using *no blue*, whilst it was the constant practice of Egyptian painters to use blue in every thing.[7] Athens was founded by an Egyptian colony, and painters might be amongst the emigrants, as well as masons and sculptors; yet in the early state of things, painters were not an article of necessity, and it is problematical if in this alleged emigration, there were any persons of that class. The beginning of art was the same in all nations. They might improve each other; but we do not believe that painting was ever originally brought into one nation by another, or that there ever existed any, where it has not always been more or less known from the remotest period of their history.

State of art amongst the Hebrews and other Eastern nations.

After Ethiopian and Egyptian art, that of the Hebrew people must next be examined. That they had sculptors and chasers, is evident; but it is not so certain that painting was practised. Though the cunning work of the curtains in Exodus means tapestry, and for any cunning work of the kind, designs coloured must have been executed; yet there is no proof in any part of the Bible that painting as an art was ever practised by them; and even the designs alluded to were exclusively applied for the purposes of religion. "Moreover, thou shalt make the tabernacle with ten curtains of fine twined linen, with blue, and purple, and scarlet; with cherubim of cunning work shalt thou make them." (Exodus xxvi. 1.) "And the Lord spake unto Moses, saying, See, I have called by name Bezaleel the son of Uri, the son of Hur, of the tribe of Judah; and I have filled him with the spirit of God, in wisdom, and in understanding, and in knowledge, and in all manner of workmanship, to devise cunning works, to work in gold, and in silver, and in brass, and in cutting of stones, to set them, and in carving of timber, to work in all *manner of workmanship*." (Exod. xxxi. 1—5.) Yet when Solomon wanted artists, he sent to Tyre, which is presumptive evidence of a deficiency of skill at Jerusalem. No allusion is made to the existence of the art of painting amongst the Hebrews; yet it is hardly possible to suppose a people working in stone, and silver, and gold, and timber, designing and weaving a cunning work of cherubims on curtains and bor-

[7] Col. Leake says there is a remnant of blue on the temple of Theseus; but that may be as applied to architecture. The question is, whether the great painters used it in their art. Pliny says no, and Quintilian confirms him by applying to them the expression *simplex color*. No colour is *simplex* where pure blue is used.

ders for garments, and having been so long amongst the Egyptians, to have been ignorant of painting; but it is the opinion of one of the greatest living authorities in the church, that the representation of any object by painting was not permitted to the Hebrews.

With respect to the painting of the Phœnicians, Persians, Indians, and Chinese, it was in the earliest ages, and has ever since been, miserable and wretched. Although the Indians and Persians have always been celebrated for their tapestry, yet it is more for the excellence of the material than the purity of their designs. You may know a tiger from an elephant, though scarcely from a monkey, in their tapestry, shawls, and carpets; but in their utter ignorance of the naked figure, their long, barbarous, and cumbersome garments, and their want of science, are so grossly palpable, that they have never been, and never will be, referred to by any nation as authority in design. In their coins, however, the ancient Phœnicians shewed more knowledge of the form than the Persians, the Chinese, or the Indians.

Etruscan art.

From the painting of these Eastern nations, we may now justifiably approach a people, whose origin, history, and science, have puzzled historians more than perhaps the Atlantides themselves. Who the Etruscans were nobody knows; but all agree that they were not aborigines, and this is establishing something. Yet it can scarcely be questioned that in their most remote, as well as their more refined periods, they were indebted for their arts, their language, and their religion, principally to the Grecians. The time when the Etruscans had commercial relations with Egypt and Greece, is hardly known;[1] but as their early style of art is a little Egyptian and their subjects Grecian, they were no doubt connected with both, even before the Greeks had settled in Italy. It is not yet decided where they came from, and who they were, and if one consults all who have written on the subject from Herodotus to M. Raoul-Rochette, he is likely to be as open to a new theory as when he began. Their early works prove nothing. These are like the early works of almost all barbarous nations. The gods of the Etruscans are, in point of art, the gods of the Peruvians, the Sandwich Islanders, or the Esquimaux. Idols are idols, in early nations all over the world; and the bandy-legged Apollos, squinting Pans, and *Dii indigenetes*, sixteen heads high, of this mysterious people, would do as well for any of the gods of the South Seas, as the early barbarians of the Mediterranean.[2] When commerce brought them in contact with Greece and Egypt, traces of the art of both nations become apparent; but this is no evidence that they came exclusively from one nation or from the other.

Winkelman is a person of great genius, and always touches art as if he saw the whole ground. He divides Etruscan art into three epochs, Heyne into five;[3] he goes to leading points, Heyne enters into details. The first epoch was gross; the second exhibited traces of Greek or Pelasgic art; the third had a taint of Egyptian; the fourth was better; the fifth produced ideal beauty and Greek mythology; and this completes the period till decay. Campania was colonized 801 B.C.; but the Eubœans had founded Cuma 1550 B.C. This neighbourhood brought the Etruscans in contact with Greek art, when about the ninth or eleventh Olympiad Greek colonies were established in Sicily; and the intercourse being reciprocal and complete, it cannot be wondered, that the more ignorant of the two nations became fascinated and inoculated by the superior one, and thus rendered Etruscan so like Greek art, that it has ever since produced doubt and confusion.

According to Pliny, the arrival of Demaratus with Cleanthes from Corinth, first brought art into Etruria about 650 B.C.; yet, he says, there were beautiful pictures at Ardea and Lanuvium, which were older than Rome, and Rome was founded 754 B.C. Heyne says, that before Rome was built, casting of metal, sculpture, and painting existed in Etruria anterior to any connection of the Etruscans with Greece; according to Winkelman the Etruscans were advanced in art before the Greeks, and it was a tradition of the remote ages, that Dædalus flying from Minos settled in Etruria and first sowed the seeds of design. When Etruria became a Roman province, Marcus Flavius Flaccus besieged Volsinium, the etymological meaning of which is, "The town of artists," and brought away two thousand statues from that city alone. An able writer in the "Newcastle Transactions" contends, that it is doubtful if the Etruscans had any art before the arrival of the Greeks.[4] No historian of this nation has reached us; their inscriptions are not yet thoroughly decyphered; and as the Romans destroyed every monument of surrounding nations, there is no fixing their antiquity. It is clear, however, that painting flourished in Italy before it did in Greece; such at least is the opinion of Tiraboschi.[5] Pliny says nothing about it before the 18th Olympiad in Greece, whereas in the 16th there were paintings in the above towns in Italy, and works too shewing great refinement; which the Romans admired in their days of splendour, and which their emperors wished to remove, surrounded as they were by the finest productions of Grecian art. Their civil and religious rites not being the same as the Egyptians, and there being no traces of embalming, it may thence be concluded that they were not of Egyptian origin.

All hopes of discovering any of their paintings, any important work which should give us evidence of their talents in art, were given up, till in 1760 Pacciaudi discovered at Tarquinia, tombs decorated with designs; and in 1837 fac-similes of pictural decorations of other tombs were exhibited in London, with the monumental statues themselves, and in parts were extremely beautiful in taste, design, expression, and drapery. The extremities were correctly and sweetly drawn; and the expression and character of the head, which were very interesting, would not have disgraced any period of Greek or Italian design, though they would not have honoured the finest. It is impossible to judge of the colour of the Etruscan school from these specimens, or from the vases called Etruscan. Fresco, stucco, or distemper are adapted neither for depth nor for tone; oil or encaustic is the only vehicle fit for harmony, and oil or encaustic was never practised by them. With respect to the painted vases called Etruscan, because they are found in Etruria, we might just as well assert, if one discovered in the middle of Yorkshire, a mass of china, that it must be of English manufacture because it was found in Yorkshire. After the Greeks had settled in the south, their vases might be and no doubt were an article of commerce; of course they were imitated, but surely the design and origin are wholly Grecian, whatever the Etruscans might after long intercourse do in the way of imitation. The principles of design and proportion in these beautiful productions, are the same as in the finest works of Greek sculpture, with an occasional but trifling variation. Raffaelle himself could not have exceeded the purity of form expressed by line, in drapery or figure. In the finest vases the artists seem to have been perfect masters of the figure, and to have gone right round with the stylus, till the contour of the part was completely expressed. Nor is there any thing wonderful in this, considering the manner in which Greek artists and manufacturers began, proceeded, and concluded their studies. According to Plato, a perfect mastery of the forms

[1] B.C. 1556. [2] See Gorius. [3] See Heyne's Notes on Winkelman, vol. i.
[4] This is a most able article, and the reader is referred to it for more extensive information on the Etruscans.
[5] *Storia della Letteratura Italiana.*

of man and animal was the basis of all instruction in design.

We have thus brought down the history of the art to a period, when our information, though imperfect, is more certain; but we can never sufficiently estimate the loss of all the ancient treatises on art, though we ought to be very grateful for what we possess in Plato and Aristotle, Pliny and Quintilian, and other ancient writers, Greek and Roman, down to the middle ages, and till the subject was taken up by Vasari and Lanzi.[1] The continued existence of this glorious art, can always be proved, more or less subject of course, like every thing human, to those alternations of splendour and calamity, triumph and misfortune, which are the lot of every thing here below.

Greek school of art.

The superiority of the Greeks in art is always attributed to the secondary causes of climate and government, forgetting the one important requisite, without which the influence of the most genial climate, or the patronage of the most perfect government could avail little; we mean natural and inherent genius. If the Athenians, the Rhodians, the Corinthians, and the Sicyonians owed their excellence in art to the climate, why did not the same climate produce equal perfection in the Spartans and Arcadians? If climate be the secret, why are not all people under the same latitude equally gifted and equally refined? Climate may be more or less favourable to intellectual development, but is never the cause of its existence. Government may elicit genius by fostering and reward, but can never create it. All the lamentation about the climate of England, Scotland, or Flanders, did not prevent Hogarth's appearance in the first, Wilkie's in the second, or Rubens' in the last of these countries; nor could all the beauty of climate in Greece or Italy, ever have made Mengs a Raffaelle, or David the Titian of modern times. It would be absurd to deny altogether the influence of climate in the extremes. It is not impossible but that genius might melt to indolence under the line, or freeze to apathy within the arctic circle; but even genius there would assert its superiority in something or in some way. What we contend for is, that Winkelman's theory of limiting the gifts of God, intellectual or corporeal, to latitude or longitude, is not borne out by facts, the great test of all theoretical principles.

The Greeks were idolaters, and their love of beauty was a principle of their religion. The more beautiful a face or form could be rendered in painting or sculpture, the better chance had the artist of the blessing of the gods here, and their immortal rewards hereafter. As beauty was so much prized by this highly-endowed people, those who were gifted with it became ambitious of making it known to great artists, and by them to the world. Artists fixed the fame of beauty in man or woman, and even children who gave promise of being beautiful were allowed to contest for a prize, and the child who won it had a statue erected to him. Many people were complimented by being named from the beauty of any particular part, and Winkelman quotes an instance, where one was called *Χαριτοβλεφαρος*, that is, "having eyelids where the graces sat." There were games instituted near the River Alphæus, where prizes were adjudged to the most beautiful; and the Lacedæmonian women in their bed-rooms kept continually before their eyes the finest statues. Still, this admiration of beauty was but a secondary cause; for though the Lacedæmonians showed this love of beauty, they did not produce great artists. The Greeks had a strong sensibility to beauty and an intense acuteness of understanding. Every artist was a philosopher, and every philosopher relished art, and understood it. The artists began by the study of geometry and of form; they analyzed the peculiarities of the form of man, by contrasting it with that of the brutes, and they settled the principles of beauty in that form and figure. The philosophers recommended to all classes the study of art, as a refined mode of elevating their perception of beauty; and the government seconded the recommendation of the philosophers. The priests found the religious feeling rendered more acute by painting and sculpture; and the authorities discovered, that the emotions of patriotism were doubled by the commemoration of great national events, in temples and in public halls. Now, add climate as adapted for such productions and their preservation, and genius, the gift of God, as the first cause, and no one surely need wonder that all these causes mutually acting on each other produced the miracles of perfection in art which the world has gazed at ever since with an incredulous and bewildered astonishment.

The passion for the beautiful in poetry, painting, music, and nature, led them to abhor the bloody amusements of the Romans. To contest for glory by pictures, poems, or music, to race for the prize of swiftness, or wrestle for the crown of strength, were the innocent and delightful objects of their Olympic games; and during those noble commemorations, war ceased, and all Greece assembled in happiness and joy. Even the harsh Spartans signed a truce of fifty days with the Messenians, that they might keep a fête in honour of Hyacinthus. The greatest men disdained not these contests. Plato appeared amongst the wrestlers at Corinth, and Pythagoras carried off the prize at Elis. What must have been the effect of all this upon a people of strong susceptibilities and of high natural genius?

Consider the respect which must have been paid to great artists, when such a man as Socrates pronounced them the only wise men. Æsop took the greatest pleasure in lounging in their painting-rooms; Marcus Aurelius took lessons in philosophy from an artist, and always said that the latter first taught him to distinguish the true from the false; and when Paulus Æmilius sent to the Athenians for one of their ablest philosophers to educate his children, they selected Metrodorus the painter, and, let it be remembered, that amongst the children placed under *his* care, was one of the Scipios. What must have been the effect on the rising youth of Greece when the Amphictyonic council decreed that Polygnotus, their greatest monumental painter, should be maintained at the public expense wherever he went, as a mark of the national admiration for his greatest work, the Hall at Delphi. The glory and the fortune of a great painter did not depend, as now, upon the caprice of individuals; he was the property of the nation; he was employed by countries and by cities; and his rewards were considered as a just portion of the national expenditure. The educated and the high-born were brought up with a conviction of the propriety and justice of this principle; and when they became members of the government, considered this as useful a method of public expenditure, as squandering thousands on matters merely diplomatic, or in vain shows, mummings, and pageants. And such will yet be the system of our own country, when the people become fully instructed, and are made sensible of the moral and commercial influence of painting.

When we reflect upon the money spent in England by the government, and the consequences which so often attend that expenditure, and when we find in Greece the different results of the same interference on the part of the state, and that the works there produced have been canons of beauty to the world ever since; it is natural to inquire, what was the system by means of which genius was so successfully rewarded? The secondary causes must have been, the competence of the tribunals to which poets, painters, musicians, sculptors, historians, wrestlers, boxers, and philosophers with such confidence appealed. It must have been the taste and

[1] See a beautiful passage *De Legibus*, lib. ii. p. 669.—If every scholar would mark and transcribe every passage relating to art, a code might soon be made out.

knowledge of the members which composed the judgment-boards, and their sincere conviction of the importance of their office. One has only to sift for a moment the nature of their greatest tribunal, that of the Olympian games; one has only to reflect on the deep feeling, the solemn sincerity, the awful piety of their conviction, that what they had to do involved the future prospects of the rising youth of Greece, and that on their moral honesty depended the glory of their country, and that of its painters, sculptors, architects, philosophers, poets, and heroes. Before proceeding to detail the rise and progress of Greek art, and Greek artists, as the painting of every nation is connected with its civil, religious, and scientific institutions (though more must always depend on highly-gifted individual effort to advance the knowledge of mankind, than any given assemblage of inferior individuals); a rapid examination of the principles which guided the decision of one of their most important tribunals, composed of the greatest men the world has seen, ought to form a portion of every history of the art.

Olympic tribunal.

Aristotle in his *Politics*,[1] as quoted by Mr Hamilton in his pamphlet on the Houses of Parliament, observes: "All were taught γραμματα or literature, gymnastics, and music, and many την γραφικην, or the *art of design*, as being abundantly useful for the purposes of life, but mainly because it enables us to appreciate the merits of distinguished artists, and carries us to the contemplation of *real beauty;* as letters, which are the elements of calculation, terminate in the contemplation of truth." A people thus educated, to understand the basis of beauty in art, and to believe that their decisions, when they became judges of genius, involved their own intellectual taste and repute, and who gave their decisions in the presence of kings, philosophers, and people, were as little likely to be biassed by unjust predilection as human nature could be; though, of course, in the corrupt times of Nero and the emperors, great abuses took place. But in the Marathonian period, if ever partiality was banished from human honours, it was banished from the Olympic games, in those immortal days of glory and patriotism. At this extraordinary assemblage, kings entered the lists, and nations respected the judgment, or if they refused to abide by the decision of a just tribunal, they were excluded by vote till they paid the fine and acknowledged their error. And what was the result? The highest honours were obtained in these contests, because every one gifted in art, poetry, music, or physical strength, knew that if he deserved the olive-crown, no partiality, no nephew of the judge's sister, or first cousin of the judge's wife, would deprive him of his due. Every being did his best, and if that *best* failed, he had a consoling conscious conviction that he had been honourably, and honestly, and nobly beaten by a better. It is astonishing, if once entire confidence exist between judge and competitor, to what a degree this confidence affects both; what a spring it gives to mind and body, and how honestly every thing is done: And if confidence be, from repeated experience, withheld, it is wonderful how half the faculties of the mind, and the powers of the body and soul, sink under the impression. Napoleon used to say, "that if the moral feeling of an army was in favour of a campaign, it was equal to 40,000 men." If moral confidence be lost in such cases, disgust is generated, and apathy, indifference, and failure are the result.

In order to understand the Greek character thoroughly, the system of excitement that was worked on, and the materials that were used to rouse the energies of competitors, it will conduce to the understanding of the secondary causes of their perfection, if the nature of the Olympic games be examined.[2] They are universally acknowledged to have subsisted before the rise of chronological dates and records; and the record of the Olympic conquerors after their restoration, is the first known chronological date. Pausanias says they were celebrated every five years, that is, they were celebrated on the fifth year after the fourth had passed; and Sir Isaac Newton is of opinion that they were originally instituted in celebration of victories. Why the Olympic games had always the preference, there is no knowing; but the grand statue of Jupiter at Elis, must no doubt have had considerable influence.

The privilege of presiding at the Olympic games was attended with such dignity and power, that the Eleans who had been in possession of it from the earliest times, were more than once obliged to maintain their right by force of arms. After various disputes about the number of presidents or hellenadicks, they remained at the original number of ten; and Pausanias says, that for ten months preceding the games, they dwelt together in a house appointed for them, and called from them, hellanodiceum. By the most scrupulous attention, they did every thing to qualify themselves for being deservedly the judges of *all Greece;* to which end they were patiently instructed by officers called guardians of the laws, and they attended every day in the gymnasium, upon the preparatory exercises of all those who were admitted as candidates, and who entered their names also ten months before, and exercised during a part, not the whole, of this time, in preparing themselves for the combat. Being exposed to the severest scrutiny, the judges had by these means frequent opportunities of trying the skill of the combatants, and also of exercising their own judgment; and both prepared themselves for the praise or censure of an awful tribunal, and a numerous assembly, whose censure could only be escaped by the most exact impartiality on the part of the judges, and the most sincere and earnest efforts for superiority on that of the competitors. In addition, the judges swore a solemn oath before the statue of Jupiter, upon their finishing the examination, to act according to the strictest equity and to all these precautions against human frailty, liberty of appeal to the senate at Elis was allowed to any one who felt aggrieved. The judges had also the power of excommunicating whole nations. Once an Athenian found guilty of corruption was fined, and refused to pay. The Athenians sanctioned his refusal, and were instantly excluded from all the games, till they repented and paid the penalty. When the Lacedæmonians were impertinent, other nations took up arms, and compelled them to submission. Such power had a wonderful effect on all the nations of Greece.

As the time approached, the candidates were rigorously examined as to their virtuous descent, and their own moral life; and when they passed in public review down the stadium, a herald demanded with a loud voice, "Is there any one who can accuse this man of any crime? is he a robber? is he a slave? is he wicked or in any way depraved?" Themistocles once stood up at the ceremony and objected to Hiero, king of Syracuse, because he was a *tyrant*, a name odious to the democracies of Greece; and there could not be a stronger evidence of their utter detestation of the name, than refusing to admit a king to contend because he was a tyrant; thus placing him upon a level with a slave, who could not by law be admitted. The candidates having passed in public review with honour, were then sworn, that they had done all which was required by law; and marching to the stadium, attended by their friends, connexions, and families, who encouraged them to do their best, and appealed to the gods to smile on their exertions, they were left for the fight. And being thus thought worthy of the contest, even defeat was considered by them as an evidence of their honour. The olive crowns and palm branches were placed before their eyes on beautiful tripods, to excite their utmost exertions, and when victorious it was announced by proclamation; they were crowned by the heralds, and then led along, preceded by trumpets, their names being shouted aloud throughout the vast assembly; and on

[1] Lib. viii. c. 31.

[2] See West's *Pindar*.

their return to their native city, they entered through a breach in the wall, drawn in a chariot. And such was the high feeling engendered by these judicious excitements, that even Alexander himself was refused permission to contend, because he was a barbarian, nor was he allowed until he had proved his ancient descent at Argolis.[1] "In the republic of the fine arts," says the catalogue to the designs for a National Gallery, "competition is the great source of excellence; but so to frame institutions, and invite competition as to secure all the attainable talent, and so to form a tribunal as to derive all benefit for the public, and to do justice to the competitor, have been matters of great difficulty in all ages and all countries."

The whole history of ancient art shews the estimation in which the unsophisticated judgment of the public was held. Aristotle[2] says, "The multitude is the surest judge of the productions of art;" "If you do not get the applause of the public," says some one else, "what celebrity can you attain?" and Cicero[3] makes the public the supreme judge. Thus then, no one ought to wonder at the perfection of Greek genius in every thing, stimulated as it was by these secondary causes, and the one acting upon the other, in a climate adapted in every way for comfort, for health, and for convenience. The Greeks were men like ourselves, not larger as their arms prove, and not handsomer, for there exist as fine forms in either sex, in Great Britain, as ever graced the atelier of Zeuxis; indeed Cicero complains of the plainness of the Athenians. When genius and secondary causes unite, as they sometimes do, then such men as Pericles and Alexander, and Polygnotus, Zeuxis, and Apelles, are the result; for all the Olympic games, and Greek tribunals, could never have made Hudson Apelles, nor Caligula the benevolent Howard. "If any thing were wanting," says Flaxman, "to convince us of the high estimation painting was held in by the Greeks, the facts alone, viz. that Plato studied it, and Socrat s was a sculptor by profession, are enough. But nothing is wanting."

In ancient painting, we certainly owe more to Pliny than to any other author; though in point of exquisite tact for hitting at once the characters of the great geniuses in art, he is not to be compared to Quintilian. There is more discrimination in the short account Quintilian gives of the painters and sculptors, than in all the delightful connoisseur chit-chat for which Pliny must ever be the leading favourite. Yet certainly his gossip and anecdotes are sometimes underrated by learned critics; for in two instances of gossip, about the partridges and grapes of Zeuxis and Protogenes, and the contest of Apelles and Protogenes very deep principles of Greek form and Greek imitation may be settled. Painting is said by Pliny to have existed before the foundation of Rome in Italy, as illustrated by designs on the walls at Ardea, Lanuvium, and Cœre. This is always mentioned with a sort of doubt by antiquarians, who suspect that to the arrival of Demaratus from Corinth, the father of Tarquin, king of Rome, Italy owes her first knowledge of painting; but it has been shewn that this cannot be so, if pictures were executed in Italy before Rome was founded. Pliny sneers at the Egyptians for boasting of the antiquity of their painting; whereas the Greeks equally deserve a sneer for believing that they had invented design.

Tabular and mural pictures; distemper and encaustic painting

The Greeks painted tabular pictures on wood, and mural pictures on walls. The materials were either encaustic or wax painting, and distemper or glue-painting. In encaustic on wood, they painted with a metal point called *stylus*; in distemper they painted with brushes, and in encaustic on walls they also used brushes. Tabular pictures were prepared with a ground of wax, and the composition was drawn in with a *stylus* or point as we draw upon an etching ground with a needle. At a sale of antiquities in London there was a regular Greek tablet with a wax ground, a stylus attached to it as boys hang slate-pencils to their slates, and a sentence of Greek actually half-cut. The word γραφω being used for painting, design, or writing, makes the instrument the same in either case. This tablet was like a slate; the middle had been planed smooth, and the frame was left round it. The progress of the Greeks is very interesting, and shews how the mind gradually advances to the imitation of reality, and rests impatiently on mere outline, as a representation of nature. After a certain time, the early artists, when they had drawn an outline, ventured to colour it inside with black. This mode of imitation was called σκιαγραφια, and the paintings σκιαγραμματα, or skiagrams, from σκια shade, and γραφω to draw. Our black profiles and whole figures seen in shop windows, are the skiagrams of the ancient Greeks. This was hailed as a great step, and the painter who could fill up a face or a figure with black was regarded as a man eminent in art. After a little came the genius with more extended views, who invented the μονογραμμα or monogram from μονος only, and γραφω, to draw; that is, to define *by line only*, an outline without a shade. Next came the man who had the nerve to try a *positive colour*. Pliny has preserved his name, Cleophantus of Corinth; he ground up a red brick,[4] and therefore the Greeks claimed the invention of colour, although the Chaldæans had painted men red on the walls of Babylon, and so had the Egyptians on their tombs, nearly a thousand years before them. This discovery was called μονοχρωμα, or monochrom, single-coloured from μονος alone and χρωμα colour, and this was their first attempt at imitating flesh.[5] Next came the white ground (the *gesso* of the Italians and lime and plaster of the Egyptians) covered with wax. From one colour, naturally enough came the others; for if brick produced red, earths, burned or natural, would produce other colours, and polychrom, from πολυς many, and χρωμα colour, was formed.

The art having now discovered its materials, soon advanced steadily and gloriously to excellence. "How long the brush assisted only the cestrum, and when it superseded it," says Fuseli,[6] "cannot be ascertained; it cannot be proved, that it ever entirely superseded it, and there is every reason to believe they were always combined." It has been contested that painting was not known in Homer's time, because he speaks not of art; but what would be said of any man who argued that painting was not known in Milton's time, because *he* did not speak of it. Homer speaks of *painting ships*, and Milton alludes to "the *painted stoa*;" but colouring and design must have been known from the shield of Achilles, and the tapestries of Helen and Andromache, if the walls of Thebes and those of Babylon had not settled the question. Troy was taken 1184 before Christ; but painting flourished in Egypt 1900 years before our era, that is, 716 years before Troy was taken, and 993 years before the era of Homer.

The nature of distemper and encaustic painting amongst the Greeks involves one or two questions interesting to artists. Their distemper was our tempera, and consisted in dissolving colour in water, and mixing it with glue; and though in Pliny, glue is only mentioned once, and that in conjunction with *(tectores)* plasterers, it is evidently to be inferred from the brushes used in its practice, that tempera intensely varnished was the general practice of the tabular painters, and encaustics the exception. On all encaustic pictures, the Greeks put (ἐνεκαυσεν) "burnt in;" and what justified them in doing so? Merely the general application of fire to melt wax, or a particular mode of practice. Was the cestrum or stylus heated, whilst finishing the work, after the wax had been laid on? or was any actual

6 Fuzeli, Lecture first.

heat applied to amalgamate the colour in the conclusion, which justified such a term? or was the wax actually melted and used whilst boiling? Pliny says, that there were certain colours which would not stand without varnish; and that after they were laid on walls and dry, they were varnished with a mixture of warm punic wax and oil. Every Greek artist had his chafing-dish or καυτηριον; and when the varnish was dry, it was heated by fire from the chafing-dish "usque ad sudorem," *until it sweated*, when it was rubbed with wax candles, and polished with white napkins. This method the Greeks called καυσις[1] or the burning mode; and why might it not be applied as well to encaustic pictures, when finished either on wood, copper, walls, or stone, thus harmonizing and judiciously amalgamating fierce execution or distinct touches, and authorising the word ἐνεκαυσεν being put after the artist's name?

All the artists in Europe know well how often they use a vehicle[2] for a varnish, and a varnish for a vehicle in practice; and hence it is too absurd to doubt for a moment, that any Greek painter who had once used oil and wax as a varnish, would not use it as a vehicle at the first opportunity. Pliny infers, that "ceris pingere," to paint with waxes (coloured) and "picturam inurere," to burn in the picture, were *the same methods*. "There were anciently," he adds, "two methods, one *cerâ*, with wax, and another on ivory with a cestrum; then came a third, boiling the wax and painting ships at once with it, which was a lasting mode, so that neither sea, wind, nor sun destroyed it." It appears from another passage, that the ships were painted in the same way[3] as pictures which were burnt in. "Waxes are tinted with these colours for pictures which are burnt in; a different manner of painting from that employed on walls, but like that (of waxes tinted) employed for painting ships." Were tinted waxes applied hot? From this it may be inferred that they were.

Encaustic painting may be divided into four methods: 1st, mixing the colours with wax, and thinning them at the moment of painting with a liquid; 2d, placing wax in colours on the ivory, distinctly like mosaic, and uniting them by working them over with a heated cestrum; 3d, boiling the wax and using it hot; and, 4thly, softening the whole picture after completion, by heating it with a chaffing-dish or cauterium. Both Pliny and Vitruvius describe this last method of varnishing; and it is curious to contrast their relative descriptions. Pliny is rapid, careless, general, desultory, as if talking at a party; Vitruvius, accurate, mathematical, careful, and architectural, as if every word was a brick, that must be poised and balanced. Pliny says you must liquefy punic wax with oil,[4] and rub it with a candle and napkins. Vitruvius says, after your wall is dry and smooth, liquefy punic wax, *paulo*, a little by fire, then *temper* it with oil. In Pliny the *paulo* is left out, and so is the fire; but Vitruvius guides you to the *degree*, which is every thing in the practice of the art of painting. The *paulo*, therefore, is invaluable; do not boil, but heat your wax, then liquefy it, then varnish, then when dry heat it with a chaffing-dish and rub it smooth. To artists this practice is beautiful, and though oil-painting was supposed to be unknown to the Greeks, this was very near the point, and if used by Polygnotus at Delphi or Thespiæ, would have justified the term *burnt in*, without the use of the cestrum.

It is not settled by Pliny who first discovered encaustic painting; it is not known, he says, whether Aristides may have invented it, or Praxiteles completed it. But there existed on the walls encaustic paintings by the old painters Polygnotus and Nicanor; Lysippus at Ægina put his name to his tabular works with ἐνεκαυσεν; Pamphilus the great master of Pausias, did not practice it exclusively; and Pausias was the first in this art. Pausias, Pliny adds, repaired the walls of Thespiæ, painted by Polygnotus, but being obliged to use the brush, failed, because he handled an instrument which he was not accustomed to. It appears, however, that the walls of Thespiæ were painted in encaustic by Polygnotus, and with the brush; or Pausias, the greatest encaustic painter, would not have been employed to repair them, nor would he have gone out of the way to use the brush, if Polygnotus had used the cestrum. But Pausias failed, because the brush was not his instrument; therefore encaustic on walls was not worked with the cestrum, as it was on tablets, and the burning in on tablets was not of the same nature as that on walls. That the brush and the cestrum were totally different in practice there is no doubt; but that there was ever a time when the brush was not used in painting is absurd; and Pliny is evidently wrong in saying it was the last method.

It stands to reason that to paint ships was the earliest necessity of navigation. The ark was pitched inside and outside (Gen. vii. 14). Pitch melted is in fact like wax or oil; and how was it to be equally spread over so vast a surface except by brushes? In fact, amongst the Egyptian antiquities imported of late years, brushes have been abundant. Thus the Greeks painted on walls, wood, stone, ivory, copper, and canvas; on walls it was *mural painting*, and on either of the other materials, *tabular painting*.[5]

There is another question which remains to be settled before touching on the great artists and their works: Did the Greeks paint in fresco? The belief has been that they did. Vasari affirms it; but Letronne certainly establishes the suspicion that they did not, except in a few ornamental parts of architecture, and that stucco was more in practice. In fresco the colours are placed on wet mortar, and become a part of it. In stucco the colours do not become a part, and can be separated. Certain colours are destroyed by contact with lime, and yet those colours which fresco would have ruined, *are always found on ancient painted walls*.

---

[1] It is clear that *fire* was always an important part in an encaustic painting, because Philiscus painted a painter's room (atelier) with a little boy *blowing the fire* (Pliny, xxxv.)

[2] Vehicle, as distinct from varnish, means the liquid you paint with; varnish, the liquid you put over the work, when done, to preserve it.

[3] "Ceræ tinguntur iisdem coloribus, ad eas picturas, quæ inuruntur; alieno parietibus genere, sed classibus familiari."

[4] That Reynolds introduced wax into British art from this passage, there is no doubt.

[5] Not many years ago a dispute raged in France and Germany whether tabular painting was or was not the principal practice of the ancients, and whether mural painting was ever practised to any great extent. Letronne says cloth was not used *anciently* to paint on, and that Pliny thinks the man mad who painted Nero on cloth one hundred and twenty feet high; but the madness insinuated does not apply to the *cloth or canvas*, but to the *absurdity* of a portrait one hundred and twenty feet high in cloth. Why should canvas be only *once* used in antiquity, and never before or after till the middle ages? Is this likely? As a curious specimen of the blind violence of party, the friends of one of the combatants, Letronne, wrote to him from Athens, that in the temple of Theseus they discovered by candle-light round the upper part of the wall, *actual contours* of the works of Polygnotus *cut in on the plaster with the cestrum*, the colours having been picked out by the early Christians; thus proving that Letronne was decidedly right as to his theory of painting on walls. Yet would it be believed, that the friends of his opponent, Raoul-Rochette, wrote him in turn that they *did not see a single contour cut in*, but that they discovered a *sinking in* of the plaster as if fitted to receive tabular works which were let into the walls, and thus the theory of Raoul-Rochette,—viz., that pictures were scarcely ever painted on walls, but nearly always on wood, *is right*, whilst the former gentlemen assert that there are contours on the walls. But the theory of M. Letronne *is also right*; for the ancients painted on walls as well as wood; and though Pliny says that the greatest glory was obtained by easel pictures, he affirms that there were also pictures on walls, because in giving one of his reasons for preferring tabular pictures, he says pictures on walls cannot be saved in case of fire (*ex incendiis rapi non possunt*), and that he prefers tabular pictures. If pictures had not been painted on walls as well as on wood, how could he have illustrated his preference?

Letronne says, that there does not exist a well authenticated evidence of fresco, except as mere ornament in ceilings.

Having thus laid before the reader the different modes of Greek practice, without which no subsequent account of their arts or artists would have been intelligible, it is time to say something of the artists themselves, who practised these various modes of imitating nature. Of their different methods, their white grounds descended to them from the eastern nations, and have come to us through the middle ages. Some of their colours we use now, and for some we have substitutes as good. If their principles were as easily attainable as their colours, we should have very little to desire.

Ancient Greek artists.

In the earliest state of Greek art, Philocles from Egypt, and Cleanthes from Corinth, were the inventors of outline, and Ardices from Corinth, and Telephanes from Sicyon, the first who put it in practice, without any colour. To this early period may be applied the accusation of Ælian,[1] that the artists were obliged to write underneath their wretched illustrations, "This is a bull, this is a horse, this is a tree." The next were single-colour painters, or monochromatists, as Hygiomon and others. Now the sexes began to be distinguished, when Cimon the Cleonean had energy to attempt the imitation of every thing. He it was who invented fore-shortening, and drawing things at an angle.[2] He it was who had courage to vary the characters and forms of heads, to make them looking up, looking down, and looking behind; he articulated his joints, shewed the veins and muscles, and gave undulation and folds to his draperies. Panænus, Phidias's brother, painted the shield of Minerva at Elis, and also the battle of Marathon; and so much had the knowledge of colour and art advanced, that portraits of the great leaders, Miltiades, Callimachus, and Cynegyras, on the part of the Greeks, and of Datis and Artaphernes, on that of the barbarians, were introduced, and known by the spectators. It was at this period that the glorious contests for victory in art were begun at Corinth and Delphi; and Panænus was conquered by Timagoras of Chalcis, who commemorated his victory by a poem; "though I doubt not," says Pliny, "there is some chronological error."

The Greek national and monumental painter Polygnotus, flourished at this period or before it. He seems to have been really a great man, and to have possessed a mighty soul. He was born in Thasos, an island in the Ægean Sea; and his works seem all to have been national, votive offerings of cities and his country. He was worthy of the finest period of Greece, and met his noble patrons by a suitable return; he was one of those beings who are born for the time or beyond it, and of whom the time is in want, or for whom it is not enough advanced. He first clothed lovely women in light and floating draperies, adorned their beautiful heads with rich turbans, and thus advanced the art immensely. In expression of face he ventured to make the mouth of beauty smile, and thus softened, by shewing the teeth, the ancient rigidity of his predecessors. He painted gratuitously the Hall at Delphi, and the Portico at Athens, called Ποικιλη, thus offering a contrast to Micon, who was paid. Such conduct was immediately judged worthy to be commemorated by the highest authority in Greece, the Amphictyonic Council, who ordered that Polygnotus should henceforth be maintained at the expense of Greece. Pliny has certainly not said enough of Polygnotus, whose great work at Delphi, described by Pausanias, proves him to have had colour in a high degree, imagination in the highest, and all which, according to Aristotle, forms the most important requisite in the language of painting. His work at Delphi was executed by order of the Cnidians, who had a treasure there, and had also built a stadium. Besides this building, they employed Polygnotus to adorn the great Hall, leaving him the choice of subjects; and as Neoptolemus, the son of Achilles, was murdered and had a tomb near the spot, these subjects related to the Trojan war.

It is supposed that because Pausanias describes one thing as above another, composition was little known, and that there were several subjects in one plane. But any one might describe the Cartoons at Hampton Court in the same way, and make a reader, who had never seen them, believe that one figure was above another, and several subjects too. Might not one say, "*Above* Pythagoras in Raffaelle's *School of Athens*, is Alcibiades listening to Socrates;" but because they are *above* one another, that is no proof that they do not *retire*. Aristotle settles his high rank better than Pliny or Quintilian. "Polygnotus," says he, "made men *better* than they are, Pauson worse than they are, and Dionysius the same as they are."[3] Polygnotus, therefore, expressed the leading points of the species man, and cleared the accidental from the superfluous. Cimabue did not do this, nor Massaccio, nor Giotto; but Raffaelle and Michel Angelo did; and when this is done, in painting or sculpture, the component parts of art must be equally advanced. Besides, when did Polygnotus flourish? Between the 84th and 90th Olympiad. The Parthenon must have been built; the beauties of Phidias's immortal hand must have been executed, such as we see them in the Theseus, Ilyssus, metopes and frieze of the Elgin marbles. And could any painter be a Goth in composition, when such knowledge of the art is visible in these perfect wonders? Polygnotus put the names to many of his figures; Annibale Caracci put "genus unde Latinum" to Venus and Anchises; Raffaelle gilded his glories; but what argument is that against the genius of either? The power of Polygnotus in painting the dæmon Eurynome, with a skin the colour of a blue-bottle fly, shews the truth of his imagination, as well as his power of observation and imitation. Polygnotus was a great genius, worthy of his age; and the "simplex color," applied by Quintilian to his works, only proves the purity of his taste in using it.[4]

Simplicity is not barbarism, any more than gorgeousness is true taste. About the 90th Olympiad the light began to dawn and to give promise of a glorious sunrise. Aglaophon, Cephissodonus, Phrylus, and Evenor, the father of Parrhasius, and preceptor of the greatest painters, appeared. These were all celebrated in their day; but one of the most important reformers was Apollodorus the Athenian, who flourished in the 93d Olympiad. He was the first, according to

---

[1] Ælian, lib. x. chap. xii.

[2] Catagrapha invenit, hoc est, obliquas imagines et varie formare voltus, respicientesque, suspicientes vel despicientes. Fuseli says *catagrapha* means *profiles*; but how could he *invent* profiles when *profiles* are the characteristics of the *earliest* art? At first all art is profile; but Cimon was a reformer. To draw downwards he invented oblique views, and varied the views of the head and face, looking behind, looking up, and looking down. Fuseli says *catagrapha* means profile; but profiles are not oblique representations but sections of the figure and face, in the same sense as architectural sections, that is, equal halves. The "obliquæ imagines," are *angular views*, seeing things at an angle; the passage is directly illustrated by the circumstances, that he made his heads looking behind, &c.; and how can a head looking behind be a *profile?* In some places it may mean so; in Pausanias, κατα in radical meaning is *downwards*, as if the eye looked at the top of the head to the feet, which is *fore-shortening*.

[3] Aristotle, *Poetics*.

[4] Hardouin's *Pliny*, lib. xii. c. 10, p. 893. Clari Pictores fuisse dicuntur Polygnotus, atque Aglaophon; quorum *simplex color* tam sui studiosus adhuc habet," etc. Now the *simplex color* of Polygnotus and Aglaophon was not *one colour*, like monochroms, but modesty in the arrangement of the *three* colours, red, yellow, and black, without blue. How then could the monochrom apply to Polygnotus, whose works at Thespiæ, Delphi, and the Poikile at Athens, were painted in all the variety these three colours could produce, and not confined to *one colour?*

Pliny, who expressed the *species;* and he was also the first who did honour to the glory of the pencil. But, after Phidias, Panœnus, Micon, and Polygnotus, one is inclined to question whether he was the first who expressed the species. Phidias, in the opinion of the ancients, was the greatest artist in sculpture. Plato says that Phidias was "skilled in beauty;" but to be skilful in beauty, argues the power of expressing the species, and a perfect knowledge of the construction; for beauty is the last operation, and is based upon the first. How then Apollodorus could have expressed the species better than Phidias or Polygnotus, it would perhaps have puzzled Pliny to explain. However, let us take what the gods have spared, and be grateful. "His, is the adoring priest," says Pliny, "and Ajax defying the lightning at Pergamus; nor was any tablet worth looking at before." That may be. The previous works were monumental, national, or mural, painted with brushes, and bold in execution. Tabular painting may have been a more delicate workmanship; but it is not to be compared with the true epic, any more than the highly-wrought easel pictures of Raffaelle, are to be compared with his frescos.

Ancient Greek painters.

"The doors," says Pliny, "that Apollodorus had opened, Zeuxis boldly marched through, about the 95th Olympiad; daring every thing the pencil could do, and carrying it to the greatest glory." Some place him in the 89th Olympiad; but this is a mistake. Demophilus or Naseas was his master. Apollodorus became envious of Zeuxis, because the latter improved upon the style he had introduced, and wrote a lampoon. Zeuxis became very rich, grew very haughty, and always appeared at the Olympic games in a purple robe, with his name in gold letters on the border. So high was his opinion of his own pictures, that, thinking no money could equal their value, he gave them away. From this feeling, he presented an Alcmena to the Agrigentines, and a Pan to Archelaus; he also painted a Penelope, in which her moral beauty of character was visible, and an athlete, so much to his own delight, that he wrote underneath, "It is easier to criticise than to execute." His great works were Jupiter and all the gods, and Hercules strangling the serpents. He was censured for large heads and violent markings, but otherwise he was strictly correct. Pliny varies his history with current stories, and we can almost get at the principles of Greek art from them as well as from the account of the art itself. Current stories and proverbs should never be disregarded; for, if not true, they may be taken as inventions characteristic of the parties, or they would never have been believed. The Agrigentines, says Pliny, ordered a picture for a temple of Juno Lucinia, and they allowed the painter to select the finest girls as models. Cicero[1] says it was the Crotoniates who employed him; and as Zeuxis always studied nature, the most beautiful girls were ordered by government to come to him, and having selected five, he then painted his Helen. Zeuxis made his sketches in black and white (*pinxit et monochromata ex albo*) or of a single colour heightened by white. His contemporaries and rivals were Timanthes, Androcydes, Eupompus, and Parrhasius. The contest of the last with Zeuxis, in which the one deceived the birds by grapes, and Parrhasius Zeuxis himself by his curtain, contains the great principle of Greek art, viz. *That the most perfect imitation of reality was not incompatible with the highest style.* Antiquaries are disposed to laugh at these stories as beneath the dignity of belief; but artists know well enough, that, so far from being unworthy of credit, all the stories of Pliny and Ælian tend more or less to illustrate a principle. Zeuxis painted a boy and grapes, and the birds flew at the fruit; but his rival observed that, if the boy had been equal to the grapes, the birds would have been frightened. Zeuxis was a great painter and discovered the principles of light and shadow.

After Zeuxis came Parrhasius, "liquidis ille coloribus,"[2] who was born at Ephesus, and celebrated for great excellence. He first gave correct proportions to painting; airs to the head, elegance to the hair, and beauty to the countenance. By the acknowledgment of all artists, the manner in which he *lost* the contours of his forms, was exquisite. Many people can execute the parts of which the middle of things is composed; but few can finish the boundaries of objects as if the substance was round, and did not end with the contour which defined it; thus giving one an idea as if something was concealed, and exciting the imagination to conceive what the eye did not see. This excellence Xenocrates, and Antigonus, who wrote on painting, conceded to Parrhasius; and not this excellence alone, but also many others. The best idea than can be given to the moderns of the works of Parrhasius, is by referring them to the pictures of Corregio, of which this is the great excellence. Parrhasius appears also to have had the same defect; for he softened the centres of his figures, and gave them too much pulpiness for the heroic. There remained, in Pliny's time, sketches of subjects, and of hands and feet, from which artists learned a great deal. He contrived in a picture to paint the people of Athens, and to give a true idea of their variable character; humble yet vain-glorious, timid yet ferocious;—and all these contrasts he expressed with great power. But Parrhasius disgraced his genius by yielding to what Johnson calls "the frigid villany of studied lewdness," and sacrificed his noble art to pander to the beastly appetites of the debauched; in fact, Tiberius kept one of his licentious pictures in his bed-room, namely, that of Meleager and Atalanta. But whatever may have been the habits of antiquity, and however indecencies may have been connected with religion, it is clear the greatest men did not approve of such prostitution of talent. Aristotle censures the practice, and warns tutors to guard their pupils from such corruptions.

Timanthes followed, the great painter of the sacrifice of Iphigenia in Aulis. No picture had more reputation for touching art and delicacy than this. After exhausting expression in all the principal agents, the artist covered the face of the father, not daring to trust his hand to attempt imitation, and leaving every spectator to imagine an agony of his own. As Euripides has the same incident, Fuseli thinks the honour of being the first inventor is due to Timanthes. In the death of Germanicus, Poussin hid the face of his wife. Timanthes seems to have been ingenious in his inventions; to give the idea of great size to a sleeping Cyclops, he introduced two satyrs trying to span his thumb. Pliny adds, that there was a head painted by him in the Temple of Peace at Rome, and which was a perfect specimen of art.

Euxenides taught Aristides, the great master of expression, and Eupompus taught Pamphilus, who was the master of Apelles, a name synonymous with perfection in finish, but not for invention like Zeuxis, monumental commemorations like Polygnotus, composition like Amphion, or expression like Aristides. No; Apelles was the deity of tabular pictures, the greatest glory of the art in Pliny's mind, but not in the minds of those who see beyond the range of a dining-parlour. Eupompus painted a victor with a palm branch in his hand; and such was his influence in Greece, that he was allowed to divide painting into three schools, viz. the Ionian, Sicyonian, and Athenian. Pamphilus was a Macedonian, who combined literature with painting and made it a principle of tuition, that no man could be great in either who was not a mathematician; for he denied that without geometry art could be perfected. He taught nobody under a talent, which both Apelles and Melanthus paid. So great was the influence of this distinguished man, that first at Sicyon, and afterwards in all Greece, he got it established as a principle of education, that all clever boys should be taught on tablets the art of delineating, which is the foundation of

[1] De Invent. lib. 2, chap. x.

[2] Horace.

painting. He considered this art as the first that should be taught in a liberal education. Slaves were prohibited the exercise of design; which was an absurd law, because in literature it would have prevented Æsop or Terence from developing their genius. What right have any creatures, who are obliged to eat and sleep like the meanest slave, to pass a law to prohibit the exercise of any natural talent, if the Almighty has not disdained to think one worthy of being so gifted? The consequence of this was, that no slave ever distinguished himself in the arts.

About the 107th Olympiad, after Echion and Theramichus, came the god of high finish and grace, Apelles. His style is always the precursor of decay. First came a race in art, amongst whom invention, expression, form, colour, and execution, in a series of pictures intended to illustrate a principle were enough, provided the principle was expressed. These were the *monumental geniuses*. But when the art becomes national and glorious, the noble and the opulent become ambitious to share the glory with their country; and the art sinks to the humble office of adorning apartments. As is the demand, such will be the supply; and the genius of a country is thus turned from national objects and public commemorations to private sympathies and domestic pleasures. At this period of Greek taste appeared Apelles; refined, accomplished, delicate, devoting his whole soul to single perfections equally adapted for a temple or a palace, and patronised equally by his sovereign and the people. Educated by Pamphilus, he was grounded to the very foundation, and consequently drew, as Burke says to Barry, with "the last degree of perfection." Apelles, Aristides, Nichomachus, and Protogenes, were the most distinguished artists of Alexander's time.

Apelles wrote copiously on his art, and explained its principles. His treatises were extant in Pliny's time, and even in that of Suidas,[1] who speaks of them; and as they were probably illustrated with designs, the loss is much to be deplored. Beauty was the leading feature of his style, as well as of that of the greatest painters of the same period. In grace he defied competition; and this explains the secret of his triumph. "I know when to leave off," said he, "which is a great art; Protogenes does not. Over-working is injurious." He was a very generous man, and acknowledged when others were superior to him; observing that Amphion[2] was a better composer, and Asclepiadorus more correct in proportion. Amongst all the stories of Pliny, the most delightful is that of Apelles and Protogenes, which seems to be an authentic fact; and even if it were not, it would illustrate the principles of Grecian art. Protogenes lived at Rhodes and Apelles sailed to see him. Having landed, he called, and found the artist "not at home." Being shewn by an old woman into his painting-room, he found a tablet with its wax ground ready for a picture, and taking up a brush, drew an exquisite line in colour down the tablet. Protogenes having returned, was shewn what had happened; and, contemplating the beauty of the form, he said it must be Apelles, as nobody else could draw so perfect a work. He then took the brush and drew another still more refined, saying, if the stranger call again, shew him this, and say that that is what he is seeking. Apelles returned, and blushing to see himself outdone, again took a brush and drew a third, leaving nothing to be exceeded in refinement, *(nullum relinquens amplius subtilitati locum.)* Protogenes when he saw this immediately sought his visitor, saying that he could carry the line no further. The tablet with these lines upon it, was considered by all the Greek artists as a miracle of drawing. After the death of Apelles and Protogenes, and the conquest of the Romans, it was preserved in the palace of the Cæsars on the Palatine hill, where it was seen by Pliny containing nothing but three fleeting lines *(tres lineas effugientes)* and yet superior to all that was to be found in the finest works. Unfortunately it was burned at the destruction of the palace.

Now comes the question, what were these lines which could thus speak to artists who had never seen each other, the common language of a common code of law for design. "*Secuit lineas*" does not mean actually to cut the lines in two, but in the technical idiom of English artists, to strike a line. It was not the metal cestrum, but the hair brush, and therefore *cut* in this sense could not have been meant. To *cut* with a brush means to design with an air of power. Three lines varied in shape would mean nothing, if nothing was expressed; but if some known contour of the body was taken in repose, three variations of its position without alteration would be as much as could be expected in the contour. Suppose that Apelles drew a line from the clavicle A to the pubis B of a body in profile, shaping all the parts as he went correctly like fig. 1. Next, suppose that Protogenes having come in saw the line, and knew that in finely-formed men, the stomach, from great exercise and temperate living, becomes small; the contour would curve in at C, so that that portion of the *rectus* muscle would retire, as in many of the Greek statues. He would then take the same contour, draw it again on the wax tablet, and make this variation. Again, suppose that Apelles returned and on seeing himself vanquished, took the brush and drew the same contour, allowing the variation of Protogenes, but remembering that in powerful men, the *pyramidalis* D, fig. 3, arising from the *pubis* and going into the *rectus*, makes another and the last variation. Then Protogenes returning, and seeing that nothing more could be done unless the body was altered in position, he would acknowledge the line to be completed.

Fig. 1.

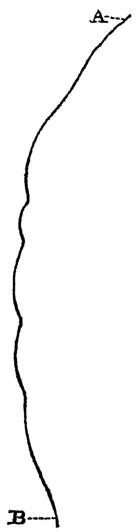

Fig. 2.

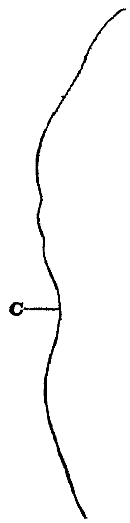

Fig 3

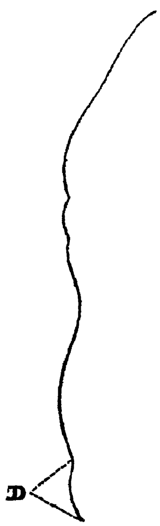

In Conduci's Five Dialogues, it is stated that Michel Angelo thought it must have been a contour of some part of the body. Now, this singular contest would be felt by all artists as one of the greatest utility. It would be wondered at by connoisseurs, and would illustrate a great principle; namely, that a knowledge of construction was the basis of correct design and the foundation of all beauty.

It was the continual practice of this eminent man to do something every day, whatever happened; and hence the proverb, "No day without a line." If artists were to write

[1] About the year 1100 of our era.

[2] Junius (*De Pictura Veterum*) only finds Amphion mentioned twice in ancient authors, and it is hence supposed that Echion would be a better reading.

Painting. this over their painting-room doors, it would not be without advantage. Rubens rose at four, and was in his painting till five in the afternoon, with occasional variations. All the greatest men of antiquity and of modern art, have been the most diligent and the most industrious. And here is the most celebrated of the tabular painters of antiquity afraid to let a day pass without the use of the pencil. Apelles used also to hide himself behind his works to hear the remarks of the public. This deference to the public voice evinced by sculptors, painters, and statesmen, is a beautiful proof of the sense and understanding of the time. Nothing was done in defiance of public taste, but every thing in conformity to its dictates; and though this does and often did lead to great injustice in political matters, in art the maxim is infallible.

Apelles of Cous excited envy enough, and notwithstanding his graceful manners, his tender heart, and his accomplished mind, when driven by stress of weather into Alexandria, the courtiers of Ptolemy, hating his superiority, and fearing his probable fortune, sent him a pretended invitation to sup with the king. Apelles went; the king felt astonished at the liberty, and sending to demand explanation, discovered the imposition. On inquiring if Apelles knew the person who had given him the invitation, he immediately sketched his face on the wall, and the king recognised the culprit. Courts, kings, and people can only judge of results. The infinite number of repeated acts, the *nulla dies sine linea*, the failures, the recoveries, the musings, the thinkings, that had taken place with the "cestrum cum lumine," they had not witnessed; therefore, knowing their utter incapacity to do as Apelles did, they concluded that he was a wonder, and he of course became a favourite. As an evidence of that peculiar tact by which such men are sure to please kings and nobility, namely, by the power of seizing the most agreeable expression of any sitter's face, however ugly, and rendering his very defects a cause of elegant concealment; he painted Antigonus, who had lost one eye, in profile, concealed his defective eye, and made him as graceful as if he were Alexander. This was the great secret of his fortunes, as it was that of Titian's, Vandyke's and Reynolds'; and though not to be compared in point of taste or knowledge of the art, this was also the secret of the popularity of Lawrence, mere portrait painter as he was, and nothing more.

Polygnotus, Pausias, Aristides, Timanthes, Zeuxis, Parrhasius, Pamphilus, Euphranor, and Timomachus did not so completely gratify the vanity of their contemporaries, and were not such personal favourites as Apelles; for there is no gratitude equal to the gratitude of being successfully painted. Kings bow to the unknown power of having their momentary expressions observed, seized, transferred, and fixed for ages, and whilst colours and canvas last, carried on, for the admiration of a distant age, when the existing one is past and forgotten. What can equal the gratitude of a woman to have her beauty preserved, whilst she is in her bloom, for the admiration of her children when age has shrivelled her form, or misfortune destroyed her happiness? The world may be elevated, excited, roused, by the commemoration of the great deeds of ancestors or heroes; but no sympathy is ever excited, and no personal vanities are ever so happily gratified by any class of painters, as by the great portrait-painter. The degree of imagination required is not of that irresistible kind which forces him to leave the model before him, using it only to realise his own burning conceptions, so that all likeness of the *individual* is lost; he requires no more than to retain in his mind the best expression of the individual before him to identify it upon canvas. But it must be exactly like, or it is nothing. After the likeness is completed, the sitter will have no objection to the highest degree of embellishment. There the great portrait-painter shews the degree of *fancy* wanted, and he that embellishes most, without losing resemblance, will be the most welcomed, as Apelles was, by the world. Painting.

To put Apelles in comparison with Polygnotus is out of the question. Highly-wrought individual figures, little more than portraits of beautiful nature, cannot rank so high in the judgment, though they may in the delicate sympathies of the world. But that single terrific conception of the demon Eurynome, for which no prototype in nature could be found, that momentary blush which crimsoned his Cassandra,[1] Aristotle's praise that he made men better than they were, and Plato's ranking him with Phidias, settles the question of his greatness; and as a portrait expression must be seen before it can be done, and must be like or it is nothing, there is an end of the highest quality of human genius, invention. Indeed, whatever the vanity of the world may be inclined to feel, the greatest portrait painter is but an inferior artist.

The age of Polygnotus and Phidias was the meridian age of Greek art; and that of Apelles was the setting glory. From the latter period it sunk gradually as if nature had been exhausted by the previous effort. Such ages have never since been seen; such perfection had never been realized before, and never will be again; for in order to become such sculptors and painters, men must also become idolaters. But to return and conclude the notice of Apelles, this court-favourite of antiquity. Notwithstanding the education of Alexander by Aristotle, notwithstanding that ἡ γραφικη was a portion of his education, Alexander was little more than a glorious barbarian in art. He talked so absurdly in the painting-room of Apelles, that the artist was obliged to request that his majesty would be cautious, lest the boys should laugh as they ground their colours. Apelles may be considered as the Titian of Greek art, with the addition of all that vast knowledge of form, which every painter and every school was obliged to master. But the disposition to perfect single figures, and the acknowledgment that others exceeded him in composition, clearly point out the extent of his fertility. Though Pliny describes many beautiful pictures, his greatest are single figures. His Venus Anadyomene was the most celebrated of all his works; but being painted upon wood, it was destroyed by insects in the time of Augustus. He began another, and having completed it as far as the bosom, died; but although the contours were completed for finishing, nobody would venture to touch it, such was the extreme veneration entertained for him. By this description we see the nature of the Greek process; first, the ground, then the drawing in, next the impasto preparation, and then the completion part by part. He had got the picture finished as far as the bosom; and therefore to finish highly by degrees was his system. He was not deficient in expression, for he painted persons dying with great power. His imitation must have been perfect, for his painted horses are said to have made real horses neigh; and his colour must have been exquisite, for he glazed like the Venetian school. Pliny mentions him as one of those who painted with four colours; but this is a mistake; for it was in the age of Polygnotus that *blue* was not used. From a passage in Cicero,[2] it appears that that age was famous for "form and contour;" whereas, according to the same writer, *all* things were perfect in the works of Protogenes, Nichomachus, Echion, and Apelles.

Pliny is therefore right in saying that pictures which constituted the opulence of towns, were painted with four colours only; but he is not as clear as usual in regard to the period to which this observation applies. Quintilian, calling the colour of Polygnotus "simplex color," seems to indicate the absence of *blue*; whilst *red*, *yellow*, *black*, and *white* did not produce such gorgeous splendour as in the age of Apelles. Thus Quintilian, as well as Cicero, collaterally proves Pliny to be in part right. It is extraordinary that Reynolds did not

[1] Lucian.

[2] *Brutus*, c. 18.

allude to the absence of blue in the enumeration of Pliny. Great depth, fine tone, simplicity, and modesty, can be obtained without blue, but never that tremendous magnificence produced by the contrast of the deep and awful azures of Titian. Though Polygnotus did not use blue, his black was made from vine-stalks and wine-lees,[1] which render black more blue than the ivory black of Apelles, which was discovered by him, and is used to this hour in Europe. There were several of the same name, but *Apelles Cous* distinguishes the great Apelles, as *Aristides Thebanus* does the great Aristides.

After this long account of the courtly, accomplished, and highly-wrought Apelles, there may be something interesting to allude to Aristides the "great master of expression," as Fuseli calls him. He was the first who painted deep human emotions, fierce passions, and distressing perturbations; but he was hard in colour, says Pliny, and not so harmonious as Apelles, probably like Raffaelle, the great Italian master of expression, in comparison with Titian. His finest picture was that of a mother dying from a wound which she had received in the sacking of her native city. Her infant was trying to reach the nipple with its boneless gums, whilst the mother, faint and exhausted, appeared struggling to save it from sucking, lest blood might mingle with its nourishment; a tender and affecting thought. Alexander was so touched by this picture at Thebes, when the city was taken, that he sent it to Pella.[2]

Protogenes was another of the great men of this time. It is indeed extraordinary to reflect how genius in art and literature seems always to come in clusters in every country. He was born at a small town on the coast of Asia Minor, subject to the Rhodians; and he got his living till he was fifty years old, in great poverty, painting beautiful ornaments for the prows of ships. He was not a man of fertile invention, and spent years over single works, which induced Apelles to say that he never knew when he had finished. His celebrated work was Talissus, which occupied him seven years. Titian took eight to paint the Pietro Martyre, and seven to finish the Last Supper for Charles V.;[3] and yet in Titian's works there is no appearance of over diligence. Pliny says he painted his pictures four times over, so that if one picture was destroyed another might be ready. Nothing shews so completely the exact degree of knowledge which Pliny had of art as this absurd conclusion from an admirable practice. Protogenes proceeded with his works as Titian did, by *stages;* and each stage was a separate impasto of colour, which helped the next till completed. Of this artist the story is told of his flinging his sponge at a dog's mouth in a rage, because he had vainly tried to hit breath coming out of it, and by that accident succeeding; a circumstance which shews that it was tempera painting, for a sponge would not have done for wax. Such a habit of daily application had Protogenes, that when Demetrius besieged Rhodes, he would not leave his painting-room, but proceeded daily in his studies amidst the noise of battering rams and catapultae. The king came often to visit him; and that part of the town where he worked was spared, and the picture thus finished was said to have *been done at the point of the sword.* Protogenes painted the mother of Aristotle; and the philosopher urged him to execute the battles of Alexander; but he was not a man of rapid conception or fertile invention for a series, and could not be moved.

It is curious to reflect, that all the great painters painted portraits; which proves that they thought it essential to that truth which was the foundation of their ideal beauty. Indeed, every great painter *should paint a portrait a month;* and if, like the Greeks, he has always nature for his works, he never can degenerate into manner.

Of the other painters, Asclepiodorus was celebrated for proportion; Nicomachus for rapidity of hand, and Theon for wild conceptions, "quas Græci vocant φαντασιας." Pliny places Theon amongst the herd, whilst Quintilian and Ælian place him amongst the illustrious, where he ought to be. He painted a single warrior dashing forward on the spectators; and collecting the public, he kept the picture behind a curtain, when in the midst of a blast of trumpets, the curtain was dropped, and the wonderful figure terrified the people. He also painted Orestes, distracted and insane, and proved himself a great and wild inventor. The three remaining great men of the fine period, were Pausias, Euphranor, and Timomachus. No passage has excited so much discussion as the well known one in Pliny, where he says, "nulla gloria artificum est, nisi qui *tabulas* pinxêre," as if he meant that the only glory in art consisted in tabular pictures, "πινακες," on wood, and that there was but little in monumental and mural efforts. Pliny, however, does not here contrast the tabular pictures of Apelles with the mural paintings of Polygnotus, but with the works of one Ludius, a Roman, a mere ornamental landscape-painter upon walls, like our Bond Street paper painters. This was much the fashion in Pliny's time, which he laments; and many examples of the same species may now be seen in Pompeii.

Having thus described the fancies and caprices by which the art had been degraded, Pliny turns to the highly beautiful tabular works of Apelles, and observes naturally enough; "This is not the thing; the glory of art and of artists consists in the Venus of Apelles, the mother of Aristides, the Ialysus of Protogenes, and not in this mechanical whim, which is not the glory and the end of painting." This, perhaps, is the explanation which he would give if he were alive and able to answer us. Is it not unjust then to take up such ground as M. Raoul-Rochette has done in France, and Payne Knight in England, and infer that there was no real glory in any other mode of painting? The ancients estimated mural painting at Delphi, as the Italians do in the Vatican. But they did not undervalue tabular painting, small pictures, encaustic, landscapes, or humour; they painted in every style and they excelled in all.

Pliny now proceeds to the encaustic painters, of whom Pausias and Euphranor appear to have been the greatest. Pausias was a master of foreshortening, as we learn from Pliny's description of a bull which he painted in front and projecting beyond the tablet. After Pausias came the Isthmian Euphranor, who wrote on symmetry and colour, painted great and small works, and delineated statues and animals. He said of his Theseus, that "it was real flesh, whilst that of Parrhasius had fed on roses." Then came Nicias who painted women beautifully, understood light and shadow, and was another pillar of art. Metrodorus was both a philosopher and a painter; and when the victorious Paulus desired Perseus to send him a philosopher to educate his children, and a painter to arrange his triumph, Metrodorus was despatched as a person capable of executing both tasks. Timomachus is the last of this splendid list whom it is necessary to mention. He died, like Apelles, leaving an important work unfinished.

Glory and decline of Greek art.

Such were the most illustrious men of the three finest periods of Greek painting. The first period of Greek art was that before Pericles; the second, or that of Pericles himself, was the finest, the highest, and the purest in painting, sculpture, and architecture; the third was the epoch

[1] See Pliny, lib. xxxv. The sea in the Venus Anadyomene is quoted as a proof that *blue* must have been used. But where is there any *blue* in Vandervelde? We do not think that a picture exists with *blue* in his sea.

[2] Raffaelle imitated this in his plague, where a fine youth is putting away an infant from a dying mother's bosom; but the utter want of taste in making the boy hold his nose for fear of infection, renders the sentiment not pathetic but at once disgusting and ridiculous.

[3] See, in Ridolphi, Titian's letter to the emperor.

of Alexander, the most refined, but prophetic of the corruption which followed; then came the subjugation of the Romans, when the noblest works of the Greeks were seized as tribute, or matters of right, and Italy was inundated by the productions of Greek talent.

Effects of the conquest of Greece.

This influx of foreign productions entirely suffocated native Italian genius. Greek productions became matters of property; and dealers sprung up who manufactured originals to supply the market of the rich collector. Galleries were formed to produce genius, which had sprung up from national demand without a single gallery or a single collection of any works, except the productions of their native soil. The most celebrated works were copied and re-copied by the Greeks in all parts of the Mediterranean. Horace alludes to this; and there can be no doubt whatever that the effect was to render all native attempts of the Romans and Etruscans no longer available. For not one great artist is named during the whole period of progressive decay from the Cæsars to Constantine; and the Romans or Latins never produced any talent worth consideration till the revival of art in Italy, after so many ages, in the fifteenth century. Then, the same principle operating, and the church and state demanding art as an assistant, outpoured an abundance of native talent, because there was a vent, as there had been before, in Greece, Egypt, and Chaldæa; and the genius of Rome, Florence, Pisa, and Venice, vindicated their long suppressed claims to originality. Amongst the illustrious Romans, Julius Cæsar seems to have been a magnificent collector; but whether, like Napoleon, he was also a magnificent patron of the talent of his time is not known. He bought Greek pictures, and presented them to Roman temples; but one work of native art, produced by native patronage, is more honour both to patron and to artist than a gallery of foreign pictures be they ever so divine.

Upon the whole, before tracing art from its decay to its revival, we cannot but acknowledge as evident, that a period of dearth in genius has generally succeeded in the world to one of prolific production. In painting and sculpture, secondary causes, such as the nature of the government, or the circumstances of the two arts being required for political purposes, may considerably facilitate the development of genius. But it is not so with the poet. He can give vent to his immortal thoughts in poverty or wretchedness, independently of the taste of the times, or the patronage of the state. Milton, in obscurity and blindness, wrote *Paradise Lost*; and Savage, in poverty and wretchedness, composed his *Bastard* in the streets, begging bits of paper as he walked, when he had more thoughts than his mind could contain, and thus, as effectually preserved them as if he had been bred in a palace, or had sheets of the finest *hot-pressed* to receive his lucubrations.[1]

Inferiority of the Roman school.

After the conquest of Greece, and the removal of art and artists to Rome, the genius of painting seems to have left the world. The Roman school of painting and sculpture is scarcely worth a single thought. In the last years of the republic the art sunk rapidly. Augustus tried to revive it; but though the pupils and descendants of the illustrious dead attempted to second his views, and though the writings of Apelles, Euphranor, and Pamphilus, were all in existence, and their principles known and acted upon, genius was nowhere to be found. That divine spark with its attendant whisper, unseen but not unheard, which ever attends the gifted who are born for great objects, whether it supported Columbus amidst the storms of the Atlantic, Alexander as he plunged into Asia, Napoleon as he rushed into Italy, Wellington at Waterloo, Michel Angelo when he painted the Sistine Chapel, Raffaelle when he entered the Vatican, or Phidias when he adorned the Parthenon; that supernatural, incomprehensible something, which inspires hope, "when the whole world seems adverse to desert," was gone from the earth like the glory which had blazed in the temple. All that the savage, splendid, imperial Romans could do, all the honours and riches they had to confer, were bestowed in vain. Architecture suited their savage vastness of mind better than painting; therefore architecture flourished, and Augustus was said "to have found Rome thatched, and left it marbled."

> Not Babylon
> Nor great Alcairo, such magnificence
> Equalled in all their glories, to enshrine
> Belus or Serapis[2] their gods, or seat
> Their kings, when Egypt with Assyria strove
> In wealth and luxury.

Claudius built a superb aqueduct, and Nero burned[3] and rebuilt a golden palace; but he could not replace the lines of Apelles and Protogenes, or the miracles of Timanthes and Aristides, which perished in the conflagration. Galba, Otho, and Vetellius were hurried through life and empire too rapidly for art; whilst Vespasian and Titus bewildered the Romans with their Cyclopean masses. Hadrian, himself an artist, endeavoured to recover art by indiscriminately encouraging Etruscans, Greeks, and Romans; "but such a medley of principle as their works displayed," says Agincourt,[4] "hastened the decay of art, and rendered the emperor hopeless of reviving it." The art thus went floundering on until Diocletian, with all the gorgeous splendour of an eastern monarch, mingled together Roman, Greek, and oriental art, and corrupting all taste led to its extinction. It was between the reign of Commodus and that of Constantine, that those causes were generated which undermined the empire, and brought art, science, and literature into the chasm. Of forty emperors who, from the second to the fourth century had struggled for the diadem and obtained it, twenty had been murdered by the army and the people. "Ainsi" says Montesquieu "comme la grandeur de la république, fut fatale au gouvernement républicain, la grandeur de l'empire le fut à la vie des empéreurs."[5] Constantine's removal of the seat of empire did not so much begin the destruction of art as complete it; for previous causes, domestic and political, had been preparing the ruin for centuries before.

Age of Constantine.

Agincourt thinks that as far as art is concerned, too much has been attributed to this removal of the empire. But yet the first epoch of what may be called *modern art* in opposition to *ancient*, must date from the introduction of Christianity as a state religion, when the whole moral feelings of Greek and Romans took another turn in painting and sculpture. Although Constantine only grafted Christianity on Paganism, and founded more catholicism than Christianity, by meeting and uniting the prejudices of both Pagans and Christians; yet surely if genius could ever be created by patronage, the age of Constantine, and those of Charlemagne, and Louis XIV. ought to have rivalled those of Pericles and Julius. Such was the rage for splendour in this reign, that the quarries of Phrygian marble and of the isle of Proconnesus, were almost destroyed to furnish palaces for the emperor, his sons, and his ministers. Temples, palaces, forums, triumphal arches, colossal statues, an hippodrome, and eight public baths were built and adorned at once; and in addition, splendid commissions were given to the painters for pictures of Christ, the Virgin, the prophets, and the apostles. Rome, Naples, Capua, Antioch, Tyre, Jerusalem, and even Bethlehem, felt the effects of this mag-

[1] See Johnson's *Lives of the Poets*, art. Savage.

[2] In this beautiful passage, the immortal author has made the penult syllable of *Serapis* short, whereas it is in reality long, *Serāpis*, an error which could scarcely have been expected in one who was a great scholar as well as a great poet.

[3] Tacitus does not seem altogether to believe it. [4] Agincourt, *Histoire de l'Art*, tom. i. [5] *Décadence des Romains.*

Painting.

nificent employment; but what were the results to painting? Nothing, absolutely nothing, to guide anybody except the antiquary; and if any evidence were wanting to show that the genius and the patron must exist together, or the result will be nothing, the end of Constantine's splendour would abundantly supply it.

The moral character of ancient Greece was gone; the instinct of public glory was passed; their olive crowns, the adequate reward of talent on a great principle, were sneered at; and "Lucian," (as the author of the *Discours Historique* observes) "had already ridiculed this tribunal," which had listened with rapture to Herodotus, and crowned Aëtion for a fine picture, and which in its days of Marathonian glory, had done more than ever was done before or since in rousing human effort, mental and bodily, to its highest pitch of excellence. Luxury, indolence, vice, fanaticism, cant, sophistry, intrigue, and imposture, had supplanted the pure aspirations of patriotism and glory. "The great and the opulent," says Pliny and Vitruvius, "were fonder of gold and glitter than purity of design or pathos of expression, or perfection of form; overwhelmed with colours from all the countries of the earth, with double the advantages of Polygnotus, and Zeuxis, and Aristides," who painted with four only, "nulla nobilis pictura est." Of course, this is always the end, when the moral and national importance of painting is undervalued. When native art is despised, and spurious foreign productions are preferred; when connoisseurs of what *is past* abound, and connoisseurs of what *is passing* exist not; when painting is considered as a bauble or a bit of furniture, and painters share dignity with upholsterers and gilders, what wonder if "*nulla pictura*" is the cry?

Gold and vermilion being thus introduced upon the walls of palaces and preferred to beautiful art, in came arabesques. Claudius had before introduced Indian patterns and mosaic pictures, which had hitherto been kept for pavements, till Commodus, for the sake of a new sensation, had a portrait in his palace of Piscennius Niger,[1] painted in mosaic, which may be considered as the first picture of this description. When painting was in this staggering condition, Justinian gave it a final blow by ordering encaustic and distemper designs, as vulgar, to be banished from ceilings and walls, and mosaic, marble, and gold, to be preferred. Though mosaic was perhaps one of the means of preserving art and of introducing it into Italy, yet it should only be used in pavements, or to preserve the works of great masters. The anti-pagan zeal of the early Christians is well known. They used to put ropes round the necks of Apollos and Venuses to try them publicly, like criminals, find them guilty, and pound them to dust. But human nature is always the same. A thousand years afterwards a similar scene was acted in Scotland by John Knox and the reformers, nor had England escaped the fury of iconoclasm. Eusebius[2] informs us that in the empire whole towns rose and destroyed the temples in which they had just worshipped. The air echoed with the noise of hammers, the crashing of pediments, the breaking of pillars, and the shouts of a maddened and frenzied populace. The finest works of Phidias, Scopas, Polycletus, and Praxiteles, and all that was left of Polygnotus, Apelles, Zeuxis, or Euphranor, were demolished or burned, like wretches who had infected religion, and their ashes were danced on with fanatical exultation. So great indeed had been the destruction, that when Arcadius and Honorius issued a fresh edict to go on destroying, they added, as well they might, "Si qua etiam nunc in templis fanisque consistent, "If any pictures or statues are still left." During this frenzy was introduced into art, *painting without nature*, and after producing a race of monsters down to Golzius and Spranger, there began the cant of "nature putting an artist out." What Zeuxis did not dare to do, what Apelles never thought of, what Phidias never permitted to be mentioned in his school, a parcel of painters brought into practice by the very mysticism of their impossible theories. Man was corrupt, being born in sin and vicious in practice; to take him as a model therefore when painting holy subjects, was to act under the influence of Satan. Man was banished, and so was woman, and nature in every thing; till at last all painters painted in one way, and in came *manner* into the great art of nature, and like a "leperous distillment" stained her garment and poisoned her beauty. Yet the traditional maxims of the ancient fathers, on beauty and art, give one a very good idea of what were the maxims of the finer Pagan periods. "Art is nothing but an imitation of nature," says St. Athanasius, (*Orat. contr. Gent.* c. xviii. p. 18.) "Ancient artists sought to surpass each other by faithful imitation," (Arnob. *Advers. Gent.* lib. vi. fol. 68) "Nature is the archetype, art the image; every image has a model, and painters imitate what they see," (Theodoret.) "Imitation is the merit of painting; be not seduced by an illusion," (St. Clement.) "When begging the people not to be seduced by pictures and statues as if they were gods, tell them that pictures and statues are imitations of nature, and therefore cannot be gods." These maxims of the fourth century had clearly descended from a nobler era. Besides the treatises of Apelles, Euphranor, and Pamphilus, were all in existence, and were read by the educated and accomplished; and we see how skilfully the fathers of the church tried to save fine works from destruction, by assuring the people that they were *mere imitations of life*, for such was the principle of artists. Are not these quotations then collateral evidences of the practice of the Greeks, if we had known nothing of the girls of Crotona sitting to Zeuxis?

Influence of Christianity on the arts.

But Christianity was at first the ruin of art, by making purity of heart every thing, and physical ugliness, or deformity, nothing; by teaching that as all beautiful works of art were remnants of idolatry, they ought to be destroyed; and by inculcating that mankind being corrupt and born in sin, no Christian painter ought to look at the naked figure whilst he was painting it. Add to these prejudices, the predilection of eastern nations for gold and silver, the preference of eastern dresses to the simplicity of Greek clothing, the controversies which took place as to whether our Saviour was ugly or handsome, and the vehemence with which Pagans and Christians both entered into them; and no one can wonder at the state into which painting declined.

Representations of Christ.

The division of opinion about the person of Christ, and the dread of the early Fathers to expose the cross to Pagans, who, familiar with golden-locked Apollos and perfumed Venuses, could not comprehend that suffering and majestic pains were founded upon a higher philosophy, so embarrassed the painters, that to avoid collision they painted Christ *as an allegory* thus lingering with their Greek feelings about the form of beauty and of grace. It must be interesting to all readers thus to trace the progress of feeling relating to the head of Christ.[3] In the fourth, fifth, and sixth centuries, beauty and youth still predominated; and he is painted youthful and handsome, crushing the lion under his feet, or as a young shepherd with his flock. With allegory the beauty of our Saviour ended, whilst the Fathers of the church, like the priests of Egypt, interfered, and issued an edict ordering him to be represented in agony on the cross. But here the order was evaded. The Greeks still struggled for the beautiful, and as if it were the never-dying principle of their souls, painted our blessed Saviour dying upon the cross, but smiling with triumphant glory as if re-

3 St. Augustin declares that in his time no faces of Christ or the Virgin were known, and that no pictures were painted of them before the council of Ephesus; yet there are seven reported originals, four of which are by St. Luke's own hand, now in Rome.

Painting.

joicing in his sacrifice. In whatever the Greeks were compelled to do, beauty seemed still to be the basis of their art. By degrees, however, the poor descendants of Apelles and Polygnotus finding no employment except on the conditions prescribed, the person of Christ became gradually degraded in art; and at the separation of the Latin church, to paint him ugly, bloody and agonized, was the settled principle of representation, and has more or less influenced his representation ever since. There seems to be some doubt as to the extent of the devastation committed by the Goths. Alaric stayed but three days in Rome, and Attila had himself painted in one of his Milan palaces seated on a throne, and receiving the homage of a Roman emperor.[1] Theodoric seems to have had a very good feeling for art. He laments, in a letter to Symmachus, the ruins of works of genius, begs their preservation, and concludes with observing that Rome has still a *population* of statues with herds of bronze horses. The expulsion of the Goths and the invasion of the Lombards, again afflicted the art; but it had found its way into France, and the churches of Paris, Tours, Bordeaux and Clermont, were ornamented by native painters.

Epoch of Charlemagne.

Though the popes had begun to adorn the churches, and art in the earliest times had been kept alive with considerable talent in the catacombs in Rome; though Europe had been astonished by the splendour of the ecclesiastical patronage of painters; yet the next great epoch after Constantine originates in the efforts of the illustrious Charlemagne. He formed the plan of renovating art, science and literature; and he would have accomplished his object, if the genius of the age had been worthy of the emperor. The ancient practice of painting churches, kept alive by previous popes, he confirmed by a law; and agents every year visited the provinces to see that the law was observed. If a royal church was to be painted, the bishops and abbots were responsible. If, in the midst of a campaign, an order was issued for a church, one to paint the walls was included; and no church was considered as finished till that was done, the object of the emperor being to obliterate the remembrance of the splendid altars of the Pagans, by still more magnificent Christian ornaments. "Repair your church," says the archbishop of Treves; "you know the decision of the emperor."

Two monkish painters of the time are celebrated; and France and Britain began even at this early period, to take an interest in the arts. Biscop, abbot of Weremouth, had brought pictures from Italy. Charlemagne had invited king Offra to protect painting, with but little effect; yet though the walls of English churches were whitewashed, the English began to adorn the ceilings and the windows, and hung tapestry upon the walls.[2]

In Spain, the Arabians had introduced their art, such as it could be, under the prohibition of Mohammed; and miniatures or manuscripts were so eagerly bought all over Europe, that the artists in France, Germany and Italy, devoted themselves to this production; though here again it was acknowledged by all, that they were beaten by the Greeks. In spite of all this, the art continued to decay; and at the second Council of Nice the members gave evidence of the state to which monks and bishops had reduced it. "How can painters be blamed?" say they; "the painter *invents nothing*. Invention and composition belong to the Fathers;[3] the art alone is the painters'." Inadvertently, too, the emperor injured the art by altering the dress of his cavalry and foot. The women as usual followed the example, and having relinquished the pure taste of the Greeks, dress has in consequence become an annual novelty and change. The Paladin and his horse were covered with iron and mail; angles and straight lines predominated; the naked form was more than ever concealed, and the artist deprived of his materials.

The middle ages.

Though the art suffered at the death of Charlemagne, yet it was kept alive by monks and by bishops. At Rome, at Palermo, and at Milan, religious painters preserved it from decay; they sprung up all over Europe, and even St. Dunstan, Archbishop of Canterbury, is spoken of as a skilful painter and maker of instruments.

It is curious, after all that has been written about oil painting, and the discovery made by John Van Eyk, to find a writer of this period called Eraclius, in a treatise on painting, speaking of oil painting: "De omnibus coloribus cum oleo distemperatis." Another monk wrote a treatise, in which he says, "he will tell the world how the Greeks mixed their colours." Now, as according to Suidas, the writings of Apelles and Euphranor, were in existence in the tenth century, and these people lived about that time, there is reason to believe that they were aware of oil painting having been practised in ancient Greece, and that subsequent discoveries were but different revivals.

Whilst the art feebly struggled on in the west, the court of Constantine Porphyrogenitus was the rendezvous of artists, and in 997 St. Mark was built at Venice by Greeks. In contrasting Greek with Roman art at this time, the Greek is still superior. The Greek composition did not want dignity, whilst in the Roman, all sound principle seemed dead. The most ignorant Greeks shewed taste in their draperies, and their heads have character, and in the arrangement of hair, they remind one of the Panathenaic procession; whilst the Romans, with their large heads and long limbs, evince a gross ignorance of beauty.

In the tenth century, tapestry for a time superseded painting; though in Germany, France, Italy and England, many painters flourished. In England, historical commemorations were in fashion, and the Duchess of Northumberland adorned Ely Cathedral with a series of pictures illustrating the deeds of her distinguished lord.[4] When William the Conqueror came, he introduced a new style of architecture; but both at York and Canterbury, paintings then adorned the walls. In 1013, a head of Christ was executed in mosaic, and is still considered as the wonder of the middle ages.

Symptoms of revival.

After so many vicissitudes of fortune, painting now began to shew symptoms of revival. Frescos had been executed in Rome in 498, and in 795; and there was a head of Christ painted in St. John Lateran, and still to be there seen, which gave evidence of great feeling. But the grand impulse was given in the year 1066, when St. Didier sent for Greek artists to adorn Monte Casino at Subiaco. The example was followed. Pisa, Venice, Amalfi, Genoa, and Milan, all municipal corporations rivalled each other; and when Pisa sent to Greece to collect as many splendid remains of art as could be obtained to adorn the dome of the city, Buschetto, a celebrated Greek architect, was engaged to superintend their embarkation, to accompany them during the voyage, and to land them safely for the purchasers. Buschetto was received with so much enthusiasm, that he founded a school of sculpture, which existed for two hundred years; and ultimately out of this very Greek school, came the great artist Nicolo Pisano, the head of the Italico-Pisan school. From this moment art, after having sunk to the lowest barbarism, went on improving till the taking of Constantinople by Mohammed II., an event which scattered the Greeks collected at that court all over Europe. Hundreds went to Italy as painters, sculptors, chasers, and mosaic painters; and by their struggles for existence, inoculated Italian artists with some remnant of their taste for beauty, decayed as it was. Cimabue was their pupil, and Giotto was his. The Catholic church wanted artists, and genius again began to shew itself. One man of genius appeared after another, till Michel Angelo,

Painting. Leonardo, Raffaelle, Titian, and Corregio, were the glorious results. And though it cannot be denied that the high aspirations of Christianity, by placing every thing human on its proper level on earth, in comparison with eternal happiness, had justly prostrated the splendid beauty of Pagan art, by exposing its idolatrous tendencies; though the sufferings, and the agonies of its founder and its martyrs had revived its pathos with higher objects than mere beauty of form or face, and saved painting and sculpture from extinction; yet it must be acknowledged, that the beauty of Christian art has never rivalled the indisputable perfection of the Pagans. To their enthusiastic overestimate of the religious value of physical, as emblematic of moral beauty, is their perfection attributable; but if it can only be revived by some similar delusion, the result will in our opinion more than atone for any thing that seems doubtful or questionable in the principle.

The most eminent pictures of the middle ages, setting aside the cemeteries or catacombs, which cannot legitimately be referred to the middle ages, but to the earliest ages of Christianity, are to be found in Rome. The greatest works of the middle ages are the series of Popes, begun in the fifth century, and continued down to the present time. The next, which was executed in the year 1011, is the painting of the church of St. Urbano, where some of the acts of the Apostles are represented on the walls. Though the mosaics of St. Mark's, executed by Greeks, were earlier, and kept art alive, yet, according to Lanzi, nothing in reality appeared which gave symptoms of the approach of any thing extraordinary, till about the thirteenth century; and this revolution of style was entirely owing to sculpture.

Italian schools of painting—The Tuscan. Pisano.

The glory of this art belongs partly to the Tuscans, the legitimate descendants of the ancient Etruscans, but most especially to the Pisans, who first had the courage to burst the yoke which Greek art in its fallen state had imposed upon them, and to go at once to the antique; and this glory belongs to Nicolo Pisano, a pupil of the school originally founded by the Greek Buschetto. There were in Pisa several ancient sarcophagi, but especially one, containing the body of Beatrice, mother of the Countess Matilda, with a bas-relief in good style, which served as the model of Nicolo; on this he formed his style, in which there is something of the antique, especially in his heads and draperies. Many artists who had not done so before, immediately devoted themselves to sculpture; and Nicolo Pisano must be considered as the first Italian, who opened the eyes of his contemporaries to the true principle of using the antique, that is, keeping nature in view at the moment of practice. In 1231 he cut an urn in Bologna, whence he was called "Nicolo of the urn;" and he produced two stories of the last judgment at Orvieto, and another work at Pisa, which convinced the world that he was born to found an epoch. He executed other great works, and was really the head of the illustrious school which produced Orcagna, Donatello, and the famous Lorenzo Ghiberti, who made the beautiful bronze doors of which Michel Angelo said, that they were worthy to be the gates of paradise.

Many other eminent men came from his school. All Italy was more or less affected by Pisano's genius; and though a sculptor, his effect on design was so great, that he must be considered as having had a material influence on painting. Painting remained behind sculpture, and even mosaic; and Vasari exaggerates the effect of Cimabue's appearance in the year 1240; for Lanzi proves that there were Pisan painters of talent before that period, and that the early art does not in the first instance owe so much to the Florentines as Vasari has asserted. At Assisi there is a crucifixion by Guinta Pisano, who, according to an inscription, learned his art from the Greeks in 1210. This was before Cimabue; but Lanzi says that the work is not inferior to Cimabue, and in drapery, colour, light, and shadow, composition and expression, very like the contemporary Greeks. Guinta disappeared and died, nobody knows where or how. Guido di Sienna was another name of this early period. In the Louvre there were some exquisite heads of angels with gilt glories, full of beauty and expression, executed by this artist. Then followed Margaritone, who painted on canvas, covered with size and plaster for a ground; which the Egyptians, Greeks, and Romans, had done long before his time.

During the time that the neighbouring cities had founded a new style, Florence had no painters; but when the authorities called in some Greeks in 1250, it is asserted that there was a painter called Bartolomeo. Vasari wishes of course to infer that Cimabue was the first Italian painter who gave the impulse; but Lanzi proves the contrary. Although there is no city we owe so much to as Florence, yet the Florentines ought not to be allowed to deprive their old enemies of the honour of having produced earlier painters, besides Pisano.

Cimabue.

Cimabue, who was both architect and painter, was honourably descended. That he might have been the scholar of Guinta is probable, because the Italians knew more than the Greeks of that time; but there is every reason to believe that he learnt of those Greeks who had been called to Florence, and whom, according to Vasari, he stood whole days, when a boy, watching as they painted in Santa Maria Novella. From this moment indeed may be dated the excitement which impelled him to become a painter. At Assisi his genius seems to have been put forth with most power. Lanzi concludes the notice of him by saying, that Cimabue was the Michel Angelo, and Giotto the Raffaelle of his age. In the Louvre there were one or two large examples of Virgins, staring and Gothic, and which the French, still more Gothic, were absolutely repainting.[1] Vigorous in his colour, and colossal but ill-proportioned in his figures, Cimabue first gave indications of attempting something new in painting; indeed, his watching the Greeks all day is so like an infatuated youth, that it bears truth on the face of it. Florence was often in commotion when his works appeared; and although he was not actually the oldest painter, he was the first of that series which ended in Raffaelle. His style was meagre, his drapery sharp, and his colour a species of illumination; but though he had no light and shadow or perspective, he was a great man for his time; and in some of his heads there are both character and expression.

Giotto.

Men of genius assist to call forth men of genius. In the neighbourhood of Florence, Cimabue accidentally found a youth tending sheep, and trying to draw one upon a slate. After some conversation with the boy, finding the youth ambitious to become an artist, he consulted his father, took him immediately under his own tuition, and advanced him rapidly. Cimabue was amply repaid for his generous conduct, as the innocent youth was Giotto, afterwards one of the great men of the time. No man can judge of Giotto's genius in England, because fragments of single heads or bits of altar pieces, are no fair criteria of a genius like his. His series of pictures in the Campo Santo are admirable, if allowance be made for the taste and simplicity of the age; but there are many actions and positions of Giotto, as fine as can be conceived, and which other artists by aggrandising in form, have rendered models of imitation. He was the friend of Dante, and painted the portrait of the great poet. He seems to have been a facetious and amiable man as well as a genius, and was indisputably the greatest painter till Massaccio. He

[1] The writer of this article, who saw a Frenchman solidly repainting a large picture of Cimabue in the private rooms of the Louvre, where he was admitted by Denon, asked the Frenchman who it was by: "Monsieur," said he, "je ne suis pas peintre, je suis restaurateur."

Painting.

went about Italy scattering seeds every where, and when the Papal See was moved to Avignon, he went with the court. Giotto was the greatest of the Florentine school. He was the father of painting, as Boccaccio was the father of literature. He was sought for at Ravenna, and at all the great towns of Italy, and was patronised by all the first families. He was an object of study and admiration, until the time of Raffaelle, and that of the Caracci, and is so even at the present time. There are in Giotto instances of pathos and expression, which would do honour to any period. Thus the greater part of the merit belongs to the Florentines, but not the whole. Giotto died in 1336, when painters had increased immensely. In 1290, the first society of artists in Venice was established, under the protection of St. Luke. They were not academies, but associations of artists, composed of engravers, painters, sculptors, and orefici. Their object was to advance design in all arts; and had they always continued to act on this honest and simple principle, we should not now have had to lament in Europe a race who are synonymous with every thing weak, mannered, and absurd in art.

Buffalmaco

The next distinguished artist was Buffalmaco. Although totally independent of Giotto, he was also intimate with Boccaccio. He was very capricious, and worked only when he liked, yet he was inferior to no one. He painted the Crucifixion, Resurrection, Ascension, and Creation of the World in the Campo Santo; in fact, the Campo Santo seems to have been a receptacle for all the distinguished geniuses as they appeared in that age. In it there are things as fine in conception as were ever imagined; and the foundation of some of Raffaelle's best compositions in the Vatican may be there found. Vasari's life of Buffalmaco is exceedingly entertaining, as indeed all his lives are.

The Orcagnas.

The two Orcagnas, Andrea and Bernardo, were the next artists of this early school. Andrea painted the Judgment and the Inferno, in the Campo Santo. He was full of invention, but not equal to the Giotto school, though he first gave evidence of perspective. Lanzi thinks that the art did not advance so quickly after Giotto's death as it ought to have done. Taddeo Gaddi, his best pupil, was to him what Julio Romano was to Raffaelle. Vasari, who saw his pictures in good condition, says, that he excelled his master in fleshiness and colour. Agnolo Gaddi the son of Taddeo, was a humble imitator of Giotto and his father, and had as his pupil Cennino Cennini, whose treatise on the mechanical preparations of the art is very valuable. Fortunate would it have been had the treatises of Apelles and Euphranor also reached us.

Florentine school.

Pisa now began to decline, and the Florentines took possession of that city in 1406. Hated and detested by their conquerors, the spirit of the citizens sunk into the greatest depression; the artists left the city, and the school entirely decayed. The Florentines now rose in the ascendant. The Medici began to appear. Cosmo, the father of his country and the protector of genius, gave fresh energy to art, science, and public affairs. Lorenzo followed, and their house became the refuge and resort of all who were celebrated in painting, poetry, sculpture, architecture, and philosophy. Massaccio, the two Piselli, the two Lippi, Binozzo, Sandro, and Ghirlandaio, received from the Medici protection and employment. The pictures of the time have perpetual portraits of the Medici. The citizens became animated with the same spirit; frescoes covered the churches, and smaller works filled the houses. Up sprung, too, that host of painters, marble-cutters, bronze-casters, and chasers, by which the principles of design passed from Pisa to Florence; and out blazed before the world Donatello, Brunelleschi, Ghiberti. The most exquisite productions of sculpture, marble, and bronze followed. The youth became inoculated; sound design became the first necessity of manufacture; and though the finest works of Italy at this or any period cannot be compared to the finest works of Greece, yet a good style of design was established, but unequal to those refined forms of beauty, so palpable in the merest fragments of the works of the school of Phidias, which have all the look of life without any of its vulgarities, all the essential details, without a single superfluous one. This cannot be said of the naked figures of the period in question, or of any period of Italian art, not even of the art of Michel Angelo and Raffaelle. There was a want which Greek forms only supplied; there was an absence of refinement, and a want of something which the Greeks possessed. Michel Angelo and Raffaelle were educated without system. There was no school in Italy like the schools of Sicyon and Rhodes, Athens, and Corinth, where all the hidden secrets of perfect form were taught, that is, the secret of beauty. Michel Angelo and Raffaelle owed their greatness to their own genius; and their art died with them. There has been nothing in the world like the art of Phidias, except the poetry of Shakespeare. The intellectual powers and perceptive senses of the Greeks must have been several degrees more refined than those of all preceding or subsequent nations.

Painting.

Massaccio.

The followers of Giotto had advanced the art from infancy in colour, composition, and expression; but in perspective, and light and shadow, they left it as they found it. Uccello had given symptoms of perspective, and Massolino da Panicale of light and shadow, until the appearance of Masso di S. Giovanni, a youth so immersed in study, so utterly absorbed in his divine art, that he neglected dress, health, food, sleep, and seemed only to be conscious of life when he touched a pencil. For this entire neglect of the humanities and comforts of life, the Italians, whose satirical turn is ever apparent, added *accio* to Masso (*accio* affixed to any word exciting associations of dirt or ugliness), so that Mass*accio* meant a dirty and neglectful man. Neglectful as he was, however, he was the immediate precursor of Raffaelle; and all the great subsequent painters studied him. Raffaelle borrowed from him Paul in Elymas, the Adam and the Eve in the Loggia, and other entire figures. Like Apollodorus, he opened the doors; and Raffaelle having passed through, never forgot his obligations. Ghiberti and Donatello formed his style; from Brunaleschi he learnt proportion; and though the finest antiques were not known in his time, he improved himself by studying such as were in existence. The airs of his heads are *Raffaellesque*, says Mengs; yet, would it not be more just to say, that Raffaelle's heads are *Massaciesque?* Raffaelle died the favourite of a court, loved, lamented, and in competence. Massaccio so excited the envy of his inferiors, that it is suspected he was poisoned at the age of twenty-eight, before he had fairly taken his ground. Surely, then, when Massaccio is praised for what must have been his own, it is not quite fair to term his excellence, that of a man who came after him, and perhaps owed it to him. His works are at S. Ambrogio and del Carmine in Florence, and St. Catherine in Rome. His heads are full of character, his drapery is beautifully composed, and his composition is unaffected, but his knowledge of the naked form is feeble and vulgar. Some of the heads of del Carmine are full of character like Holbein, with the same look of rigidity in expression; but he was a true genius, benefiting by his predecessors, going beyond them, and enabling those who studied him to carry the art to the highest point it ever reached in Italy. Pietro Perrugino, Leonardo, Raffaelle, and Michel Angelo, all studied and all were benefited by him. In the Palazzo Pitti there is a portrait of a young man who looks alive.

Ghirlandaio

After several names of great merit, we reach one who advanced towards the great era; we mean Domenicho Ghirlandaio, the master of Michel Angelo, a circumstance which alone is a passport to immortality. Fuseli says, that he was the first Florentine who added truth to composition by truth of perspective. The abolition of gold fringes in drapery may

Painting.

be dated from him; though his historical figures are little more than portraits well selected. The last important name of the first epoch of Italian art was that of Luca Signorelli, who had glimpses of real grandeur. His dome at Orvieto, where he painted the Last Judgment, has bold fore-shortening, with absurdities of an earlier date mixed up in it; but Michel Angelo adopted many of his ideas, as well as Dante's; and certainly the absurd assertion that he "disdained to look abroad for foreign help,"[1] is successfully refuted by this fact.

One can see how gradually art sunk after its decay into Gothicism; how gradually it advanced again to nature and common sense, and from common sense to elevation. During this first period the approaches to ideal beauty, imperfect as it was in Italian art, were gradual, and would have been longer in coming had not the discovery of the Apollo, and other ancient works, opened the eyes of all the great men living, and a spring taken place from Perrugino, Ghirlandaio, and the Bellini, which was soon visible in the works of Raffaelle and Michel Angelo. Leonardo seems not to have been smitten by the ancients to the same degree as the other two were. There is less obligation to any nation in him; and unquestionably few as are left of the effusions of his genius, they are more original than the Vatican or Sistine Chapel. What was there in the world to put us in mind of the Standard struggle or Last Supper of Da Vinci?

Oil painting.

But before proceeding, it may be as well to allude to the question of oil painting. It was long a supposition that Van Eyk discovered it, and that it was not known before; whereas, it was used in England in 1230, long before the time of Van Eyk. Cennino Cennini wrote a treatise on the technical practice of the Italian painters; he was a pupil of Agnolo Gaddi, who was a pupil of Taddeo Gaddi, who was a pupil of Giotto, who was a pupil of Cimabue, who was a pupil of the Greeks. There can be no question that from the mixture of oil with punic wax[2] as a varnish, the use of oil was known to the ancient Greeks, and that it was carried on to the tenth century, when the monk Theophilus[3] wrote his treatise. He positively describes how to mix the colour with oil instead of water, and how to boil the oil; and then we can prove its existence by actual documents in the rolls of the Exchequer in England (1239), and by the 23d of Henry III., wherein the king issues an order to "our treasurer Odo the goldsmith and his son, to be paid 117 shillings for *oil, varnish,* and *colors* bought, and for pictures made in the chamber of our Queen at Westminster,"[4] nearly two hundred years before Van Eyk. There can be no doubt that oil painting has never been unknown, even to the Egyptians; it has been forgotten and revived, but none of the periods of revivals are entitled to the honour of discovery. "Chaque nation a ses avantages, et ses désavantages," said a Frenchman to us, whilst shrugging his shoulders as a spout of water from a roof drenched him to the skin in Paris; and "Ogni nazione ha le sue virtù, ha i suoi vizi," says Lanzi. Every nation which confesses its vices, is sure to have justice done to its virtues. There is no Italian school, however good, which has not its errors, and none which has not its excellencies as well as its mistakes.

Florence was distinguished for fresco more than for oil painting. The Florentine style of design, in its best days, was always peculiar; the figures were long in proportion, their feet were small, and so were their knees; there was always a look, in Florentine design, as if the muscles of the body were suffering from a temporary knotted cramp; they were, in design, too circular, too elliptical, or too angular, and never seemed to have hit the exact medium between all three, like Phidias. Their colour was not rich, like the Venetians; their draperies clung too closely to the limb as if they were wet; they made an ostentatious display of the limb underneath; in fact their system degenerated into manner, and beauty seems not to have been a primary object in the Florentine school, any more than in that of their ancestors the Etruscans. At Fontainebleau, though the designs of Primaticcio were full of talent, yet they gave a very good idea of the excess of the Florentine manner.[5] The two great luminaries of Florence were Da Vinci and Michel Angelo. Da Vinci was less of a mannerist than the other great man. He was, in fact, the link between the meagreness of the first period of design, and the vulgar swing of the second.

Leonardo da Vinci.

Leonardo was born in 1452. He was a natural son, and had all the eccentricity, sloth and fire, weakness and energy, idleness and diligence of that class. A poet, a musician, a mathematician, an hydraulist, a mechanic, a modeller, and a painter; he excelled in all. Keen, eager, minute, searching and indefatigable, handsome in face, beautiful in person, tall in figure, athletic and skilled in manly exercises, a graceful dancer, a splendid horseman, and an harmonious singer; he equally delighted the people, infatuated the women, and bewitched the sovereign. And yet with all this vast power, the gift of his Creator, he was so deficient in concentration of mind, that he seemed to have no power of collecting its rays sufficiently long to make discoveries in any thing. He was the scholar of Verocchio, by whom he was infected with a lazy love of design in preference to the vigorous energy of using the brush. He passionately loved geometry, horses, and soldiers; and in his horses he never left nature like Raffaelle, Julio Romano, or Michel Angelo, but gave them their natural characteristics of fleshy nostrils and projecting eyes.

His two greatest works are his Last Supper, and his Battle of the Standard. The beautiful humility of Christ, the tender amiability of St. John, the powerful expressions of all the apostles waving to and fro in their attitudes, as if disturbed in their feelings, by the remark of Christ, that "one of them should betray him," prove the extent of his genius, and the depth of his perceptions. But even here, the bane of his existence, that disposition to experiment, has ruined the work, more from the consequences of his own preparations, than either time or damp. Such men are never regarded as steady lights by posterity; painting was only a portion of his occupations, and not the end of his life. One quarter of the lives of such men is spent in experiments; another quarter in putting them in practice; a third in lamenting their failure; and the last amidst the bitterest remorse, devoting themselves to their real pursuit, to satisfy the cravings of conscience and the reproach of the world. What has Leonardo left us in all his various pursuits to compensate us for the loss which accrued to painting? Geometry was as much a caprice of his extraordinary mind, as any other science. What has he left us in poetry, which poets could look up to? What in mechanics, that Watt could have founded on? What in music, that would have benefited Mozart? What in hydraulics, that would improve our shares in canals? The genius that composed such works as the Standard and Last Supper, need not to have shrunk from competition with Michel Angelo, young as he was. There is no doubt the world is always delighted to pull down an established artist by pushing up a younger rival in his face; but if you become irritable, and desert your

3 Lib. i. c. 18. Accipe semen lini et exsicca illud in sartagine super ignem sine aqua, &c. Again, "cum *hoc oleo* tere minium, *super lapidem*;" and again, "accipe colores quos impone volvens, *texens eos* diligenter cum *oleo lini.*" (*De omni Scientia Artis Pingendi.*)

4 Rot. Claus. 23d Henry III. Walpole's *Works*, vol. iii. p. 16.

5 In 1814, the writer saw the remains. There was a naked youth over one of the gateways, which had all the peculiarities of this school.

country from disgust, men only laugh; whereas the sound principle is, Laugh at the world, stay in your country, and work harder than ever.

The fact is, that such men as Leonardo are great geniuses, but not the greatest. The evidence of superior genius is the power of intellectual concentration. Such powers had Newton, Milton, Bacon, Locke, Watt, Michel Angelo, Napoleon, Raffaelle, Titian, Rubens, Vandyke, and our own Reynolds. Such men only are examples, and not beacons; such men only are blessings to their species. As a specimen of his extraordinary caprice of character, his want of perseverance and his notions of the most elaborate finish were at least equal; he took four years in painting one face, and then said it was not done. His children are exquisite; but his women have an air of modesty to conceal meritriciousness, and his oil-works are far from models of excellence, the over-wrought finish being hard. There is always in his expressions an air as if they were set in enamel, and could not relax. The picture, in our national gallery, of Christ and the Doctors, is a celebrated work; but why should Christ, who disputed with the doctors at twelve years of age, be larger in person and head than the doctors who are sixty? And why should Christ be like a woman in men's clothes, and look out of the picture, and talk with his fingers to the spectators, instead of being, as he was, a fine boy of twelve years old, handsome, intellectual and angelic? We should like to have heard Leonardo's reasons, if he had any, for such an apparent absurdity.

In design, and tempera or fresco-painting, Da Vinci was great; but in oil pictures he is false in taste, petty in execution, and unskilful in backgrounds. By his depth of light and shade, and also of colour, which gave an impulse to all Italian art, he had a sense of beauty which greater steadiness might have brought out to perfection. But when a man flies off from painting to make a lion, which will walk by machinery, to meet the king of France who approached Milan, to stand upon his hind legs without human help, to open his own belly, and show the king of France his arms inside it, what could be expected from his talents, great as they were? Nowhere does his character show itself more conspicuously than in his treatise on painting; in fact it is not a treatise, but a collection of separate disjointed thoughts, like the recipes of a cookery book. It is very easy to put down your thoughts as they occur without arrangement; but the difficulty is, to collect them for the illustration of a principle like Fuseli or Reynolds. Every man can put down separate thoughts, but every man has not the power so to arrange them as to throw light upon an art. Leonardo dissected and drew finely; but there was a meagre common-model style in his figures, a want of perfect construction, as if men had never worn clothes. On the whole, this illustrious man cannot be referred to as the head of an epoch. He was a component part of it, but not like Michel Angelo or Raffaelle the great engineer. What he did in painting made one lament that he had not done more. "An artist," says Reynolds in his letter to Barry, "should bring his mind to bear on painting, from the moment he rises till he goes to bed; and if his mind be calm and undisturbed by other objects, he will find it quite enough to fill up life, if it was longer than it is."

Michel Angelo.

No man could be more opposite to Leonardo than his great successor Michel Angelo, patient, laborious, virtuous and indefatigable, painter, architect and sculptor; he left a work in each art that advanced the rank of his country. To turn to such a character, is a relief and a blessing. In him the aspiring youth contemplates the result of conduct totally the reverse of that we have been considering. Solitary, and highly gifted, despising the subterfuges of society, he lived alone; and in addition to his genius he was a great moral being. Brought up by the liberality of Lorenzo de Medici, admitted freely to his table with the illustrious men of the day, Michel Angelo had every advantage in early education. He came, too, when he was wanted; when ancient literature and ancient art were breaking through the obscurity which had overwhelmed them, and the discovery of printing was scattering their beauties throughout Europe. Men's minds were roused up with wonder and delight at every fresh discovery. Painting, architecture, poetry, and science were hailed with a gusto which nothing can account for but the misery of the ages that had passed.

Michel Angelo, after his day's study in the gardens which Lorenzo had opened for the youth of Florence, retired to the coins, cameos, and fragments of the palace. With his acuteness, energy, and perception, it is not wonderful that he soon perceived the inferiority of the forms of his master, in comparison with the full beauty of the form, the result of perfect construction in the antique. He corrected with his boyish hand the narrow meagreness of Ghirlandaio; and announced, thus early, that self-will and vigorous decision, which enabled him subsequently to accomplish whatever he undertook. Here was the germ of that mighty power which placed the Pantheon in the air, as he predicted and realized in the dome of St. Peter's. Here was the embryo fearlessness, that brought him through the vast ceiling of the Sistine Chapel in fresco, though when he began it, he had never painted in fresco before. Michel Angelo was one of those rare beings who are wanted when they come, and have opportunities put in their way adequate to develope the powers with which they are gifted. Julius II. was as wonderful a man as Michel Angelo; and they mutually inspired each other. What Julius willed, Michel Angelo was as ready to perform; and what the inspirations of Michel Angelo's genius suggested, the vigorous pope, whose fine old venerable head a helmet would have suited better than a tiara, had comprehension to value. They were both fierce, both self-willed, both proud and haughty, both independent and ungovernable. If Julius wished what Michel Angelo was in no humour to do, he would not do it; and if Michel Angelo wanted to execute, on sound principles of art, what the aged pontiff did not comprehend, he would do it, in spite of denunciations of banishment, or threats of displeasure. They were made for each other, they understood each other, and they were attached to each other; they quarrelled, became friends, and quarrelled again. "When will the ceiling be finished?" said Julius, as he trod on the scaffolding with a stamp that made the boards tremble, after climbing to the top, where the great artist lay on his back on a mattress, hard at work, painting with vigour. "When I can," said Michel Angelo, irritated at the interruption. "When thou canst," thundered out the pope; "Art thou minded to be hanged?"

This was the man for Michel Angelo. Conscious of his age, conscious that death followed him wherever he went, he began, proceeded with, and finished all he undertook, as if he had not an hour to live. By his perpetual watching, he hurried Michel Angelo through the ceiling of the chapel in twenty months, a time by no means equal to that which ought to have been devoted to it. The hurry is visible in the fierce, rapid execution; and that which was entirely owing to the impetuosity of his old patron, has been attributed as a merit and a principle to the great painter. Such is the infatuation of praise when a man is really great. Of this astonishing work, it seems that enough can never be said; though language has been exhausted to do it justice. Fuseli was the first who cleared up the mystery of the composition, in a style that places the commentator on a level with the inventor. "It exhibits," he says, "the origin, the progress, and the final dispensation of theocracy." But Fuseli's character of Michel Angelo is overdone. It is an effort to express the deepest feelings in the strongest language; and in all such efforts the language invariably becomes inflated and turgid.

In comparing this illustrious sovereign of modern design with Phidias, or the Greeks generally in the naked figure, he must unquestionably yield to them the palm. Michel Angelo often perplexed his limbs with useless anatomy; it must not be denied, and cannot be refuted, that he did not always clear the accidental from the superfluous. If the principle be a sound one, namely, "that any two parts of a body bearing comparison must keep a consistency throughout, similar in essence and similar in development," then is Michel Angelo grossly inconsistent; because if the spine of the ilium in front be covered fully by the muscles around it, so ought the spine of the scapula behind to be equally covered. If the former be, and the latter be not, then the figure is inharmonious and inconsistent, and what Phidias would never have tolerated. Now the figure of Michel Angelo's Christ standing with a cross, has the spine of the scapula prominent and bony, and all the muscles shrinking from it, the characteristics of a thin man; whilst the spine of the ilium of the same figure in front, is entirely covered by the muscles around it, the marks of a muscular and fleshy man. What authority had Michel Angelo in nature or antiquity for such inconsistency? These are the excesses which bring dissection into contempt, and which induce anatomists to doubt whether the Greeks dissected or not, because they were never guilty of such absurdities, and because they had too much self-control to make that an end of art which was but a means of the perfection of art. And yet Vasari calls it "mirabilissima." This figure and the Lazarus in Piombo's, as well as several figures in the Last Judgment, are justifiable grounds for asserting he was not equal to the Greeks in the naked figure; though in the conception and arrangement of a vast whole to illustrate a grand principle, he approaches but does not surpass the Parthenon in its glories. In the form he must not be compared to the Greeks; gigantic as he is, he was decidedly inferior.

Michel Angelo's line is by no means "uniformly grand;" and his women may be "moulds of generation," but certainly not of love. His infants may "teem with the man," but they have nothing of the infant. His men may be a "race of giants," but they are brutal in expression, fierce in action, and distorted in position. It is useless in a rapid and general view of art to go over ground which has been so often gone over before; to talk about the prophets and sibyls, after three hundred years' enthusiasm, is worse than useless. Europe knows the awful grandeur of one or two of them, looking like beings to whom God has spoken, and who have never since ceased meditating on the awful voice.

The style of Michel Angelo has been called the style of the gods; but if majesty without pretension, humility without feebleness, power without exertion, and an awful presence without vulgar assumption, be the characteristics of a god, what figure of Michel Angelo's deserves that appellation? Is it in the bullying defiance of Moses? the twisted tortures of Jonah? the cramped agonies of the sleeping Adam? or the galvanized violence of the ornamental figures at the tombs? It must be admitted, that the *Pensoso-Duca* is majestic and silent; but this is an exception, not an habitual characteristic. "Michel Angelo's mind," says Reynolds, "was so original that he disdained to look abroad for foreign help." Disdained! Why there is not a prophet, a sibyl, or a naked figure in the whole chapel where the torso cannot be traced. And what are the works of both Michel Angelo and Raffaelle, but improved completions of all that their predecessors had done for a thousand years in barbarism and obscurity? Shakespeare's plots are all borrowed; Lady Macbeth is not his own; that hideous expression "know Macduff was from his mother's womb untimely ripped," is Hollingshed's. But what of that? It is the new thoughts he puts into them, which give him claim to the sympathy of the world. Phidias and Raffaelle have one great and decided beauty in their works; their figures, whether in action or expression, always look as the unconscious agents of an impulsion they cannot help. You are never drawn aside from what they are doing by any appearance in them, as if they wished to make you consider how very grand they were, or how very gracefully they were moving. They seem impelled by something they cannot control; their heads, hands, feet, and bodies immediately put themselves into positions the best adapted to execute the intentions wanted; whereas *often* in Michel Angelo, and *always* in his imitators, there is a consciousness as it were in his arms and limbs, which destroys all idea, as if his figures were the unconscious agents of an impulsion they could not help, and which acted by means of the will on the muscular system.

It is an inherent principle of life never to disturb itself for grace, or for any other object either in action or repose, not immediately the natural consequence of the impulsion which moved the body. Style in design is a *result* and not a *cause*. Whatever object is represented in painting or sculpture, the intentions of God in its bodily formation should be ascertained; the means which God has bestowed on it to enable it to execute its only will or gratify its own instincts, should be investigated; and then the aberrations produced by time, accident or disease, or other causes, will be clearly known, so that he who takes upon himself to represent any object in painting, will be able to distinguish accident from essence, and shew the object in its essential properties of body as God first created it. The external form in that body will then be *essential*, and the result of its completion in art will be *style* in design. There are certain inherent principles of our common nature to which all bodies must yield, viz. that compression and extension must have different effects, and so must repose and action. If a great artist represents a figure and makes its parts the same in either case, he must be ignorant of nature or above its simplicity. No doubt, the conception of an idea may be so grand, the beauty of a character may be so angelic, the pathos of an expression may be so deep, that errors or inadequacy in the mode of representation may be overlooked or forgiven; but in order to bring the art to the perfection to which the Greeks brought it, there must be nothing to forgive or to overlook. An idea or conception being the nobler part of the art, we may, in our common conviction of human frailty, *overlook* any inadequacy in the means of imitation; but the very admission proves there must be something to be overlooked and something which, we have a notion, has not been adequately represented.

An art the modes of which to convey thoughts, being the imitation essentially of natural objects, ought surely to have the imitation perfect, because the imperfection of the means has always detracted from the impressions of the thought. Poets are not endured if their grammar is bad, or their language defective; and why should drawing, form, colour, or light, shadow, and surface, the grammar of art, be excused more than the poets'? Because the simplest imitation is at once recognised as the imitation of the prototype, why should facility of imitation be any excuse for defect? Ah, but it's the *grand* style. Yes, the grand style of Europe for the last three hundred years; but was it the grand style of the Greeks? Certainly not; their grand style was nature elevated not violated, with none of her inherent bases of life altered a hair's point, none of her essential details omitted, and none of her essential principles overwhelmed by useless detail.

When you see an outline like iron, that is the grand style. When hands were twisted, heads distorted, one leg up, and the other so far removed from the body, that you may question if it will return, that is the *grand style*. All this absurdity originated with Michel Angelo; and though he is not answerable for the excesses of his admirers, there must be

Painting.

something erroneous if every imitator has led to such extravagance from Goltzius downwards. Michel Angelo was a tremendous genius, and his effect on the art was vital; but he did not like the Greeks suffer the unalterable principles of life to keep in check his anatomical knowledge. This was an error, because we can imagine no beings, and no world where malleable matter is not influenced by the common principles of the solar system, or where any creatures composed of bones, muscles, tendons, and skin, must not yield to the laws which God instituted for their government when he created them.

Thus Michel Angelo often overstepped the modesty of truth, and gave a swaggering air to his figures. Every figure of his looks as if he was insulted and preparing to return a blow. If they sleep they seem as if they would kick; if they move when they are awake, they seem as if all their muscles were cracking. We allude particularly to the naked figures; Jeremiah and the Duke are exceptions, but they are only exceptions. Fuseli observed that Michel Angelo was the *salt of art;* but it would have been more just to have called him the *pepper*, because very little indeed will do for a seasoning. In poetry of sentiment the Medici tombs would perhaps have competed with Phidias; for Michel Angelo being a painter as well as Phidias, he combined in his sculpture a knowledge of effect. In selection of subject and daring execution of hand, perhaps the Sistine Chapel might equal the great works of painting amongst the ancients; but in naked representations *it cannot be compared to it.* The Elgin marbles had not then enlightened the world. The due subordination of all science to nature had not then been so exquisitely seen; the due combination of life without meanness, and of abstraction without losing sight of life, were not so apparent in the great works of ancient art which were found before this period. Had Michel Angelo seen the Theseus and Ilyssus, Jupiter's breast and horse's head, he would have felt the difference between the muscular swing of a blacksmith, and a hero naturally born powerful, without his muscles being distorted by manual labour; and that a hero might be elevated and yet simple, fleshy without fatness, and muscular without being skinny. Michel Angelo has been called the Deity of design; but he was rather the Devil. One can imagine the consternation of Phidias and his pupils, if suddenly at Olympia the galvanized figures of the tombs had been let down through the roof, whilst they were preparing the Olympian Jupiter, with his quiet, solemn, steady, thinking, peaceful, awful look.

Reynolds says he prepared the way for the sweeping outline of Rubens; but how many thousands has he ruined? What is the excellence of the Last Judgment? Is there any evidence of power in arranging a whole, like Rubens, Titian, or Tintoretto? Is there any application of any principle of our nature by the due combination of variety and repose? Is it not a mass of separate groups, vulgar in design, academic in action, and demoniac in expression? Is the Christ worthy of Goltzius? Surely it would have disgraced him; and then what devils! Are these the fallen angels of heaven? they are the legitimate offspring of hell. Are these the beings whose glory was obscured, not extinguished? whose majestic forms existed, though in ruin? whose beauty was only disturbed by passions, not destroyed? who were the same grand, heroic, terrific beings as ever, but scathed by lightning, singed by fire, dingy from darkness, lacerated by thunder, their splendour sparkling through the horrid obscurity, in which they meditated revenge? To give them mouths like wolves, ears like asses, noses like pug-dogs, and tails like monkeys, with feet cloven and misshapen, was not to represent a fallen angel, but a deformed monster. Though evil, they were beautiful.

"—— Their forms had not yet lost
All their original brightness."

"What matter where, if still I be the same?" says Satan. Could such a sentiment have ever been uttered by the wretch who is dragging a figure down to the bottomless pit, in a way delicacy forbids one even to think of, much more to write or to paint? Michel Angelo's demons would not only torture the damned, but feed upon their bodies.

It is clear, however, that there *was* a time when he was not so exaggerated. The holy Family, in sculpture, brought by Sir George Beaumont from Italy, is playful, natural, simple, and beautiful; it is in fact a divine work. Perhaps the violence of Julius in hurrying him through the Sistine Chapel, and the necessity of painting with tremendous exaggeration, on so large a space, got his hand into a fierce power that it never lost. Painting on grand ceilings is like talking in large theatres. He never entirely finished any thing; he left no grand pupils, like Raffaelle; he assisted the humble, but never instructed the gifted. The figure of Lazarus in our national picture, especially the hand and thumb that press the shoulder of the attendant on the left side, is certainly by him; and if it be compared to the timid painting of the Christ, the spectator will be convinced of it. In fine, Michel Angelo was a great genius; but let the students of Europe be assured that his style has been grossly overrated; let them banish his works from their eyes, and substitute the Theseus and Ilyssus, and the real grand natural style of Phidias will soon exclude the satanic Etruscan, and violent anatomical distortions of Michel Angelo. He may be and was a giant in art; but Raffaelle was an angel, and Phidias a god.

Bartolomeo

The next Florentine of power was the monk Bartolomeo. He studied under Rosselli, and Leonardo aroused and excited him; he was grand in colour, light and shadow, and execution, surface, and character. In the Louvre there were works worthy of any hand, any competitor, or any genius. He had the honour of advancing Raffaelle; he invented the lay figure, and made the proper use of it; he never put drapery on it till he had drawn the naked figure first, so that the naked parts affected the forms of his folds; he had great depth, grandeur, and a certain wildness of air; he drew finely, and his tones were solemn and elevated. Wilkie speaks with the highest enthusiasm of his Assumption of the Virgin. It is impossible not to feel the deepest interest in Bartolomeo, and not to be astonished that he did not found a school, and head an epoch. Such things, however, are never done by the mere influence of talent; the character of the man is principally though not wholly the cause. He painted a S. Sebastiano, which was so beautiful, that it became a favourite of Italian ladies. He was ordered to adorn the great hall of council at Florence, as Da Vinci and Michel Angelo had done before; but as if a fatality attended that hall, he died without going further than the designs. This is curious. Da Vinci designed the Standard struggle; Michel Angelo the group of soldiers alarmed by the trumpet, and dressing themselves; and now Bartolomeo began his designs, and died in 1517, without completing them. Bartolomeo was a great artist. His method was first to draw the naked figure, then clothe it, then paint the whole picture in light and shade in oil, and then tone and colour, guided by the tremendous depth of his first impasto painting.

Andrea del Sarto.

Andrea del Sarto is another name enthusiastically overrated by Vasari. He might be called Andrea senza errori; but what genius "senza errori," ever enchanted the world? Give us the vigour of Michel Angelo, with all his violence, the dash of Tintoretto with all his caprice, the colour of Titian with his want of drawing at first, the sweetness of Corregio with his namby-pamby men, the composition of Rubens with his flabby women, the expression of Raffaelle with his hardness of effect; but spare us from that poet, painter, musician, or moral character, who is so perfect that he must be admired without the gusto of finding fault; above all, spare us from the Grandisons of art. Andrea was

one of those to whom talent is more applicable than genius; whatever excellence he attained, he would have never attained to that degree, but for the existence of his superiors. The greater part of the works attributed to him in England, are copies by his pupils which he retouched.

Decline of the Florentine school.

After these great men, it would be useless to detail the decay of the Florentine school; it yielded to the circumstances of the time, and the misfortunes of the Medici. The continual political squabbles turned men's minds from art as in ancient Greece; but the great want of course was the want of genius, which no efforts have since been able to rear. Though the style of the Florentine school was not so pure as that of the Roman, it led the way in a noble manner, and kept side by side with it; they benefited each other. Leonardo gave an impulse to art; and though from the caprice of his character, he did not complete the impulse he had given, and was more the cause of greatness in others, than the man who established his own, yet the art is indebted to this highly-gifted man, who had an effect on Georgione, Bartolomeo, Raffaelle, and Michel Angelo himself; and gratitude is due to his genius. This great school was brought to utter ruin by what Lanzi calls the Cortoneschi, or pupils of Cortona, where art had degenerated into mechanism, and thoughtless, endless, and sprawling groups. The descendants of the Medici breed had more disposition than power to patronise, till Leopold reigned in 1765. The academy was renovated in 1785, and once more in 1804; but these renovations end in nothing. The great men were passed without these conventional distinctions; the little ones who came after, live only by their embellishment. Boys are educated to draw tolerably well, to colour with tolerable harmony, to invent tolerably insipidly, to become intolerable painters, accomplished academicians, to die, be buried, and decay; and thus leave room for another race as intolerably imbecile in art, as their illustrious performers before them. It is quite absurd to read in Lanzi, always at the end of the epochs of a school, "Decadenza dell' arte, e *fondazione dell' academia per avivvarla*;" "decay of art, and foundation of an academy, to give it life." But after a few galvanic twitches it stretches out its feeble legs, gasps with an expiring quickness, gives a trembling of its eyelids, which it opens once more, stares with a fixed look, sighs deeply, and drops its jaw for ever. Then come the vain efforts to restore circulation, then the delusive assurances that it is still living; then doctors and nurses dress up its helpless head with laurel, and put some abracadabra on its cold breast; but all won't do for it's gone and there is no hope. Such have been the results of the academies. Genius fled at their foundation, and left them useless bodies without soul, life, or circulation. The sovereigns of Europe will at last find out that no academies should go further than schools; and till they do, the end of art will be forgotten, in a vain contemptible struggle for its conventional distinctions.

Roman School.

The three leading lights of art as schools, are the Florentine, the Roman, and the Venetian. The Parman must in spite of all the beauty of Corregio, be considered as the beginning of corruption. The other schools, the Modenese, the Cremonese, the Ferarrese, Genoese, and the Piedmontese, are but different branches.

Raffaelle.

The glory of Italian art is Raffaelle. Had he been born in Greece, and qualified by a Greek education, he would have been as great in painting as Phidias was in sculpture; but the education of all the Italian artists was imperfect, and they seemed to be grounding themselves, (even Raffaelle himself,) on the meagre style of the early painters. The discovery of ancient statues in some degree opened their eyes, but they were not, like the ancients, gradually prepared for such perfection, nor was Raffaelle himself ever skilled in those perfect principles of beauty, as applied to the naked figure, which distinguished the Greeks. Wonderful, amiable, and gentle creature as he was, the reverse of Michel Angelo in every way, who proved himself decidedly the inferior man. In all his endless inventions, a single repetition of himself, even in the folds of a drapery, is not to be found; he was not like Titian, an exquisite colourist, but his colour is always agreeable, though not distinguished for light and shade; and his groups are never obtrusive, though not remarkable for aërial perspective. Every object keeps its place; though no face of his can compete with the beauty of the ancients, his women always enchant; his great power was character and expression, and telling a story by human passions and actions; in these he was unrivalled in modern art, and not surpassed by the ancients. His father being a painter, he was bred up in the art; and his master Perrugino, was a great man in his way, though somewhat of a Goth. In style, therefore, Raffaelle lost time with him; but could he have gone in early life to such a school as Sicyon, there is no knowing to what a pitch of perfection he might have carried the art. His latter excellence is entirely owing to his own sense, based on the antique; for most of what he learnt from Perrugino he had afterwards to unlearn. He entered the Vatican at twenty-five, and died at thirty-seven. What then must have been his diligence, his devotion, and his genius. In any history of painting, at this time of day, to talk of the subjects of the Vatican, or the Madonnas, so often copied, so often engraved, so often seen, so often praised, would be trespassing on the temper of the reader. His character, as well as that of his art, was the very converse of Michel Angelo. Michel Angelo envied his equals, was kind to his inferiors, and always insulting to his superiors; whilst Raffaelle was kind to all, and the idol of the society in which he moved. Michel Angelo associated with no men but admirers. The consequence was that his life was written by his flatterers Condivi and Vasari, a great portion, perhaps, delicately insinuated by himself; and, as might be expected, they have sacrificed Raffaelle to the Dagon of their idolatry. Vasari insinuated that Raffaelle was greatly indebted to Michel Angelo; and Reynolds following Vasari and Condivi, goes farther than either, asserting that Raffaelle owed his *existence* to Michel Angelo. Was there ever such gratuitous assumption? If it means any thing, it means that but for Michel Angelo, his genius would never have been developed. Is such an absurdity worthy of Reynolds' understanding? Surely not, and in fact it can be made clear that Raffaelle did not owe his existence to Michel Angelo. If he owed any thing to that great artist, he owed the corruption of his own pure style. After the Capella Sistina was opened, Raffaelle, bit like every body else by its heavy, cumbrous, vulgar, broad, and circular design, immediately tried it; but it did not suit his beautiful nature any more than it would have suited the elliptical beauty of the heroic forms of Greece.

What does Reynolds mean when he says, that "Raffaelle had more taste and fancy, Michel Angelo more genius and imagination?" If genius be nothing more than the ordinary faculties of men carried to a greater pitch of intensity than ordinary men possess them, wherein had Michel Angelo more genius than Raffaelle? Their geniuses were both equal; but the road which each took for the exercise of his genius was different. Raffaelle excelled in expressing the passions; Michel Angelo in sublimity of character, independently of all passion and emotion. Though the materials of Raffaelle's art are generally borrowed, are they more so than Michel Angelo's? Is not Michel Angelo as much indebted to Luca Signorelli and the Campo Santo, for his choice of subjects in the Sistine, as Raffaelle is in the Vatican? This does not invalidate their genius; whilst their predecessors were the root, the stem, the leaves, and the bud, they were the full blown flower. Michel Angelo was a great genius, and so was Raffaelle; but each owed his genius to a power totally independent of the other. Their geniuses were equal, their temperaments different. Raffaelle was at the mercy of pleasure; Michel Angelo disdained it:

Raffaelle was made for society; Michel Angelo despised it. In Raffaelle's works there is a geniality of soul with which every man's and woman's heart beats in sympathy; whilst we have no sympathy with the characters of Michel Angelo who overwhelms our imaginations, but never touches our hearts. We are awed by his sibyls, but we could never think of loving them; and his demons are surely unworthy of the fiery solitudes of hell. How could Ariosto say of him,

"Michel, piu che mortel,
Angel divino;"

and then herd up Raffaelle with Sebastian and inferior men; Michel Angelo was perhaps the more moral man of the two, but not the greater painter.

Vasari and Condivi would never have been allowed to publish their falsehoods, as Lanzi says, had Raffaelle been living; but where were Julio Romano, Luca Penni, and Polidoro, whom Raffaelle had raised from a mason's boy to a great painter? Where were they? where were his "dear pupils?" "Let no man," says Johnson, "look for influence beyond his grave." Vasari asserts that Michel Angelo, in flying to Florence, when he quarrelled with Pope Julius II., left the keys of the Sistine Chapel, which he was then painting, to Bramante, Raffaelle's uncle, who dishonourably let in Raffaelle; and that the latter, on seeing the grand design of the prophets, changed his whole style. This absurdity was current in Europe for two hundred and fifty years, till Lanzi, with his usual acuteness, opened the eyes of the world. Would any one believe, that when Michel Angelo fled to Florence, it was in 1506, years before Raffaelle ever entered Rome, and four or five before the chapel was ever begun or painted? It may be presumed that Raffaelle did not surreptitiously derive any advantage from works four years before they were conceived or painted; and we conceive that Bramante could not give Raffaelle the keys to open a door which was never locked, especially as Michel Angelo did not leave any keys, if ever he left them at all, till four years after the time Vasari dates as the period. The prophet Esaias which Vasari says shewed an alteration of style in consequence of the stolen views of works which were not in existence, was painted one or two years before Michel Angelo touched this very chapel. So much for Vasari's sacrifice of Raffaelle to the great Dagon of his idolatry; and so much for Reynolds' absurd and unthinking assertion, that "but for Michel Angelo, Raffaelle would never have existed." Vasari's is a delightful book, and all his principles of art are sound, for they are the result of conversations with the greatest men; he was most intimate with Michel Angelo, and Titian, and all the great artists of the day, and constantly in their painting-rooms, at their tables, and in their society.

In the first years of Raffaelle, his feeling was so completely Perrugino's, that it was almost impossible to distinguish their works; though there is a difference in feeling, and that difference is in favour of the pupil. In the Louvre were three of his early works of cabinet size. The Annunciation was one of these; and more grace, innocence, or sweetness, were never put on canvas. Raffaelle's pencil seemed always to melt when he approached a woman or an angel. What an age of genius this was, and how nearly all the great men seemed to come together. Da Vinci was born in 1452, Bartolomeo in 1469, Michel Angelo in 1474, Titian in 1480, and Raffaelle in 1483.

In a rapid and concise history of art to detail the inferior names, who gradually by little and little, conduce to the ultimate expansion of genius, is impossible. A historian of this description has only time for leading points, or headlands in the voyage; he has not leisure to dive into every little cape, bay, and projection, which by degrees, push the mainland into the ocean. The older painters of the Roman school will not add much to the interest of the art; and a fair estimation of Raffaelle and his glorious school, is much more likely to benefit the student, and instruct the general reader. It is not, on the whole, morally just; but many eminent men become thus swallowed up in the blaze of their successors. As Shakespeare nearly deadens all feeling for previous excellence, so does Raffaelle, though Shakespeare, Michel Angelo, Raffaelle, and Titian were all indebted to their predecessors.

If Julius was adapted for Michel Angelo, Leo X. was peculiarly so for Raffaelle; though Mengs says that the honours and indulgences he received from Leo, made him luxurious and idle, and that he was not so industrious as during the short reign of his first patron Julius. Yet his rapid advance from the first picture he painted in the Vatican, to the Heliodorus, is extraordinary; and, as according to Vasari, he sent artists to draw for him in Greece, there is no doubt that he had a sketch of the pediment of the Parthenon, before it was blown up, and that the Heliodorus is but a skilful adaptation of the Ilyssus. He was so much overwhelmed by employment and honours, that his latter works in the Vatican were wholly placed in the hands of his pupils, and carried on with the spirit of a manufactory. He was then appointed architect to St. Peter's at the death of St. Gallo, which distracted his thoughts. Incessant application, and incessant thinking of course weakened his delicate frame, nor did the capricious and harrassing attendances on such a court increase his strength; added to which the maddening love of women for one so highly gifted and so handsome, his own devoted passion for Fornarina, and the endless demands on his brain, brought him to the grave at thirty-seven, absolutely borne down, like Byron, by excitement of every description, nervous, bodily and mental. This is the way with the world; they kill a favourite by kindness, and an offender by cruelty.

In some life of him an attempt was made to prove that he caught cold by hurrying from his work to the palace at the Pope's order, and standing while in a profuse perspiration in a draught. But that is no refutation of the previous causes; the question is, what prepared him to be killed by such a cause? Incessant work and dissipation; no painter can do both. Of course princes must be obeyed at any expense; they seem to feel little for their dependants, as if in revenge for being themselves deprived of so many enjoyments by ceremony and etiquette. Napoleon used to take great delight in never suffering old German maids of honour with fifty quarters in their arms to sit in his presence.

His last work, according to Mengs, was his Transfiguration in oil, a work deficient in masterly execution, and having a laboured look of smoothness. In drapery, in character, and in expression it was fine; but in the Louvre it looked small. By the side of Corregio, it seemed hard; by that of Titian, raw; by that of Tintoretto, tame; and the Christ's head was not equal to Corregio's at the National Gallery. It was not an example to hold forth to a young man as faultless. The Cartoons at Hampton are finer in point of execution alone; they are his finest works for all the requisites of art. He was not restrained by designing for tapestry; his genius was put forth with a Venetian power of brush; and there are heads equal to any, especially the frightened woman's head in the Ananias, in these wonderful works.

In beauty he was far inferior to the Greeks; in form he could not approach them; in composition he was perfect; in expression, deep; and in telling a story, without a rival. Taking into consideration all the great men in modern art, this young man, not highly educated like Rubens, must be placed on the throne, till one arises who shall have what he had not, in addition to his own perfections; and that young man will probably arise in Britain. He was an extraordinary creature; modest, timid, and amiable; affectionate to his equals, and gentle to the highly-born, his premature death gave a shock to Rome, which those only

can estimate, who know the depth of Italian sensibilities. But did he die too young? Not at all. He might have decayed, or he might have become more luxurious and more neglectful. No man dies too young who dies with all the sympathies of the world unexhausted about him. The *furor Raphaelis* is the best species of fury that can seize a young student. He has no manner, no affectation, no vice, no grand style; all is simple, natural, and unaffected. His women are creatures of gentleness and love, though none are perfectly handsome. Perhaps he was more adapted for the characteristic heads of apostles than the naked forms of Greece; in fact he was a great Christian painter, and seemed born to extend the influence of Christianity by his art.

His father being a painter, he began early of course, and at sixteen, had painted a picture at Castello, the composition of which was in advance of the age. At seventeen he painted another of the Virgin and Child. In the Sacristy, at Sienna, he assisted Pinturichio with designs; in 1504, he went to Florence, where Michel Angelo and Da Vinci were making a great noise with their cartoons for the hall; he studied both, and improved his perspective and colour, in connexion with Bartolomeo. When Bramante, his uncle, who was architect to the Pope, advised his Holiness to send for Raffaelle, the pope consented; and in April 1508, Raffaelle entered Rome, and was admitted into the Vatican.

From the continual occupations of Raffaelle in his art from boyhood upwards, he could not have had a classical education to any great extent. He knew a little Latin, as all Catholics did; but he was intimate with Bembo, Castiglione, Ariosto, and Aretino; and these men must have helped him in historical or philosophical knowledge, or moral allegory, for the completion of his great works. Raffaelle left a noble school; and as soon as grief for the loss of their master had subsided, his pupils set about completing the works he left unfinished. The battle of Constantine was done by Julio Romano and Perino del Vaga. As Raffaelle lay in state, the Transfiguration was placed at the head of his coffin.

Julio Romano.

Julio Romano was the most eminent of his pupils. With vast poetry of mind, he did things in a style of execution, which renders him the purest poet in his art. His sun setting, and moon rising over our heads, in the Palazzo del T, is nowhere equalled or approached. Though he put forth his genius at Mantua, he was a Roman in practice, and to Raffaelle owed the elements of his art. His colour was crude and his execution harsh; yet no one can fail to see in his works, the real poetry of painting.

Polidoro.

Polidoro was another great man of the same school. He was originally a mason's boy, and used to prepare the walls for fresco; but he got interested in seeing the young men at work, tried to draw himself, and Raffaelle having assisted him, he became an eminent painter.

It is interesting to reflect on the affection with which Raffaelle was surrounded. He never went to court without being attended by fifty gallant artists. Little must he have made others feel his superiority; and for once a man of genius seems to have made envy smile. Though there is an instinct in the world, the moment a man of genius appears, yet it depends upon himself whether he is received as a blessing or an annoyance. Mankind will assault the man who attempts to command by superiority, instead of leading by courtesy; but they will hail him let his superiority be what it may, who seems willing to help his inferiors with kindness, or supply their want of knowledge, as if they were doing him a favour to listen. The whole of this is based on goodness of heart, tender sympathies, and a consciousness without the appearance of conceit.

Decline of the Roman school.

The glory seems to have gone from the Eternal City after Raffaelle's death. In 1527, Rome was stormed and taken by foreign soldiers. The savages bivouacked in the Vatican, and injured the frescoes by their smoking and fires. Sebastian del Piombo attempted to repair them after the soldiers were gone; and Titian, when in Rome, not knowing Sebastian, actually asked him who had been spoiling those beautiful heads? The art went on sinking rapidly till 1595. Raffaelle had been dead seventy-five years; Giorgione, eighty-four; Corregio, sixty; Michel Angelo, thirty; and Titian, nineteen. When the usual apprehensions of getting on a lee-shore seized the patrons and the artists, and the usual signal of distress was hoisted, Muziano, a pupil of Titian, founded St. Luke's Academy in order to raise a new batch of Raffaelles and Corregios, and save the noble vessel. The only man who since dazzled for a moment, was Michel Angelo Caravaggio. He had great and original talent, though founded on common nature, without any abstract notion of form, any conception of beauty of women, or any refinement in anything. With a sledge-hammer for a pencil, he seemed resolved to batter down all opposition; and by fierce extremes of light and shade, bearded men, dead Christs, and Transteverine beggars for apostles, he founded a school, got a character, and raised a name, which cannot be forgotten in the art of Europe.

Lanzi seems to class in the Roman school every body who practised there for the last three hundred years, but that is not fair. On this principle, all the Flemings, Dutch, Germans, Russians, Spaniards, and English, may be of the school, because they studied there; and Rubens, Vandyke, Velasquez, the Caracci and their pupils, as well as our Reynolds, were, on the same principle, of the Roman school. About the seventeenth century, this eminent school, in spite of the academy of St. Luke, went on declining. Birth, destruction, and reproduction seems to be the principle of every thing physical, but not of moral or mental powers. Lanzi attributes this decay to any cause but the right one; namely, the *absence of genius*, the great primary cause, and which no academy can ever supply.

Cortona, Bernini, and Sacchi.

Cortona, Bernini, and Sacchi, were the heroes of this day; and at a later period appeared Carlo Maratta. Raffaelle became to him a substitute for nature; though in 1689, he gave sufficient tone to art, to induce Clement XI. to employ him. But here, as well as elsewhere, genius was wanting. Carlo was as heavy as the lumbering folds of his own drapery; and so insipid are his large pictures, that it is a question whether they did not generate in Europe a contempt for large scripture subjects, which has lasted ever since. However, imbecility had not done spawning; and in a faint struggle for offspring against nature, out came Pompio Battone, and Raphael Mengs. To complete the farce, academies began to be founded in France and in the rest of Europe; and Pompeo Battoni, and Raphael Mengs may be looked upon as a very fair sample of what academies can produce, have produced, and will probably produce to the end of time. Mengs was every thing but a man of genius. He was a bad painter and a deep critic; and his predicting that we had not the works which the ancients esteemed the most, was verified, in a most astonishing manner, by the discovery of the Elgin marbles. The prediction does honour to the sagacity of Mengs. Thus end two great schools of form, conception, expression and composition; the Florentine and the Roman. But of these the Roman was unquestionably the greater.

Venetian school.

We now come to the Venetian, a great school of colour, light and shadow, impasto, and execution, completing the imitation of reality; and in summing up the character of Italian and Greek art, we shall see that these components of imitation, each of which characterised an Italian school, were combined in all schools, as a necessary requisite in the perfection of Grecian imitation.

The most ancient work of Venetian art known, is in Verona, in the cellar of a monastery, (Santi Nazario a Celso). It is inaccessible to the public, but can be seen in the woodcuts of Dionisi. In the part which formed the oratorio of the faithful, has been painted the mystery of redemption; it is a

work of 1070, when the Doge Silvo invited Grecian mosaic painters to adorn St. Mark; men who though rude in art, could nevertheless paint. Thus commenced the art in Venice, whither, after Constantinople was taken by the Venetians in 1204, Greek painters and sculptors, as well as orefici, flocked in crowds.

In the thirteenth century, painters had increased so much, that a company was formed, like the English constituent body to which Hogarth belonged, and laws and constitutions were made. Things were proceeding in this train when Giotto, returning from Avignon, painted at Verona and Padua. Nothing of his, however, is left in Verona; but at Padua the remains of his works are still quite fresh in fresco, and full of grace and vigour. Such was the early beginning of this great school, in which it will be seen that Greeks, as usual, had the first hand. Various names sprung up in this period, but the Bellinis are the most important. One of them was engaged by Mohammed II. and by his talents upheld the honour of the Venetian name; another was the master of Titian and Giorgione, two of the greatest names of the Venetian school.

Giorgione.

Giorgione was a great genius; and his execution was entirely above vulgar prejudices. He saw and seized the leading points of leading objects, and hit them with a touch and an impasto, of which he had no previous example even in Leonardo. His breadth and tone were beautiful; and he first opened the eyes of Titian to the superior value of breadth and touch, as compared with over-wrought labour and smooth finish. Giorgione died in the vigour of his life, to the great loss of the art; for there is no knowing how much farther he would have carried his principles, or how successfully he would have disputed the crown with Titian. Lord Carlisle has a small picture by this eminent man, of a youth buckling on the armour of a knight, which is exquisite in tone, brilliancy, depth, and feeling; and had he not been cut off by the plague, there is no knowing how far he might have gone. He certainly first opened Titian's eyes to the value of breadth, and that comprehension of mind required to seize the leading characteristics of objects by a touch, leaving the atmosphere to finish at a given distance. After his death, Titian was without a rival. This great painter began, of course, like all Venetians, to paint directly from nature, without having previously dissected or drawn; nor was he sensible of this error of the Venetian school, till coming to Rome and seeing the works of Michel Angelo, Raffaelle, and the antique, he, like a great genius, set about remedying his deficiency; and the perfection of this union of form and colour is seen in his greatest work, Pietro Martyre, any attempt to move which from Venice, the Venetian senate decreed should be punished with death. This picture occupied him eight years; and eight years were well spent in such a production. The terrific gasping energy of the assassin, who has cut down the monk; the awful prostration of the monk, wounded, and imploring heaven; the flight of his companion, striding away in terror, with his dark mantle against a blue sky; the towering and waving trees, the entrance, as it were, to a dreadful forest; the embrowned tone of the whole picture, with its dark azure and evening sky, the distant mountains below, and splendid glory above, contrasting with the gloomy horrors of the murder; its perfect, though not refined drawing, its sublime expression, dreadful light and shadow, and exquisite colour; all united, render this the most perfect picture in Italian art. Why does not one perfect work entitle a man to rank as highly as a series of imperfect works, like the Capella Sistina? The answer is, because there is greater range of capacity shewn in a series of conceptions to illustrate a theory, than in the completion of one work alone, although all the component parts may be perfect; and Raffaelle, and Michel Angelo, will ever rank higher than Titian, as Polygnotus will rank higher than Protogenes or Apelles. Prolific thinking, is surely of more value than intensity of imitation, though intensity of imitation must be added to realize the idea of a perfect painter.

Titian.

Titian began in the style of his master Bellini, with the most minute finish; a capital basis for future practice, if a man have comprehension to know when to leave it, as Titian did. To shew the young artist that it is never too late to improve, let him compare the Bacchus and Ariadne in our National Gallery, when he could not draw finely, with the Pietro Martyre when he could. In modern art, he was the only painter who hit the characteristic of flesh. Every great painter's flesh is paint; Titian's had real circulation of blood under the skin. On comparing the Ganymede, in our National Gallery, fine as it came from Titian's pencil, with the Theodosius by Vandyke, which is close to it, as fine a specimen of Vandyke's fire of brush as can be seen, the heavy leathern look of Vandyke's colour excited astonishment. In the flesh of Ganymede, colour, oil, brush, and canvas, were all entirely forgotten; it quivered, it moved with the action of the limbs. In Vandyke, the materials of art are uppermost; you think of them, you wonder at the touch, you forget the subject, the expressions as it were scenting of the painter's room and the easel. And so you do with all the Flemings, but never with Titian. Though we have fine Titians in England, the Diana being at Lord Egerton's, and a head at the Duke of Sutherland's; yet it must be confessed, that the Louvre possesses Titians more perfect, especially the entombing of Christ. In Josephine's collection at Malmaison, there were a Venus and Cupid, as perfect as our Ganymede, and not injured by *restoring*, the fatal propensity of the French. In Titian whenever you see the blues sober and in harmony, the picture is uninjured; whenever you see them harsh and too brilliant, they have been rubbed, and the last tone has been taken off.

In colour, he was never equalled; in execution of the brush, he was quite perfect; and in character and expression of portrait he was like Reynolds elevated and sublime; but the dullness which portrait, if perpetually practised, engenders in the capacity to idealise and elevate, rendered his conception of poetical characters defective. Nothing can exceed his Aretino, his senators, and his popes; nothing can exceed Sir Joshua's Lord Heathfield and Mrs. Siddons; but nothing can be meaner than some of Titian's attempts, like Raffaelle, at high poetical expression, except some of Reynolds' heads in the Beaufort. The nerve and beauty of the colour in Diana and Acteon are so touching, that one can almost fancy one hears the water ripple and the leaves wave. Glazing was the great feature in his tone, as it was in that of Apelles; and there is no perfect colour without it.

The first requisite in fine colour is the ground or preparation spread over the canvas to receive the colours. It is either of a nature to absorb the oil, or to resist the absorption. If it resist the absorption of the oil out of the colour put on it, it is an oil-ground; if it absorb the oil, it is a water-ground. And it has long been an interesting question, whether the Venetians used an oil-ground or an absorbent ground; whether, like the Greeks, they worked in tempera, and varnished out, or whether they judiciously mingled both oil and tempera together. One would think that Vasari, living as he did with all the great painters, could not be ignorant of their various methods of practice. In 1567 or 1568, he called on Titian, saw him, stayed with him, was in his painting-room, and must have talked on art, and perhaps dined or supped with him.[1] But Vasari distinctly says, in a sort of recipe-introduction to his lives (edition 1568) "that the ground on wood was *gesso*, plaster of Paris; that

[1] All the great painters seemed to prefer *supper*. In Tichozzi, Titian seems to have been a sociable man, and there are extracts from Titian's and Aretino's letters, alluding to pheasants, and presents of birds for the *next supper*.

then they mixed three colours, white, yellow, and amber, and spread them equally over the white ground; and that after tracing their cartoons, they painted their pictures." A more abominable ground never was mixed; to those who have an organ of colour it is an absolute emetic; and though it might have been Vasari's and the Florentines' ground, it never could have been endured by the eye of a Venetian. "This was the method," says Vasari, "for pictures on wood; but when canvas became the fashion, gesso being likely to crack in ceiling, they made a ground of flour (*farina*), white lead, and nut-oil, after the canvas had been smoothed by size."[1]

Now when this was published, Titian, Tintoretto, and Paolo Veronese were alive and all at work; and it is but common sense to conclude, that had it been false, they would have contradicted it. Vasari concludes with saying, "So are painted all the great works in St. Mark's Place, Venice." In that place was the Miracle of the Slave, by Tintoretto, afterwards seen by every body in the Louvre. Lanzi says, that the Venetians preferred canvas, but that at first they painted in tempera, and then came oil-painting, which the Venetians first adopted. On the arrival of the Bacchus and Ariadne in England, a little bit chipped off at the corner showed the ground underneath to be of the purest white. Now, if a white ground is absorbent, it sucks the oil out of the oil colours, and becomes the colour of oil. Sir Humphry Davy said to the author of this article in 1823, that in process of time oils become varnishes; and it is not impossible that the white ground of Titian may have been absorbent, and though it had sucked out the oil in the course of three hundred years, it may have recovered its original whiteness. The author's experience extends only to thirty years, and in that period an absorbent ground which sucked out oil has never recovered its whiteness.

But, if the Venetians painted first in tempera upon the white ground, and finished in oil, the tempera intervening between the last painting and the ground would preserve the ground white; and as Titian's method of proceeding was gradual and progressive in successive layers, like that of Protogenes, so that each layer became a help to the succeeding one, there is no reason to doubt that tempera might have been the first impasto. In parts of the Pietro Martyre, there certainly was the crude look of tempera preparation, softened by a glaze, especially about the projecting leg of the assassin. That the basis of Venetian pictures was a white ground, there can be no doubt; like the intonacos of Apelles, and the plaster-grounds of the painted mummy-coffins of Egypt. Tintoretto and Bassano used dark grounds to save trouble; but they are ruinous. They come through the thin half-tints of the picture, and render it distinct masses of dark and light, like most of the Lombard school. Many of the works of Paul Veronese, who painted one hundred years before, were in perfect preservation in the Louvre, whilst a number of the Lombard pictures were gone. The white ground was the "luce de dentro" of the Italians, "the light within." Upon this beautiful white ground they placed their colours purely and crudely, and then by spreading thin transparent tones, took down the rawness, without losing the force of the tint. This was the practice of the Greeks, and is also the present practice of the British school. When Cicognara, the president of the Venetian academy, was in England, he remarked to the author on the singular fact, that the British was the only school of colour left in the world, though our climate was the worst; and such was the state of Venice some years since, that an English consul could get nobody to paint the king's arms for him, and being the son of a painter, he was actually obliged to paint them himself.

As an example for the student, Titian is perfect. His execution never attracts by itself alone, but as the vehicle of the object it imitates. In colour he is never gaudy, never black in light and shadow, never forced or affected, and in drawing, latterly, grand. In composition he was not so perfect nor so fertile as Raffaelle; but in the imitation of flesh, no other artist in the world, except Apelles perhaps, could rival him. As a painter of portrait and landscape, no one has surpassed him. He did not grace his senatorial heads with the beauty of the backgrounds of Reynolds or Vandyke; but the absence of all gaiety behind the heads, perhaps added to the sublimity of their expression. It is curious to read in Boschini's little work, that young Palma, who had it from old Palma, a pupil of Titian, told him that Titian very often finished with his thumb. Palma distinctly says, that he has seen Titian put on with his thumb and fingers masses of colour which gave life to a picture.

In a word, neither of the great Italian schools showed the sense of the ancients. The Romans omitted colour and imitation from sheer accident; the Venetians drawing and form; and Reynolds, without going into the causes of these mutual deficiencies, laid it down as a principle, that colour and reality were incompatible with high art; whereas, when each school found out its deficiency, each endeavoured to correct its peculiar defect.

Tintoretto.

The giant of Titian's school was Tintoretto, who gave such early indications of self-will and genius, that Titian, mean and jealous, turned him out of the house. Raffaelle would not have done this; he did not turn out Julio Romano. But Tintoretto was not to be crushed by the bad passions of his envious master; and took it very properly as an evidence of his talent. And what did Titian get by his paltry meanness? Nothing but pity. Tintoretto, young as he was, immediately formed a plan of his own, for combining the drawing of Michel Angelo with the colour of Titian. He devoted the day to the one, and many parts of many nights, and often whole ones, to the other. In a few years, the result was the Miracle of the Slave and the Crucifixion. Although the execution of Tintoretto looked daring and impudent by the side of the modest, senatorial dignity of Titian, yet there was a grand, defined dash about it. The original sketch of the Miracle of the Slave, formerly in the possession of Rogers the poet, is a very fine thing. Everybody speaks of the Crucifixion as a wonderful instance of power. But in colour it is lurid and awful; in expression, character, and delicacy of feeling, discordant and offensive. His pictures seem to be a mass of fore-shortenings, affected twistings, dashing darks, and splashing lights, with a hundred horse-power of execution; bearded heads, Venetian armour, silks, satins, angels, horses, architecture, dogs, water, and brawny-armed and butcher-legged gondoliers, without pathos, passion, or refinement. He used to put little models in boxes, and light them in different holes, for effect. Like all Italians, he was accustomed to model and hang up his models by threads for fore-shortening. His style of form was a mixture of the pulpiness of the Venetian, and the long, anotomical, bony look of the Florentine school. He cannot be depended upon for correctness of proportions, but he was a grand and daring genius; and his conduct, when oppressed by Titian, should ever be held up as an example for the aspiring youth, when trodden upon by his elders.

Paul Veronese.

Whilst Tintoretto was astonishing the Venetians by his daring, which made even Titian tremble, Paul Veronese, the other great contemporary, was mildly pursuing his azure and beautiful course. Of a nature the reverse of Tintoretto, and not equal to him in sublimity or terror of conception, he yet gave equal evidence of being run away with by his brush. Ceilings, canvas, halls, walls, and palaces, were so many proofs of his power. His greatest work is at Paris. It is the Marriage of Cana, a wonderful instance of executive power;

[1] This is Vasari's account, pp. 51, 52, 53, Firenze, volume i. 1568.

but here all story, sentiment, and pathos, are buried in the noise, bustle, eating, drinking, and fiddling of a Venetian city feast. Paul Veronese was certainly the most corrupt painter of the time.

Cannaletti, &c.

After these great men, the art began to decay; and Paul Veronese and Tintoretto gave symptoms of a conventional mode, which, when taken up by inferior men, hastened its ruin. Down to the present age, with the exception of two or three mannerists, no name occurs worthy of eminence or selection Cannaletti was a genius in his way. Sebastian Ricci, and Marco Ricci, were much employed in England to disfigure ceilings and palaces by wholesale, with gods and goddesses. in subjects allegorical, poetical, mythological, and nonsensical, to understand which it required pages of explanation, and to see which a nine-feet telescope by Dolland. Montague, Burlington, and Bulstrode houses, are signs of the infatuation of the English nobility at that time; an infatuation, however, which shewed a disposition to employ art as it had been employed in Italy, and if the genius had been equal to the opportunity, the result would have been different.

Lombard and Parman school.

The next school of any importance is the Lombard school, which comprehends the Mantuan, the Modenese, the Cremonese, and the Milanese. Andrea Mantegna is the hero of the Mantuan school, and Vasari says, that his master-pieces are the tempera designs which we have at Hampton Court. They are fine things; Rubens used them; and they are a mine of costume, though the forms have too much the look of the model. Julio Romano's great work is at Mantua, yet he must be considered as a Roman. The works of Mantegna were, as Lanzi says, the greatest effort of the last style before Leonardo da Vinci introduced a new one, which overturned the Gothic. After Julio Romano, the art decayed, and then of course came the old story, "Una accademia per avvivarla." This academy has been splendidly kept up by Austria, and, as usual, has not produced a single man of great genius in three hundred years.

Corregio.

Contiguous to the Modenese school is the Parman; and now we come to the most unaccountable and delightful of all painters, Corregio. When it had been determined to ornament the great cupola of St. John, Corregio, though then a young man, was selected to paint it; and, like Raffaelle, his genius expanded with the opportunity. After Raffaelle, Titian, Michel Angelo, Da Vinci, and Bartolomeo, who would have thought that another style, independent of either, and unlike any thing else in the world, could have burst out? But so it was. Of all the painters that ever lived in the world, there is no accounting for Corregio. Unlike Greeks, Romans, and Italians, out he came into the world, in colour, drawing, light and shadow, composition, expression, and form, like nature, and unlike every body else, who ever studied nature at all. Michel Angelo, Raffaelle, Titian, we can trace; we see upon whom they were grafted, when they budded and burst forth. But who is Corregio? Nobody is certain. One swears he was poor, another that he was well off; another says he died in consequence of a fever which he caught by carrying all his money in copper, the price of a picture; another protests it was no such thing. Mengs' account is the best; and Vasari's mostly without authority.

There is no certainty that his portrait is in existence; in fact there is as much dispute about it as there is about Shakespeare's; and here are his beautiful works, his Notte, his Catherine, his Christ in the Garden, his Magdalene, his Venus and Mercury, and his *Ecce Homo* in the National Gallery, the only head of Christ in the world. This head of Christ ought to be reverenced as the identification of the character, as much as the head of Jupiter by Phidias was in the Pagan world. There is no Christ's head by Raffaelle which at all approaches it, either in the Transfiguration or in any other work; and the head by Leonardo da Vinci in the gallery cannot be endured after it. Of all painters, he astonishes one the most. If any fault is to be found with him, his men have a touch too effeminate. His colour is exquisite; his light and shadow are enchanting, but his forms defective; his composition is simple and infantine; his expression unimpassioned, but sweetness itself; and when sorrow or suffering was to be represented, who ever did it more tenderly than Corregio? Let any man who doubts this, dwell for a moment on the gentle suffering, and the feminine yet manly beauty of the Christ above mentioned. It is the very Christ who commanded by submission; without weakness beautiful, without effeminacy tender; without taint the personification of love. His hands, his shoulders, his beard, his hair, belong to that divine being who vanquished sin, by yielding to torture. It does not seem painted, but as it were spread upon the canvas by an angel's breath. His men look as innocent as girls; his women as guileless as infants; and his infants as if they had just come from the skies.

In the cupola at Parma, the great wonder is the fore-shortening; and in the mouths of the vulgar this is technical perfection; whereas there is nothing more purely mechanical, nothing in fact you can so easily teach. One single smile of Corregio's angels, one touching look of Raffaelle's apostles, the sentiment of the Duke de Lorenzo by Michel Angelo, one crimson tone by Titian, are worth all the fore-shortening on earth. The greatest excellencies of Signorelli, Buonarotti, and Corregio, are said to be their fore-shortenings; whereas the greatest excellencies of Buonarotti and Corregio are not their fore-shortening at all.

In spite of the perfections of this wonderful man, he founded as it were the decay, "le commencement de la fin." His breadth in fresco produced Lanfranco, Cortona, and Giordano, who covered Italian palaces with the *sweeping* brush of our patent chimney-cleansers, beginning it in the morning, finishing it by the evening, standing on the floor, and disdaining a scaffold, previous study, or previous thinking; and others came who bedaubed the palaces of Europe with clouds like feather-beds, cornucopias and Jupiters, till one's brain aches in thinking of them.

Reynolds was immensely indebted to Corregio; for Rembrandt and Corregio are certainly the bases of his style. One of the most beautiful works in the Louvre was the Marriage of St. Catherine, which when once seen haunts us in after life in dreams. In a word, Corregio was an angel that passing this earth in its flight, drooped its wings and dropped upon it, to give us a foretaste of the smiles which welcome a happy spirit in a purer sphere.

Parmegiano.

Parmegiano is the next important name in this school, who grafted the grace of Corregio on the affectations of Michel Angelo. His greatest work is in our National Gallery; the Vision of St. Jerome. The Christ is a beautiful boy, but affected; the Virgin is Michel-Angelesque, having the *Glumdalclitch* look of his Brobdignagian women. St. John is finely drawn, but not unexceptionable; and the St. Jerome is sleeping in a position as if he had got into a cramp in the first part of the vision, and could not get out till it was over. It is raw in colour, skinned in construction, and spoils the composition altogether. His small pictures are beautiful but long in proportion. His fingers seem always to move to music; and his limbs to be conscious how gracefully they are disposed. He has often been a fatal example to the young. Nor is his Moses, whatever Gray may say of it, an instance of the sublime. The expression is mean, and the form overdone. Parmegiano died, like Raffaelle at the age of thirty-seven, when all that was expected of him had not been realised, and when, if he had lived longer, perhaps he would have done worse.

School of Bologna.

In 1570, the best Corregieschi were grown old or dead, and the school of Parma began to give way to that of Bologna, the truly great academical school. This was not an academy in the modern sense of the word; it was a school, and nothing but a school, without distinctions, and managed

by directors; and it is the only academy which has ever produced any genius. Dominichino, Guido, and other names of the second period, came between unrivalled excellence and approaching destruction, and stopped for a little time the decay of the art.

Of the Cremona school, there is no great name. In the Milanese school, Da Vinci seems the hero; he founded an academy which, according to Lanzi, was the first in Europe that reduced art to rules, the works of Leonardo being the canon. His great work is in the refectory. But fifty years afterwards Aramini says that it was spoiled; in 1642 Scannelli writes, that it was with difficulty made out; and Barry ultimately saw it destroyed by a *restorer*. When Eugene Beauharnois was viceroy of Italy, he drained the refectory and had it paved with tiles; and it is said in a report, that the colours began to revive. Da Vinci's academy having produced no talent, Maria Theresa founded another, which, though full of casts of every description, has nevertheless proved equally unsuccessful.

The Caracci and their pupils were the last crop of genius which Italy threw up, and though they were second-rate, they came of the breed of the great who were no more. The style of Michel Angelo seems to have taken early root in Bologna, perhaps from his executing in that place the statue of Julius II. Giotto, in the first instance, excited emulation by flying about Italy; but he seems to have scattered everywhere the seeds of art, and Tibaldi, after having studied in Rome, certainly founded this style at Bologna. The first school formed was by Bagna Cavallo, and Primaticcio. It failed in 1564; upon which Primaticcio went to France, and Tibaldi to Spain, and the art was of course neglected.

The Caracci succeeded them and were extraordinary men; but what would they have done if Raffaelle, Michel Angelo, Titian, and Corregio had never lived? They saw nature only by the help of their great predecessors. Whatever the Caracci did had the appearance of labour; whilst whatever was done by their great predecessors, had an air as if there was something that no labour could attain. Ludovico had more feeling than his brothers, and had the honour of being instructed by Tintoretto. They were the sons of a tailor, and founded an academy in their own house. Agostino principally engraved, and Annibale principally painted; but they each contributed instruction to the school in which were formed Dominichino, Guido, Lanfranco, Guercino, and Albano.

Guido, Guercino, and Albano.

The greatest genius of the school was Guido; but he was envied by the Caracci; and even in this school the vices of an academy began to appear. We did not find Raffaelle sowing discord amongst his pupils by putting one against the other. Albano was opposed to Guido. Dominichino was an eminent but heavy genius; and his communion of St. Jerome is a fine thing though dull. There was a vulgar grandeur about Guercino, and an insipidity about Albano. The great work of Annibale Caracci is the Farnese gallery, which is excellent in every thing, but nerve and genius. Say what you will about the Caracci, there is a want in their art, which affects the pen of him who is attempting to do them justice. They lived together, did not marry, and were ill paid and ill-tempered; like all old bachelors they were discontented, they did not know why, and fidgety, they did not know for what; they envied the talents they were desirous of bringing forward, called the art their "wife," and were never satisfied, living in a perpetual fret of teaching, and painting, and complaining. Annibale became dissipated and died early. It is an extraordinary feature in the moral character of the Italian artists, that the greater part did not marry, and hence came the cant "of the art being their wife," with the natural consequence, that girls who had been models generally ended by being mistresses.

The Caracci kept up this affectation, they said the art was their "cara sposa;" and to all the confusion of a bachelor's house, added the slang of a mere painter's habits. At the dinner-table, crayon and paper were always at hand to catch attitudes, actions, and expressions, and groups; as if expressions and attitudes could not have been remembered in the solitude of the study, and kept till wanted with just as much effect as this vulgar intrusion on the usages of society. A great artist is always a man of the world; an inferior one a man of the palette. Raffaelle, Titian, Angelo, Rubens, and Reynolds, would have passed a twelvemonth in any society without being discovered to be artists; but the Caracci would have talked of tone and touching during the first half-hour. A genteel woman, accidentally travelling in a coach with three artists who were *palette-men*, expressed afterwards her wonder and suspicion as to the state of their intellects. For after the usual dead silence, one of them said, with an air of vast profundity: "How finely the white sheet in the hedge carries off the colour in the sky." "And look at that old woman's cloak taking up the brick-wall," said another. "Yes," said the oldest of the set, "how finely it was done yesterday by a red night-cap in a pretty bit of Sir George." Johnson used to say, "Sir, we were reduced to talk of the weather." But even the weather is preferable to this detestable affectation. Though the deepest principle of the ancients was the preservation of beauty in everything, they never sacrificed beauty to expression, but always combined the two; whereas Guido, by an eternal repetition of the expression of the Niobe in Christs and Virgins rendered the preservation of beauty at such an expense insipid. The beauty of the Helen and Paris was truly exquisite; but hundreds of Herodias's daughters with St. John's heads, "have a look," as Lord Byron says, "of bread and butter." His grace was the grace of theatres; his pencil light, airy, and beautiful, though rather careless than masterly. Dominichino, on the other hand, obedient, slow, and timid, imitated everybody and fell short of all. But Guercino was the most original of the school; his finest manner is his candlelight manner, yet still there is a vulgarity in his forms.

None of the Caracci or their school, had they been born at an earlier period, would have advanced the art one iota beyond their predecessors, so entirely dependent were they upon the great who had gone before. "Such was the state of art," says Fuseli, "when the spirit of machinery destroyed what was yet left of meaning;" when contrast and grouping meant composition and thinking, and a mass of rapid, thoughtless, empty, impudent frescos disgraced the walls, palaces, and churches of Italy. Pietro of Cortona and Luca Giordano are the heroes of this inundation of splashiness; and yet what artists they were! The decay which it announced, was the decay of the giant Italian fresco hand that still struggled to do its duty, whilst the head was fast approaching imbecility in thought. The meanest pupil of the meanest machinist would have swept the first-rate British artist that has ever yet existed into the earth, with his tiptoes and exhibition-glare.

Decline of Italian art.

Thus, with the Caracci and their school, ended the greatness of Italian art; nor has there been one single painter of such genius since, from Andrea Sacchi to Cammucini the present hero of the Romans. Rubens, Vandyke, and Rembrandt turned it into a new channel in Flanders; Velasquez and Murillo kept it alive in Spain; Teniers, Ostade, and Jan Steen preserved it from extinction in Holland; the Poussins, Claude, and Salvator, meanwhile revived it in Italy; whilst the old Gothic masters in Germany, with their colour, and most of them with great invention but in bad taste, were an absolute dung-hill of diamonds and pearls, which everybody has considered himself as having a right to plunder, not even excepting Raffaelle himself. Whilst the art was sunk to the lowest depths in Europe, Reynolds in England broke forth with a brilliancy of colour which

Painting. has rendered it no longer a hopeless attempt to rival the gorgeousness of Venetian splendour. If ever there was a refutation of Reynolds' own theory, that "genius was the child of circumstances," he was a living one; in spite of all circumstances, in spite of the utter want of all education as a painter, in spite of all the apathy of the nation, and the extinction of art in Europe, out he came with a vigour and beauty which have ever since defied rivalship in portrait and children.

German school. The Germans are an extraordinary nation, but always more or less under the influence of a wrong taste. Their early painters are full of thought; and as a proof of what Raffaelle's estimation of them must have been, he adopted almost to the letter, in his famous Spasimo in Spain, Shoengaer's magnificent composition of Christ bearing the cross. The hand leaning on the stone, with the momentary action of the drapery, is in Shoengaer. The brute pulling Christ, in an old German dress, Raffaelle has taken and improved; and he has also placed the Marys in the fore-ground which Shoengaer placed in the back-ground; but the whole of the composition is Shoengaer's, though Raffaelle of course has added to it his own perfections.

Albert Dürer. Albert Dürer is considered as the greatest man of the German school; but there is nothing which he has ever done that can compete, in expression and composition, with this fine production of Shoengaer's. Fuseli says, "Albert Dürer was a man of great ingenuity, but not of genius. His proportions of the human figure are on a comprehensive principle founded on nature, and the result of deep thinking." He had sometimes a glimpse of the sublime, but it was only a glimpse. The expanded agony of Christ on the Mount of Olives, and the mystic conception of his figure of Melancholy, are thoughts of sublimity, though the expression of the latter is weakened by the rubbish he has thrown about her. His Knight, attended by Death and the Fiend, is more capricious than terrible; and his Adam and Eve are two common models shut up in a rocky dungeon. "If he approached genius in any part of his art, it was in colour; his colour went beyond his age, and as far excelled in truth, and breadth, and handling, the oil colour of Raffaelle, as Raffaelle excelled him in every other quality. I speak of his easel-pictures; his drapery is broad though much too angular, and rather snapt than folded. Albert is called the father of the German school, though he neither reared scholars nor was imitated by the German artists of his or the succeeding century. That the exportation of his works to Italy should have effected a temporary change in the principles of some Tuscans who had studied Michel Angelo, as Andrea del Sarto, and Jacopo da Pontorino, is a fact which proves that minds as well as bodies may be at certain times subject to epidemic influences."

Flemish school. Von Leyden. Lucas von Leyden was the Dutch caricature of Albert Dürer; and ere long the style of Michel Angelo was adopted in the same way as by Pelegrino Tibaldi, and being spread by the graver of Giorgio Mantuano, provoked those caravans of German, Dutch, and Flemish students, who, on their return from Italy, introduced at the courts of Prague and Munich, in Flanders and the Netherlands, that preposterous manner, that bloated excrescence of swampy brains, which in the form of man left nothing human, distorted action and gesture with insane affectation, and dressed the gewgaws of children in colossal shapes, in the style of Golzius and Spranger. But though content to feed upon the husks of Tuscan design, they imbibed the colour of Venice, and spread the elements of that excellence which distinguished the succeeding schools of Flanders and of Holland. At this moment out blazed upon the world that giant of execution and brute violence of brush, and brilliant colour, and daring composition, Rubens; and another mysterious and extraordinary being, Rembrandt, who seemed born to confound all theory but that of innate genius, confirmed it for ever. Rubens gloried in the splendour of the rainbow, whilst Rembrandt enjoyed only the poetry and solemnity of twilight; when the evening star glittered, and the sun was down, then was the hour of his inspiration.

Rubens. The scholar of Otho Venius, Rubens, imbibed from his master an emblematical taste; he spent eight years in Italy, hurried back at the death of his mother, and painted that wonder of art the Elevation of the Cross, before he was thirty. It is the perfection of a fearless hand and daring brush, conscious of its principle; and though the sweep of Michel Angelo's contours, applied to butchers' backs and coal-heavers' legs, rather increased their vulgarity than added to their refinement, yet the dashing power of that astonishing picture, in spite of its Flemish, pallid, and ugly wretches for women, renders it the bloom of his powers. Rubens was a man of such general knowledge, that the Marquis of Spinosa said, that painting was his least qualification. He was ambassador to Spain and England, and adorned the banqueting ceiling at Whitehall, the centre portion forming an amazing picture. Educated classically, he carried classical feeling into every thing but his art; and after spouting Virgil with enthusiasm, he turned to his canvas and painted a Flemish butcher with bandy legs (if he happened to have such) for Æneas. How extraordinary it is that, relishing as he did, Homer, Virgil, and Livy, he should give Dutch Helens, Flemish Junos, and German Diomeds, for classic art. His greatest work is the Luxembourg Gallery; and for once he hit a sweet female expression in the mother of Mary de' Medicis, after accouchment. One of his finest pieces, the Rape of Proserpine, is at Blenheim, where the Arethusa, as a water nymph, is putting up her hand, with her back towards you. That a man who could occasionally paint with such delicacy, should so often disgust us with his flabby vulgarity, is not to be accounted for. He painted portrait finely, landscape sweetly, and animals with great power, except the lion, whose straight shaggy mane he always curled like the ancients, and lost its noble look. He was a great man, and painted wherever he went. He was diligent and religious; he rose at four, heard mass, and went to his painting-room, where, with little intermission, he painted till five; he then rode, and returned to his friends, many of them the most celebrated men of the day, who were assembled to meet him at supper; at eleven he retired, and again proceeded to work at day-break. It is interesting to contrast this virtuous course of so great a man, with the vulgar infidelity which alone distinguishes the most incompetent in the art; and it is impossible not to conclude, that those whom God has most endowed with gifts, are the most sensible of their own imperfections. Rubens was thrice married, and educated his children highly; one of them wrote a very learned work, *De lato Clavo*, which shews research and learning.

Nowhere did Rubens shine so effectually as in the Louvre. In all the world, perhaps, there never was such a splendid opportunity for studying to perfection the principles of the great men in the art, as was afforded in the Louvre in its full glory; and injurious as the formation of that collection had proved to the cities of Italy, yet Napoleon gave a dignity and an importance to the art, which it has not since lost, by making the productions of its great men subjects of treaty, and receiving them as equivalent to territory or treasure. There you rushed from the Romans to the Venetians, from the Flemings to the Spaniards, from Titian to Raffaelle, from Rembrandt to Rubens, and settled principles in half an hour, which it took others months, perhaps years, to accomplish. It cannot be denied, that in force of effect, Rubens bore down all opposition, from his breadth, brightness, and depth; and let every painter be assured, that if he keep these three qualities of effect, the leading qualities in the imitation of nature, he will defy rivalship in the contest of exhibition.

Rembrandt, with all his magic, painting on too confined a principle, lost in power, and looked spotty and individual. Paul Veronese and Tintoretto had not that solidity, which is the characteristic of Rubens; Titian seemed above contest, and relying on his native majesty of colour, exhibited a senatorial repose, which gave to Rubens a look almost of impertinence; but still you could not keep your eyes off the seducer, and even if you turned your back, you kept peeping over your shoulder. Here all peculiarity suffered. The silvery beauty of Guido looked grey; the correctness of Raffaelle looked hard; Rembrandt failed most by the brightness of Rubens, the magic of Corregio, or the sunny splendour of Titian; and after wandering about for days, you decided that *he* suffered most who had most peculiarity. With all his grossness, want of beauty, and artificial style, Rubens' brightness and breadth carried the day, as far as arresting the eye, and forcing you to look at him, hate as you might his vulgarity, and his Flemish women, and his Flanders breed of horses.

Rembrandt

Rembrandt van Rhyn, was next to Rubens, in point of art, and more than equal to him in originality. Whether in portrait, landscape, or historical pictures large and small, he was like nobody; as wonderful as any, and sometimes superior to all. His bistre-drawings are exquisite, his etchings unrivalled; his colour, light and shadow, and surface, solemn, deep, and without example; but in the naked form, male or female, he was an Esquimaux. His notions of the delicate form of women, would have frightened an Arctic bear. Let the reader fancy a Billingsgate fish-woman, descending to a bath at a moment's notice, with hideous feet, large knees and bony legs, a black eye, and a dirty night-cap,—and he will have a perfect idea of Rembrandt's conception of female beauty. Though his historical pictures are often remarkable for pathos and expression, his characters are sometimes absolutely ridiculous. His Abrahams are Dutch old clothesmen; and yet his Jacob's Dream is sublime beyond expression. Whatever he painted, he enriched; his surface was a mass of genius, and his colour a rainbow, darkened by the gloom of twilight. In portrait, sometimes, his dignity was equal to Titian; but the characters he painted were inferior.

These two wonderful men, each a perfect contrast to the other, revived art; Rubens on the principles of the Venetians, and Rembrandt in defiance of all principles. But the latter sacrificed too much to a peculiarity, and he was punished for it in the Louvre by the side of others.

Vandyke, &c.

Rubens produced Vandyke, Snyders, and Jordaens, and a whole host of pupils. Vandyke had more elegance, but not so much imagination; Jordaens more vulgarity, with equal power. Snyders was a mere animal painter, and he carried the touch necessary to execute the hairy skin of an animal, into every thing he did. Vandyke by his splendid portraits, certainly generated a love of art in England, which has never left us, after the destruction of historical painting at the Reformation.

Teniers, &c.

Rembrandt had pupils, who were by no means equal to himself. David Teniers the elder was a pupil of Rubens. These two extraordinary men were certainly the founders of the Dutch school; and the great principles of their works were carried by David Teniers the younger, Jan Steen, Ostade, and Cuyp, into smaller and more delicate productions. A man of the highest ambition and noblest views in art can study with the greatest benefit the dead fish and bunches of turnips, servant girls and drunken boors, for beauty of handling and effects in art. He who looks down on the excellencies of the Dutch school, does so from a narrowness of understanding, and not an enlargement of views; and if an historical painter can see nothing to learn in their little beautiful works, he will not learn much from the greater productions of Titian.

Spanish school.

Directly after the Flemish comes the Spanish school, which, not so vulgar as the former, was equally unideal. The Spaniards painted the people about them for all sorts of subjects and all sorts of characters; and they are only more refined than the Flemings because the Spaniards are a more cultivated people. The long possession of the Moors prevented the Spaniards from advancing as soon as Italy. The great schools in Spain have been those of Madrid, Seville, and Valencia. In 1446 Antonio Rincon abandoned the Gothic of the European artists; in 1475 Gallegos was so like Albert Dürer, that he is suspected to have been a pupil; in the sixteenth century riches flowed in, patronage was liberal, and, what is most important of all, genius existed in Spain. Becerra de Baeza, pupil of Michel Angelo, painted in fresco, at Madrid, Salamanca, and Valladolid; and in the Trinità del Monte in Rome, there is also a picture of his. Various painters follow of course in all the schools, till the coming of the real hero of Spanish art.

Velasquez.

Velasquez was born at Seville in 1599. He became a pupil of Herrera, and left Seville in 1622, to seek his fortune in the metropolis; where he succeeded so completely as a portrait painter, that he got to court, and having become acquainted with Rubens, often visited his painting-room. Rubens must have been of the greatest use to him. Velasquez then visited Italy, but could not bear the Roman school after the Venetian. In masterly execution and life he surpassed Rubens and Vandyke. Of all the great painters, he seems to have despised the most the vulgar appetite for what is called *finish*, that is, polished smoothness. Every touch from Velasquez is a *thought* calculated to express the leading points of the *thing* intended to convey it. Masterly beyond description, and delightful beyond belief, he conveyed the impressions of life as exquisitely as if his imitation breathed. But so utterly decayed is the present Spanish school, with its pompous academy, that Spaniards when asked how they can reconcile their hideous polish with the freedom of Velasquez, have answered that *Velasquez was always in a hurry.*

Murillo.

After Velasquez ranks Murillo, a man of a tenderer genius, but equally alive to life. He has the surface of Corregio and colour peculiarly his own; and he was what the Italians call a *Naturaliste*, indeed, the whole school was of that species. Like Rembrandt and Rubens, the heroes of history are always the countrymen of the Spanish painter. The Prodigal Son is one of the finest works in the Duke of Sutherland's collection; it is beautiful in execution, light and shadow, and colour, but Spanish in character and expression. They never got beyond their model or their country; and this may in a great measure be owing to their masters having been Venetians, though Tibaldi and Torrigiano had visited Spain. Murillo was an exquisite painter, and if he had been soundly educated like the Greeks, would have been as refined in character and form as he is now in colour and handling. He first got an insight into painting from Moya, a pupil of Vandyke. Having sold his pictures to hawkers for what they would bring, he saved money and went to Madrid, and, with the frankness of genius, at once introduced himself to Velasquez, who received him like another Raffaelle. After three years of continued kindness, he returned to Seville, founded an Academy, and for his great work of St. Antony at Padua, he received ten thousand reals. It is said that he covered more canvas than any body else; but after the acres of Rubens in the Louvre, that assertion is questionable. Velasquez and Murillo, of course, came like the rest, *before* academies. One now exists in Madrid, and no genius has appeared since its institution. It is quite ridiculous to see the same results all over the world; and it is still more ridiculous, to find the kings of Europe still continuing to found and embellish these useless establishments.

French school.

In France, throughout all the middle ages, the art of design was never extinct, either in mosaic, glass, tapestry, fresco, miniature, or tempera. Though the learned author of the "Discours Historique" says, that the French were the first who presumed to personify the Almighty in the form of

Painting.

man; yet nothing worth remembering occurred till the death of Leonardo, in the arms of Francis I. in 1518, and the employment of Primaticcio, Rosso, and Nicolo del Abbate. Jean Cousin in 1462, and Vouet in 1582, were the first French painters of any importance in this latter period. Simon Vouet, the younger, was the master of Le Sueur, Le Brun, Mignard, and Dufresnoy; he lived in 1600, and the best period of French art was from that time until 1665, the beginning of the reign of Louis XIV. They, as usual, founded an academy, ten years before Poussin's death; and Coypel, Jouvenet, and Rigaud, were the produce of the institution; whilst Poussin, Le Sueur, and Le Brun, had flourished and obtained their reputation before it was founded. Van Loo and Boucher succeeded Jouvenet and Rigaud, and gave additional evidence of the utter incompetence of the academic system. About 1770, flourished Greuze, who began to evince a better taste, and was persecuted by the Royal Academy for his independence, till the Revolution of 1790 put an end for the time to all imposture. Down went the Royal Academy in an instant; and all the conventional distinctions in art, which are generally the cloak of imbecility, were fluttered off in the whirlwind. The people, long prevented from seeing fine works in the great galleries, now broke into these galleries with brutal exultation. Bloody and dreadful as were the consequences of the first burst of the French Revolution, one of its most beneficial effects consisted in throwing open all matters of art and science to the people. Naigeon, the conservator of the Luxembourg, said, in 1814, that nothing was opened to the people before the Revolution; and we ourselves in England are now enjoying our Museums, entirely in consequence of the effect produced upon Mr. Fox and the English, who visited Paris in the year 1802, and who were astonished at the noble frankness with which the Louvre was exposed.

The academy being swallowed up in the whirlpool of political revolution, the Institute supplied its place. Napoleon, on becoming first consul, sent immediately for David, who had been a furious republican during "le temps de la terreur;" a man of great talent, but of abominable taste. Napoleon made him his court-painter, and gave such preponderance to his influence, that the detestable style of David became everywhere but in England the style of European art. Gros, Prudhom, Guérin, deviated from the rigidity of David's style. Prudhom was a man of genius. Hideous as was the style of David, in fact painted Roman sculpture, it had some foundation in reason. This was, if possible, to bring the French back to classical art, after the flutter of Boucher, and the pomposity of Coypel; but, like all reformers, he went to excess.

The materials for assisting them are so deficient, that the greatest artists have arrived at any thing like an imitation of nature only by the greatest science and skill. It is much easier to paint a button and a chair, than a human face; therefore the great artists dwelt upon the face with all their dexterity, and touched off the button and chair with less anxiety and care. The French used to say, that *theirs* was the system of the ancient Greeks, and that it was *our* prejudice to disapprove of it. But before we have done, we shall show that it was not the system of the ancient Greeks; and as we pay all due deference to the Italians, Flemings, Dutch, Spaniards, and Greeks, and to their own Poussin and Claude, they have no right to accuse us of prejudice because we disapprove of David. We do not deny David's talent, because it must have required talent to mislead the continent of Europe. In art David's expression was taken from the theatre, and his actions were borrowed from the opera house; his forms were Roman and not Grecian, and his colour was hideous enough to produce ophthalmia. If he and his pictures, with all he ever designed, and all he ever invented, had not appeared in the world, or having appeared, had been utterly rooted out of it, the atmosphere would be purer. He is a plague-spot, a whitened leprosy in painting, that haunts the imagination with disgust. This he had the impudence to say of Rubens. But since the peace, and from the connection with England, a better school of colour has sprung up in France; and La Roche gives evidence of having in some degree got rid of the furniture look of David, though it still poisons a French pencil.

Painting.

Horace Vernet is a distinguished name; indeed, he may be called the first light-infantry grenadier of European art. He paints a head in five minutes, a whole imperial family in ten minutes, and an historical picture in twenty; and he paints all three with talent and skill. Though the French are not yet *sound* in art, they are the best educated artists in Europe; and if the English would combine their own colour with the careful habits of French early study, and if each school could supply the deficiencies of the other, they would make out a very good school between them.

In thus suffering ourselves to be led away to the modern state of the French school, we have omitted to do justice to the great men of former times; Poussin, Sebastian, Bourdon, and Le Sueur. Poussin is the hero of French art. His Death of Germanicus is very fine, as a specimen of history; and his Polyphemus sitting on the top of a mountain, and playing his pipe, with his back towards you, is a pure specimen of the poetic. He studied the ancient Romans so much, that he became Roman in his faces, drapery, and figures; and in his naked forms, the common model is too apparent. His finest works are in England; but though distinguished for expression, there is always an antique heartlessness, as if copied from the masks of an ancient theatre.

Bourdon's Return of the Ark is a high proof of his conception; and Le Sueur's St. Bruno is pure in taste, but bad in colour. The Battles of Alexander by Le Brun show the latter to have been of the family of machinists. His colour is bronzed and disagreeable. Le Brun was a court-favourite, and his Greeks, as well as barbarians, have an air of the opera at Versailles. His composition is artificial; and he is not a fit example for youth. The only man who coloured with exquisite feeling was Watteau, whose touch and delicacy of tint may be studied with great profit by any artist.

In a word, it is extraordinary that the French as a nation, have never been right in art. Poussin was the only man who could have set them right, and they persecuted him so, that he settled in Rome. Claude Lorraine can hardly belong to them; and though Louis Philippe employed them by hundreds, nothing very eminent appears to have proceeded from such encouragement.

Progress of the Germans.

The Germans are taking higher ground than any other nation, and are making rapid advances, particularly at Munich. They have begun again fresco painting; and the liberality of their king has rendered Munich the most flourishing city in Europe for arts and artists; but as Canova said when he was in England, there is very little grand art left in the world. It is extraordinary to reflect on the little original thinking that is to be found. This was more apparent in the Louvre than any where else; and one could not help being amused at seeing the way in which Rubens, who, like Michel Angelo, is supposed to have never looked out of himself, had plundered the old Gothic painters; the Fall of the Damned, by an old German, being the complete basis of the same subject by Rubens.

When incessant demands are made on the genius of a favourite, every aid to thinking is grasped at and improved. Raffaelle did this; so did Rubens; and even Reynolds used to have portfolios brought him to look over at breakfast, and select what would help him, saying, "It will save me the trouble of thinking." This involves a very serious question in art. The utmost merit that can be allowed is that of *skilful adaptation*. "Nihil tetigit quod non ornavit" may be said of all these; and surely a good thought badly done is justifiable food for a superior mind to render it better.

Painting.

British school.

We come now to the British School, which, though the last founded in Europe, is inferior to none in variety of power. There is no doubt that the art[1] would have advanced in Britain side by side with the continental nations, if we had continued Catholics; in fact, we were doing so, when Wickliffe's opposition to the Catholic priests roused up the people to hate and detest every thing connected with their system. Painting of course came under this furious denunciation, and through successive ages went on till the period of the Reformation.

Historical notices of British art.

In Edward the Confessor's time, there were executed bas-reliefs as good as any thing done at that time in Europe, and by no means deficient in grace, though disproportioned, and unskilful in composition. In one of these there is a king in bed, and leaning upon his hand; which in an improved style might be made a fine thing. In Alfred's reign and before, York and Canterbury were adorned with pictures and tapestry; and in the tenth century, Ethelrida adorned Ely Cathedral with a series of historical pictures in memory of her famous husband Birthwood. As this is recorded, says Strutt, the practice must have existed before; and that it continued to exist and be the fashion down to the Edwards and Henrys, there is good evidence; for in the time of Henry III. mention is made of the immortal Master Walker's painting in Westminster, the no less renowned John Thornton of Coventry, painter there, and the east window of York.[2] In the reign of Henry VIII. there was a chartered society of painters; and in the seventeenth of Elizabeth it was moved in the House by Sir G. Moore, "that a bill to redress certain grievances in painting be let sleep, and be referred to the Lord Mayor, as it concerned a controversy between *painters and plaisterers;*" and Sir Stephen Jones stood up and desired that the Lord Mayor "might not be troubled, and *it seemed to go against the painters.*"

The painters who complained that the plaisterers used their colours, and took the bread out of their mouths, go on to say, that in the nineteenth of Edward IV., that is in 1480, there were orders issued "for the use of *oil* and *size,*" and that the "painters' only mixture was *oil* and *size,* which the plaisterers do now usurp and intrude upon." In their petition they observe with the greatest simplicity: "Workmanship and skill is the gift of God, and not one in ten proveth a workman, and that those who cannot attain excellence must live by the baser part of the science." They add that "painting on cloth is *decayed;* that this art is a curious art, and requireth a good eye, and a stedfast hand, which the infirmity of age decayeth, and then *painters go a-begging;*" and then they conclude the petition to the House by this remarkable passage: "*These walls thus curiously painted in former ages the images so perfectly done, do witness our forefathers' care in cherishing this art of painting.*" "This bill," said Sir Stephen Jones, "is very reasonable and fit to pass," and so it did.[3]

Painting.

The above extract, proves that in Elizabeth's reign the historical attempts were alluded to, *as belonging to former ages*, viz. from the tenth century downwards; that the House of Commons praised the wisdom of those times in cherishing painting; and that this wisdom the Reformation had obviously discarded.

In 1538, Henry issued an order against the use of pictures and statues to impose on the people; yet pictures are called "bokes for unlearned people." In 1542, in his letter to Cranmer, the king tries to restrain the destruction of pictures; but it was too late. In the reign of Edward VI. the Duke of Somerset fined and imprisoned all those who possessed pictures of religious subjects. To such excess had the fury of the people been excited, that the recorder of Salisbury, Mr. Henry Sherfield, was fined L.500, and imprisoned in the Fleet for not breaking a painted window in Salisbury Cathedral. Walpole says that one Bleese was employed at 2s. 6d. a-day to break windows at Croydon; and in Charles I.'s reign it was ordered,[4] that all pictures having the second person of the Trinity should be burnt, and that all pictures having the Virgin should share the same fate. Cromwell stopped this barbarity, and it was owing to the self-will of this extraordinary man that the Cartoons of Raffaelle were bought in for L.300, at the sale of Charles's effects.

Thus it is clear the art was stopped by the Reformation. In St. Stephen's Chapel, before the alterations made some years since, there were figures painted on the walls, as excellent as any figures in the Campo Santo, and perhaps executed about the same period. In Elizabeth's reign, as we have seen, historical art is referred to with sorrow in the House, as a thing past but which had existed; and in the same reign, says Hillier, "men induced by nature," to pursue high art, "have been made poorer, like the most *rare English drawers of story works.*" Now, Hillier would not have said this, if it had not been true that the drawers of *story works* were principally *natives*.

In Henry VII.'s time, Torrigiano, the same youth who had felled Michel Angelo to the ground in the gardens of Lorenzo and shattered his nose, was in England, and executed important works. In the time of Henry VIII., commissions for high art being over, Holbein devoted himself to court portrait-painting, though in the city he painted some large pictures. Rubens' and Vandyke's visit excited Dobson, a capital painter of a head; but although Oliver was distinguished as a miniature painter, and although there are designs at Oxford, by English painters, no one genius seemed to arise till after Lely and Kneller had succeeded Vandyke. Cooper was the first English painter employed in foreign courts as a miniature painter. Thornhill, a man of talent,

---

[1] It is a curious fact, that the art seems to have been in an advanced state in England, while it is doubtful whether there was a painter in Florence in 1236. In 1250 the authorities in Florence sent for some Greeks because there was no painter; yet at that period in England, and long before, historical painting seemed quite the fashion amongst the upper classes. All the king's rooms, as well as his chapel, were painted. In the 25th of Edward III. in the rolls of the Exchequer, 26th September 1351, there is a charge to "William of Padryngton, for making twenty angels to stand in the tabernacles by task-work, at 6s. 8d. for each image, L.6, 13s. 4d." In 1530, were begun the beautiful pictures and designs in St. Stephen's Chapel; and it is curious to see, in all the accounts, the continual allusions to oil-painting. The artists employed must certainly have been men of distinguished talent, who had the power of ordering inferior artists to assist them. The most celebrated of their number appears to have been Hugh de St. Alban's, who was appointed by the king as his principal painter. The following document, dated 18th March, 1350, contains his appointment. "The king to all and singular, the sheriffs, mayors, bailiffs, officers, and his other lieges, as well within liberties as without, to whom be greeting, Know ye, that we have appointed our beloved Hugh de St. Alban's, master of the painters assigned for the works to be executed in our chapel, at our palace at Westminster, to take and choose as many painters and other workmen as may be required for performing those works, in any places where it may seem expedient, either within liberties or without, in the counties of Kent, Middlesex, Essex, Surrey, and Sussex, and to cause those workmen to come to our palace aforesaid, there to remain in our service, at our wages, as long as it may be necessary. And therefore we command you to be counselling and assisting this Hugh, and completing what has been stated, as often and in such manner as the said Hugh may require." (See Britton's *West. Pal.* p. 170.) The illustrious Hugh seems to have been a designer; for in the books (25 Edward III. April 30), is the following entry, "to H. de St. Albans, ordering or *designing* the drawings for the painters, one day, 1s."

and a member of the House, forms the link between one race and another; and then sprung up Hogarth, Gainsborough, Wilson, West, and Barry. As usual, when Reynolds and Hogarth had for ever rescued Britain from all doubt as to her genius, without an academy of any description, a royal academy was founded to produce more genius, just as had been done all over Europe; and no man equal to Reynolds and Hogarth has since appeared. After the academy was founded at Milan by Leonardo, no genius like his appeared. After that of St. Luke was founded at Rome, Raffaelle and all being dead, no one came forth. After an academy had been founded at Parma, Corregio being gone, nobody appeared. After a national academy was founded at Venice, and royally endowed, genius fled. The same thing happened in Ferrara, Modena, Florence, and Naples; and also in France, Spain, and England. Need further evidence be sought of the uselessness of such institutions?

The Academy.

In 1711, there existed a school, of which Kneller was the head, whilst Vertue the engraver drew in it. After 1724, Sir James Thornhill opened a school in his own home Covent Garden, and so did the Duke of Richmond at Whitehall Privy Gardens. Sir James proposed to Lord Halifax to found a royal academy, but without success. At Sir James' death, the school was broken up, and the artists were again left without instruction; when, for the purpose of studying the living model, they hired a room in Greyhound Court, Arundel Street, and Michael Moses was the conductor of it. Here they were visited by Hogarth, who was so well pleased, that a union of the whole body took place, and they removed to Peter's Court, St. Martin's Lane. The number of members amounted to a hundred and forty-one, each paying an annual subscription. There was at the time a great deal of happy fellowship amongst the artists. Reynolds, who was a member, with Hogarth and others, adorned the Foundling Hospital; and the public were so interested, that the society thought they might venture on a charter, which was obtained, and there was established by law a government of twenty-four directors, annually elected, including the president, by the whole body and out of it. An united exhibition having begun (the constant source of irritation, for every man cannot have his works in the best places), squabbles arose; and the directors finding the benefit of being able to hang their own works and those of their friends in the best situations, intrigued to keep their places another year. This was foolishly granted; and every subsequent year finding themselves becoming a match for the constituency, they kept their places for eight years, in defiance of law; so that at last it was found that the men elected to preserve order and law, had been the grossest violators of both. With the feelings of independent freemen, the constituencies resolved to endure this no longer; when, to prevent collision, it was agreed to refer the point to the Attorney-General, De Grey, both parties pledging themselves to abide by his decision. De Grey gave it against the directors, and these honourable men then refused to keep their word. The constituency met, and violently expelled sixteen of them; but before resigning, these gentlemen met secretly, and fearing exposure, tore out and destroyed the minutes from the 19th November 1764, to the 11th March 1765, and from the 17th of June 1765, to the 21st of March 1766. They then went to the king, George III., whom they persuaded that the chartered body was republican; and that there was no hope unless a royal academy was founded, with the number of members and voters limited to forty. The king, without inquiry, foolishly yielded to their cunning suggestions, and founded an academy with forty members; the other eight directors resigned directly, and the whole twenty-four were made R.A's. Thus by this limited number were framed the present exclusive law and constitution, and all the obnoxious regulations passed, which had been checked by the sense of a constituency; and thus the art of England received a blow more fatal than at the Reformation. The weakness of the nation has been gratified to an excess by this interested assembly, to the ruin of their taste and judgment; high art has gone back, and is going back further every year, by the struggles of these men to keep up their monopoly, in defiance of the increasing intelligence of the people, which they fear, and which will yet be their utter destruction. In this affair Reynolds behaved with great meanness. He promised to stand by the constituency; yielded at the offer of a knighthood; was afterwards justly punished, by being compelled to resign; and foolishly complained of ingratitude which he had deserved.

In order that the state of art in Great Britain may be rightly understood, this authentic detail, taken from pamphlets published at the time, especially that of Sir Robert Strange,[1] has been thought necessary; and it will not appear tedious, if it be considered that, for the sake of the art of our own country, it is but just that particulars should be ascertained. The effect of the academy has been pernicious. Imitating the example, all the eminent provincial towns have established exhibitions instead of schools; and every year the annual exhibition in the metropolis is repeated in the provinces, with but little addition to that which proved unsaleable in the London show. Hogarth opposed such a conclusion, and from the beginning predicted its effect, which has happened to the very letter; and when Reynolds began to perceive the truth, he acknowledged his error, and said to Sir George Beaumont, that "a party was gaining ground which would ruin the art."[2] If the detail of every other academy in Europe could be thus laid open, the same intrigues, the same despotism, the same injustice, and the same want of principle would be found at the bottom; and Europe would no longer wonder that academies never have produced a Raffaelle.

Reynolds.

The honest and straight forward constituency being thus left as it were unprotected by the king, it was soon deserted by the nobility and the public, and shortly escaped notice altogether; though such a man as Hogarth had improved his knowledge by drawing in its schools. The literary splendour with which Reynolds was surrounded, gave a glory to the Academy which it has not yet lost; and the genius of Reynolds spread a halo around it, which the artists still fancy they see, though it vanished the moment he expired. Reynolds was really a great artist; gorgeous in tone and colour, unimpeachable in composition, deep in light and shadow, beautiful in character, and the purest painter of children and women that ever lived in the art, Greek or Italian. His ignorance belonged to the period; his beauties were entirely his own; and though he overrated Michel Angelo, and has done injury to taste, by his sincere conviction that he was right, yet had he lived to see the Theseus or Ilyssus, he would have been equally candid in saying he was in error. Lord Heathfield is a portrait that need not fear any work of Titian's for men, and Mrs. Parker, a tender, sweet picture of a woman, was never equalled in sentiment or delicacy by any work of the Venetian and Roman schools. Where were children ever so completely hit as in the Infant Academy? who surpassed the propriety of his back-grounds as well as their splendour? His eye, or rather his organ for colour, was exquisite; nor is there in the whole of his works a heated and offensive tint. He did not combine essential detail and breadth so beautifully as

[1] See Sir Robert Strange's pamphlet, and another published in the year 1771, by Dixwell, St. Martin's Lane, entitled "On the Conduct of the Royal Academicians," in the British Museum.

[2] This was told the author by Sir George; and has since been confirmed by his pamphlet, "Concise Vindication," &c. in British Museum.

Painting

Titian; but place one of his finest portraits by the side of any picture of Titian's, see them at the proper distance, and Reynolds would keep his station. Here, however, the praise must stop. Reynolds could have no more painted Pietro Martyre than he could have revived the martyr after he was dead. He was not so great a man as Titian, because he did not like him remedy his ignorance, when he found it out at a much earlier age. He was always talking of what he would do if he began the world again. Sir Joshua loved society; he was the deity of his coterie; he liked a glass of wine and a game at whist; and he never lost his temper because he was successful in the world, but the first time he was thwarted he got in a passion. Reynolds was a great genius in painting, but not a great man. He raised English art from the dust, and gave English artists an *aplomb* in society which they never had before, and he first reduced the art to something like system by his discourses; but not having moral courage to resist the formation of an academy, which *he* could have done by his influence and his genius, he compromised the art, and was indirectly the means of throwing it off its balance, which it will yet take half a century more to remedy, as Hogarth predicted.

Hogarth.

As an inventor, Hogarth is by far the greatest of the British school; although in aim and object, colour, surface, and all the requisites of a great painter, infinitely below Reynolds. It would be useless to detail the perfections of a man so admired all over the earth, and who will only cease to be a delight with its existence. It is astonishing how hereditary is the hatred of academies. The painters in revenge for Hogarth's opposition, swore that he was no painter, and swear so to this hour. The absurdity of this criticism can be proved by the Marriage à la Mode, whilst the picture of the husband and wife after a rout, is as beautifully touched as any in that class of art can be. He has not the clearness of Teniers, nor the sharpness of Wilkie; his touch is blunt, and his colour deficient in richness; but you feel not the want whilst looking at him; and although his expression is often caricature, yet in the above picture it is perfection. Hogarth unfortunately believed himself infallible; but his wretched beauty of Drury Lane for Pharaoh's daughter at the Foundling, his miserable Sigismunda, and his Paul before Felix, we hope convinced him of his forte. If he was *serious* in these pictures, which we very much doubt, he deserved a strait waistcoat and a low diet as the only treatment for his hallucination.

Gainsborough and Wilson.

Gainsborough was another painter of great genius in portrait and landscape; but Wilson was a greater. His touch and feeling were comprehensive, though too abstracted for the vulgar, who always like polish and to put up their fingers. He used to say to Sir George Beaumont, "When somebody is dead somebody's pictures will sell better." From neglect he got into foolish habits of drinking and died librarian to the academy. A miserable dauber called Lambert was the fashion, and his character as a landscape painter was hit by poor Wilson. He said "his trees and foliage were eggs and spinach, and nothing more;" yet Lambert got hundreds when Wilson could hardly get shillings. But where are now the immortal Lambert's works? Making fire-screens for garrets, whilst "*somebody's* pictures" adorn the houses of the great. Gainsborough was a great portrait painter and ran Reynolds hard. West's Wolf and La Hogue are the triumphs of his talent; but his great sacred subjects are inferior works. The writer of this observed to Canova in England, "Au moins, il compose bien." "Monsieur," replied the Italian, "il ne compose pas; il met des figures en groupe." He was a skilful machinist; and though there are bits of colour in his small works, rich and harmonious, his portraits are detestable, his handling unfeeling, his drawing meagre and common. He was deeply versed in nothing, though possessing great acquired knowledge of his art without being an educated man. With respect to his being the greatest man since the Caracci. with Rembrandt, Rubens, Vandyke, and Dominichino, Guido, and Guercino since, or a little after, the idea is ridiculous and absurd. The king hated Reynolds on account of his devotion to Burke and Fox, and puffed West from sheer irritability. The king said to Hopner, "Why does Reynolds paint his trees *red* and *yellow?* who ever saw trees that colour?" Hopner, who said what he pleased, replied, "Then your majesty never saw trees in autumn."

West.

Barry.

Romney, a second-rate man, had great patronage, whilst Barry, a man of great grasp of mind, had none whatever. Barry joined the Academy to oblige Reynolds, against his own convictions; was soon at issue with its selfish monopoly; opposed it; urged the propriety of devoting a portion of its funds to establish a school of colour; exasperated the intriguers by his fearless attacks; and was expelled of course as an obnoxious man, the king having been persuaded to sanction it, under the deadly hint that Barry was a radical. Barry was the protégé of Burke, and his Adelphi pictures, shewing the progress of society, though deficient in drawing, colour, and delicacy of touch, were the first work in England on the comprehensive principle of the ancients. Having neglected Burke's repeated entreaties to dissect, he suffered the consequence. His forms at the Adelphi are such as can be got by general drawings from the antique, but there is no refined knowledge of construction in them.

Fuseli.

As a man of genius, however, Barry is not to be compared to Henry Fuseli, the friend of Reynolds and Lavater, and one of the most distinguished and accomplished men of his time. Fuseli was undoubtedly the greatest genius of that day. His Milton gallery shewed a range of imagination equal to the poet's; his Satan bridging Chaos, his Uriel watching Satan, his Shepherd's Dream, his Fairies from Shakespeare, and his Ghost in Hamlet, announce him as having conceived, like Theon, φαντασιας, and as being the greatest inventor in art since Julio Romano. But in the modes of conveying his thoughts by form, colour, light, and shadow, and above all, nature, he was a monster in design; his women are all strumpets, and his men all banditti, with the action of galvanized frogs, the dress of mountebanks, and the hue of pestilential putridity. No man had the power like Fuzeli of rousing the dormant spirit of youth; and there issued from his inspirations a nucleus of painters, who have been the firmest supporters of the British school.

But Fuseli, as a painter, must be a warning to all. Had he taken the trouble to convey his thoughts like the great masters, his pictures would have risen as time advanced; yet as time advances, his pictures, from having no hold on our feelings like the simplicity of nature, must sink. His conceptions however poetical, are not enough to satisfy the mind in an art, the elements of which are laid in lovely nature; and great as his genius was in fancy and conception, inventor as he was in art of fairies and ghosts, he will never be an object to imitate, but always to avoid by young men, who are more likely to lay hold of his defects than his beauties. The finest conception of a ghost that was ever painted, was the Ghost in Hamlet on the battlements. There it quivered with martial stride, pointing to a place of meeting with Hamlet; and round its vizored head was a halo of light that looked sulphureous, and made one feel as if one actually smelt hell, burning, cindery, and suffocating. The dim moon glittered behind; the sea roared in the distance, as if agitated by the presence of a supernatural spirit; and the ghost looked at Hamlet, with eyes that glared like the light in the eyes of a lion, which is savagely growling over his bloody food. But still it was a German ghost, and not the ghost of Shakespeare. There was nothing in it to touch human sympathies combined with the infernal; there was nothing at all of "his sable, silvered beard," or his countenance more "in sorrow than in anger;" it was a fierce, demoniacal, armed fiend reeking from hell, who had not

yet expiated "the crimes done in his days of nature," to qualify him for heaven. His next finest works were the two fairy pictures in the Shakespeare gallery, some diving into harebells, some sailing in Bottom's shoe; but beautiful as they were, indeed the only fairies ever painted, still your heart longed for nature in colour, form, action, and expression. Such an union had the Greeks, and no art in the world will be perfect until it appears again. These pictures are evidences of the highest conception of the fanciful and supernatural. His Lazar House is an evidence of his power of pathos; his Uriel and Satan of the poetical; his Puck putting on a girdle, of the humorous and mischievous. But when Fuzeli attempted the domestic, as in the illustrations of Cowper, his total want of nature stares one in the face, like the eyes of his own ghosts. Never were the consequences of disdaining the daily life before your eyes, or of affecting to be above it, so fatally developed as in this series of design; though in comparing with him another eminent artist, namely, Stothard, who, in sweetness and innocence, was his decided superior, Fuzeli surpassed him in elevation and reach of mind. In the pictures of Stothard, who painted equally well without life before him, there is not the same extravagance, yet there is almost equal want of nature in another way. Flaxman, Stothard, and Fuzeli, are the three legitimate designers of our school, and yet not one of them was perfect master of the figure.

Flaxman.

Flaxman's designs from the Iliad and the Greek tragedies are his finest works; and when first they appeared in Italy, they were denied to be the invention of an Englishman, as it was supposed to be impossible that any Englishman could have an imagination. But yet of some of these designs it really may be said, "Il n'y a qu'un pas du sublime au ridicule." It is extremely difficult to say whether they are in the highest degree sublime or extremely absurd. In all attempts to express the passions, you will perceive extravagance; but in comparing him with Canova, in this part of the art, Canova must yield the palm as much as Flaxman was inferior in the perfection of working up a single and beautiful figure. Though this eminent man talks pompously of Greek form and anatomical knowledge, he in reality knew very little of either; and though there is a great deal of useful matter of fact in his lectures, yet on the whole they display a wretched poverty of thinking. His book of Anatomy for students is not deep enough on the separation of muscle, bone, and tendon, and can help a young man a very little way to correct notions. The value of Fuseli's and Opie's lectures in comparison with Flaxman's or Barry's is evident; and the superiority of Reynolds to all, except Fuseli in his lecture on Greek art, needs not to be dwelt on.

Stothard.

Stothard, as an inventor in composition, was equal to all, but as a painter, certainly inferior to all. In fact he could not paint; he had no identity of imitation; he did not and could not tell a story by human passions; and his style of design showed great ignorance of the constituent parts of the figure. But there was a beautiful and angelic spirit that breathed on every thing he did. He seems in early life to have dreamed of an angel, and to have passed the remainder of his days in trying to endow every figure he designed, with something of the sweetness that he had seen in his sleep. Peace to his mild and tender spirit. It was impossible to be in Stothard's painting-room for ten minutes without being influenced by his angelic mind. He seemed to us always as if he had been born in the wrong planet. He had a son whose etchings from our ancient tombs are an honour to the country. He fell from a great height, in pursuing his designs from some tomb in a country church, and was killed. This ill-fated artist was in every respect worthy of his father.

Never were there four men so essentially different as West, Fuseli, Flaxman, and Stothard. Fuseli was undoubtedly the man of the largest capacity and the most acquired knowledge; West was an eminent artist in the second rank; Flaxman and Stothard were purer designers than either; Barry and Reynolds were before all the others. In Barry's Adelphi there is a grasp of mind, as Johnson said; yet as a painter he was inferior to all. Though Fuseli had more imagination and conception than Reynolds, though West put things together with more facility, and Flaxman and Stothard did what Reynolds could not do; yet as a sound, great, and practical artist, in which all the others were deficient, Reynolds must be considered the head of the British school as a painter and handler of his brush.

Opie, Northcote, Wilkie.

Opie must not be omitted, nor Northcote his imitator and contemporary, both of them men of talent. Opie, a man of great and powerful genius, issued from Cornwall at once on the town. Northcote was six years with Reynolds; and his Arthur and Hubert, and Children in the Tower, are fair specimens of his talents. He was a malicious man, and tried to injure his greatest protector, Reynolds, and Dr. Mudge who introduced him, by allowing Hazlitt to print his (Northcote's) Conversations. There never was a deeper scheme for malignant defamation. Northcote always said that *he* did not print them, and Hazlitt that *he* did not talk them; and each vented his spite on a mutual friend, and shifted the blame to the other. Reynolds was succeeded by West, and the art sunk to the lowest depth, containing only Sir Joshua's humble imitators, when a genius broke forth, David Wilkie, who rendered our domestic school, the first in Europe; and the feeling for art has been rapidly advancing amongst the people ever since. This many circumstances unite to prove.

Parliamentary inquiry.

In consequence of the perpetual complaints from the great body of artists, the government granted a committee in 1836, to examine the cause of the superiority of France in manufacturing design, as well as the condition of high art, and to ascertain if the accusations against the Royal Academy were true or false. Never in the world were the consequences of a monopoly on the perceptions of respectable men so ludicrously developed. The president and body first denied the right of the House of Commons to examine them at all; and when the persuasions of their friends showed them their folly, their appearance before the committee presented a scene never to be forgotten in the history of English painting. On all questions of finance, they proved satisfactorily the honour of their transactions; but on all questions of art more was proved against them than ever had been suspected.[1] The resignation of Reynolds, and the expulsion of Barry; the loss of a million of money to the art on the Waterloo monument, in consequence of their not replying to Lord Castlereagh's committee; their refusal to let the artists also support their exhibition, and have the same opportunities of fitting their works for the public as at the British Gallery; and, to crown all, their rendering the school of design lately established of no avail to the mechanic, by establishing a law, that the study of the figure is not necessary for his education, though it was proved that this study at the Lyons academy for mechanics, was the real cause of their superiority to us; are such indisputable evidence against their protestations of sincerity, that it has rendered the nobility and the nation more than suspicious of the truth of all the accusations which have been made against them.[2]

Scottish art.

In Scotland the art is in a promising condition, and the Scottish school in purer taste than the English. Living as

Painting.

the artists do, in the most magnificent city in Europe, surrounded by a country pregnant with historical recollections, and guided by their own shrewd understandings, the school in Edinburgh will, before many years, take a very high rank in the art. But there is some cause to apprehend that it will be checked at its most critical period, from the usual cause, the foundation of the old curse of Europe, an academy. After having produced Runciman, Raeburn, Wilkie, and the other eminent men Scotland can boast of in art, they have been persuaded to found conventional distinctions, in favour of a select few; and, as elsewhere, the result will be the same. No Wilkie, no Runciman, no Raeburn will come from it; for the best men they now possess were eminent before it was thought of. The art has no business with any aristocracy of talent. Conventional distinctions, which are not hereditary, are laughable and absurd; and distinctions which are, ought to be reserved for high descent, heroic actions, landed property, or vast political genius. Such an aristocracy produces heart-burnings and injustice; for it places power in the hands of men, who are not amenable to justice for tyranny, and who cannot be reached by law, for calumny or insinuation. "Of all hatreds," said the *Edinburgh Review*, "there are none to equal the hatreds weak men in power bear to the man of genius without it." It is a curious evidence of the sagacity of the Scotch, that whilst the English portrait painters, since the death of Reynolds, were all placing kings and queens on their toes, from sheer ignorance of perspective, Raeburn, Wilkie, and Gordon have never made that mistake.

In a word, it is our decided and unprejudiced conviction, that the genius of the British people, will never have fair play or be soundly advanced, till the Royal Academy is removed, or effectually remodelled; and this will be effected either by the positive interference of the queen or the government, or by the rapidly increasing knowledge of the people. If the capital and the provinces were freed from the predominance of those men; if the honours were abolished and the constituencies restored; if the whole national galleries were turned into a great school, with branch schools in the great towns; if the Cartoons were removed to London for the occasional sight of the people, as they might be inclined to drop in; and if a Native Gallery were arranged for the best productions to be purchased as they appeared, and the House of Lords adorned with a series of grand works referring to the British constitution; then would the government do a real good to taste, refined pleasures, and design for manufactures, such as would entitle them to the everlasting gratitude of the nation.

On the other hand, if all the ancient boroughs of the land have been obliged to bend to the call for reform; if the crown itself has been obliged to yield up the old House of Commons; if the salaries of our great officers of state have been cut down without complaint; if pensions bestowed equally for merit or for vice, are to be rigorously sifted; if the queen herself has been obliged to permit her expenditure to be questioned; are a set of men without a lease of their House, or charter for their existence, without any one legal claim to be considered as a constitutional body—are *they* alone to brave the Commons and the Lords, are *they* alone to defy and deny reformation, taking their stand upon their utter insignificance? If so, it will be an anomaly in the character of the British Legislature, which, in after times, will only be remembered as a proof of imbecility and folly, if not of something still worse than either.

General deductions.

We have now gone through the great leading schools of Italy, France, Germany, Flanders, Holland, Spain, and Britain, and we have taken those names only, which may be considered as leading an epoch; so that, in such a system, many eminent men must of necessity have been omitted. From the Petersburg, Copenhagen, Berlin, or Stockholm academies, no great genius except Thorwaldsen has yet appeared.

Was Italian art equal to Greek art? Certainly not. In the finest Italian there is a want of beauty in form and face, which Greek art could only supply. Poussin said, that Raffaelle was an angel in comparison with the moderns, but in comparison with the ancients he was an ass. Though this is vulgar, it is in our opinion true. The ancients combined the Venetian and Roman schools; they considered form, colour, light and shadow, surface, expression, and execution, as all equally component parts of imitation, and all necessary to perfect that imitation which was to be employed as an instrument to convey thought. They combined the drawing and the colouring of the two great Italian schools; as these illustrious schools tried to do when they found out their error, in pursuing one at the expense of the other.

Reynolds, from the defective practice of each school, laid it down that colour was incompatible with high art; and he also laid it down that the ancients could not be great painters in a *whole*, though they might be in a *solo*, from the pictures on the walls of Pompeii. We do not wonder at any man so concluding before the Elgin marbles arrived; but we do marvel at Reynolds taking the works in the private rooms of a provincial Roman city as justifiable grounds on which to estimate the extent of genius in Greek art at its finest period, five hundred years before. But after all, what are the pictures of Pompeii? Very probably the designs in Pompeii would rank about as high in ancient art, as the designs of our paper-stainers in Bond Street would in British art. The pictures at Pompeii are no more criteria of what the art of Apelles and Polygnotus really was, than any sculpture dug up there would be a criterion of what the art of Phidias was. Reynolds undervalues contemporary praise; but Quintilian, Cicero, Horace, Juvenal, Strabo, Polybius, and Pausanias, Valerius Maximus, Ælian, and Pliny, were not contemporary; and, therefore, the praises of Aristotle or of Plato who were, justify the enthusiasm of those who were not.

Since the works of Phidias arrived in England, we have positive evidence that the Greeks knew the great principles of composition and grouping, as applied to painting; because the metopes are instances of arrangement of line, that will do exactly in a picture, if the Laocoon had not shown it before. Having now seen the Elgin marbles, which the Greeks estimated as their finest work, and having found all the enthusiasm of the ancients more than borne out, have we not a justifiable ground to argue from what we *do* see in one art, that what we do *not* see in another was equally excellent? Will any man, after seeing the Theseus and Ilyssus, doubt that the ivory Minerva and Olympian Jupiter were equally, if not more beautiful? Why should the ancient critics have faith placed in all their decisions except those on painting? Why should they lose their perspicacity of understanding only when they talked of this art? After Aristotle and Plato had admired the Minerva inside the Parthenon and the sculpture outside, they might admire the pictures; and nobody will deny them the power of making comparisons. Had the Elgin marbles and the old antique never been seen, would not the same sophistry have been put forth to question the merit of their sculpture as well as to deny that of their painting? "Nothing can be more perfect than Phidias," says Cicero. "You cannot praise him enough," exclaims Pliny. "He made gods better than men," says Quintilian. "He was skilful in beauty," says Plato. You believe all this, because you cannot contradict it; but the moment Quintilian says, "Zeuxis discovered light and shade; Parrhasius was exquisite for subtlety of line; Apelles for grace; Theon for poetical conceptions (φαντασιας); Pamphilus for mathematical principle; Polygnotus for simplicity of epic arrangement in colour and form; Protogenes for finish;"—when Pliny commends Aristides for expression, and Amphion for composition, and speaks of the grand assemblage of the gods by Zeuxis, as well as the single figures of Apelles, Reynolds

replies, "Admiration often proceeds from ignorance of higher excellence, I will not believe contemporaneous praise." We answer, that admiration oftener proceeds from knowledge of superior excellence; that the most enthusiastic admirers of Greek painting were not contemporary; and that Reynolds' conclusions against Greek art are founded upon data which are altogether erroneous.

Taking the Elgin marbles as a standard, we cannot but suppose that the finest great works of Greek art had the finest drawing, the most wonderful knowledge of form, the finest grouping, and the finest expression. To this may be added, colour from Pliny, light and shadow from Quintilian; perspective from Vitruvius; fore-shortening, dwelling on the leading points, like Vandyke, and touching off the inferior parts from Plutarch; and, what was never suspected, execution with the brush from Horace, on the leading principles of the Venetians. The French used to affirm, that David's principle was the same as that of the Greeks, namely, obtruding on the attention all the superior parts, and neglecting the inferior ones. In Plutarch's life of Alexander, at the very beginning, he describes to his readers his plan of writing his lives, and concludes with this extraordinary passage: "Like painters that paint portraits, who dwell on the face, caring little about the remaining parts."[1] His meaning is, that he would, like painters, dwell upon the leading points in the history of great men and lightly touch off the inferior parts. Could he have made such an allusion for the general reader, if this had not been the practice of the great Greek painters? Again, Horace says in the art of poetry,

> Ut pictura poesis erit; quæ si *propius* stes,
> Te capiat magis; quædam si *longius* abstes.

That is, some pictures are painted for a close, others for a distant inspection. The former, of course, are wrought up; but in the latter, the leading points are seized by a touch, leaving the atmosphere to unite. As to mere handling of the brush, this is conclusive, and shows that it was done on the same system as by Titian, Tintoretto, and Velasquez. Reynolds has quoted Pliny's description of glazing, that is, spreading a thin transparent tint over the crude colours to bring them into harmony, which was the practice of the Venetians. Another passage completes the conviction: "Adjectus est *splendor*, alius hic quam lumen, quem quia inter hoc et umbram esset, appellaverunt *tonon*." (Lib. xxxv. c. 5.) "Now was added *splendor*, a different thing from light, and which splendor, because it was between light and dark, was called *tone*." To the mind of an artist this is exquisite in distinction; first, the colours on the tablet were fresh, unmixed, and raw; then was spread over a transparent glaze to take off the crudeness; then this crudeness being reduced, it was called *splendor*, glowing, rich, and deep, but different from *light*, which is cold and white; and this splendor the Greeks called *tone*, as both the Venetians and the British denominate it. But the circumstance of tone being the characteristic of any school, is proof of an age for colour.

As to their perspective, let any man consult Vitruvius, (lib. vii.). Agatharcus composed a treatise on the subject; and from this hint, Democritus and Anaxagoras wrote on perspective, explaining in what manner we should, in appearances agreeable to nature, from a *central point* make the lines to correspond with the eye and the direction of the visual rays, and render the scene a true representation of buildings, that those objects which are drawn on a perpendicular plane, may appear some retiring from the eye, and some advancing towards it. From a passage in Plato, it is clear, that the Greeks carried the illusions of theatrical perspective to a much greater extent than, in consequence of some bad landscape discovered in Herculaneum has been supposed."[2] That they foreshortened is clear, from Pliny's description of a bull coming out of a picture frontways.

The inferences to be drawn from all this, are, first, from Plutarch and Horace, that the Greeks had execution like Titian and Vandyke; secondly, from Pliny, that they must have had fine colour (lib. xxxv.); thirdly, from Quintilian, that the principles of light and shadow were understood (lib. xii.); fourthly, from Vitruvius (lib. vii.), that they had sufficient perspective to make objects recede and advance; and fifthly, from the Elgin marbles, executed by and in the school of Phidias, who was first a painter, that they had expression, form, and composition. If the three most important can be proved, as they can, and colour, light and shadow, and execution, more than inferred; what right has an eminent English portrait-painter, grossly deficient as a painter of high art, to assert, that they could not be great in extensive compositions, because the painted walls of a provincial city gave no evidence of such excellence in their private houses? forgetting that these were executed five hundred years after the eras of Greek perfection, when Greece was a Roman province, when her cities had been sacked, and her art was talked of as a wonder that had passed away.

Conclusion.

The principle laid down for high art has been, that the lower addresses the eye and the higher the mind, and that the union of the two was incompatible; whereas, the true principle surely is, that both styles address the mind through the eye, but in different ways; the lower walk making the imitation of the actual substance the great object of pleasure only; and the higher walk making imitation the means of conveying a beautiful thought, a fine expression, or a grand form with greater power. The imitation though more abstracted must not be less real or effective. Sir Joshua Reynolds affirmed, that the look of truth which fine colour, light and shadow, and reality gave, distracted the eye from the poetry of the conception or the depth of the expression. But it may be maintained, that in an art, the elements of which are laid in imitation, the beauty of an expression, the grace of a motion, and the sublimity of a conception, will be *increased* in proportion to the look of *reality* in the objects; and the practice of all the great Greek painters, and of Raffaelle and Titian in their latter works (the Transfiguration, and Pietro Martyre), proves that they had come to the same conclusions. Yet Reynolds, with his usual sagacious policy, appears to waver lest he should be wrong. "There is no reason," says he, "why the great painters might not have availed themselves with caution and selection of many excellencies in the Venetian, Flemish, and Dutch schools; there are some not in contradiction to any style, a happy disposition of light and shade, breadth in masses of colour, the union of these with their grounds, and the harmony arising from a due mixture of hot and cold tints, with many other excellencies which would surely not counteract the grand style." And then he concludes that "a subdued attention to these excellencies must be added to complete a perfect painter." This is all that is contended for. So far from these excellencies being incompatible with grandeur of style, they are essential to it, they are the elements and the basis of it, they cannot be left out, or if they are, the style is deficient, absurd, and not founded in nature. There is not the least doubt that the Greek painters considered the power of imitating natural objects by colour, and light and shadow, as necessary and requisite in preparatory study as drawing or composition; and the greatest painters in the grand style in ancient Greece, were

[1] —— ὠσπερ ουν οι ζωγραφοι τας ὁμοιότητας ἀπο του προσωπου, ἀναλαμβανουσιν, ἐλαχιστα των λοιπῶν μερων φροντιζοντες. ΑΛΕΞΑΝΔΡΟΣ.

[2] *Theatre of the Greeks*, p. 262, 3d edition, Cambridge.

just as capable of imitating still life as the possessors of it now.

It may, therefore, be fairly deduced, that the Greeks possessed all parts of the art, and none particularly to the exclusion of others; that, therefore, all parts of the art, in due subordination, may be considered as essential to an artist of the highest walk, as also in the more humble department; and that the system of Reynolds, which excludes identity and power of reality from judicious imitation of the objects painted, combining colour and light and shadow, as well as expression and form, is *false*, and should be exploded from all systems where art is considered as a matter of importance to the dignity or glory of a nation. (B. R. H.)

Supplemental remarks.

Since the foregoing article was written not more than twelve years have passed, but in that short space the art of painting has undergone such changes in theory and practice that many opinions then unhesitatingly proclaimed, and received without a doubt, if propounded now, would be thought ridiculous; for, while it may be confidently stated as an admitted fact, that modern art in this country is at present much more generally appreciated, and receives far higher encouragement than it ever did at any former time, it is equally true that this favourable state of matters has arisen under a system founded on principles in many respects directly opposed to those that not many years ago were generally laid down as indisputable. In place, then, of altering the foregoing article by striking out or modifying such statements as were based on notions formerly held regarding art, but which are now untenable according to those now entertained, it has been thought a preferable course to endeavour to point out some of these changes, and to show how they have operated; and so, to some extent, the soundness of the opinions given in the first portion of this article will be tested by an examination of the practical results of the art of painting at the present day.

Within these few years several questions that agitated the British school from its commencement have received a trial, and to a considerable extent may be considered as settled. Art, therefore, having greater freedom of action, has assimilated itself more to natural tastes, and opened resources of pleasure and enjoyment that at one time, from notions now deemed false and pedantic, were not thought to be within its proper province. The invention and rapid development of photography within this period has also operated powerfully in the settlement of these questions.

The following were the chief points so long and so vehemently put forward:—1. It was maintained that art would never reach a high position in this country till it was patronized by the church and the state; that our art was crushed by the Reformation; that pictures were excluded from churches by bigotry and ignorance, for as they tended greatly to excite devotional feeling, they might be beneficially employed in religious services; that the old masters of Italy, Germany, and Spain were always engaged on Scripture subjects; and that the British school of art never would rival or approach the schools these great painters founded till its artists received similar employment. 2. It was pointed out that little or nothing was done publicly for the encouragement of art; and it was said that the only way in which this could be carried out was by government ordering the execution of large works illustrating the history of the country, such works to be placed in palaces and national buildings, to which access should be afforded to the public. 3. Fine-art academies, of which the Royal Academy is the exemplar, were strongly condemned. The opponents of academies declaimed loudly against such bodies asking and receiving grants from government in the shape of money or accommodation for their schools and exhibitions. "Are they not," they said, "close corporations for accumulating funds with which they pension aged members or the families of deceased members? while in their exhibitions they appropriate the chief places, favourably to display their own works, and give only inferior situations to the works of artists who have not had the good fortune to have been elected into their body. Academies and exhibitions ought to be put down."

As before stated, all these questions may now be considered as in a great measure set at rest. At the present day paintings for churches used by Protestants are rarely commissioned; and though the decoration of churches engrosses much attention, painting, except in the limited and conventional mode as applied to glass for windows, is never resorted to; the unsatisfactory result of the efforts lately made by government to encourage art by competitions for frescoes and historical paintings has set at rest the point of government patronage of art; and academies and exhibitions never were so popular and flourishing as they are at present.

Government patronage of high art.

Glancing hurriedly over the pages of the history of the British school from its commencement, one cannot fail to notice how much the founders deemed it an almost incontrovertible principle, that encouragement of art by the church or by government was necessary for the growth of a national school in Britain. Sir Joshua Reynolds spent much valuable time in inculcating this principle and in trying to prove it practically. Barry devoted his whole life to what has been styled high art; and from his time till within a few years of the present period, this has formed the theme of numerous writers on art, and has guided the practice of various British artists, the chief among whom were Benjamin West, Stothard, Hilton, and Haydon. The last of these saw accorded in some measure what they, and he himself, the most eloquent and energetic of them all, had so long contended for,—namely, a trial (with reference to the Houses of Parliament) given by the government to their cherished notions, that church or state employment was the only true patronage for art; and he, the only remaining representative of these opinions, was at last borne down by bitter disappointment at finding that the benefits to art so long and so confidently predicted were not realised by that trial.

It is manifest that the result of this trial has been beneficial to art. The slavish adherence to rules and precedents founded on what has been done in former ages, without consideration of the important fact, that the wants and the enjoyments of the people of these past ages were very different from those of the public now, has been abandoned; and art now flows for the use of the public in its natural course, unobstructed by those impediments to the vigour and originality of a national school.

No doubt it was natural that at the foundation of a new school the rules and precedents of celebrated schools in former times should be greatly relied on; childhood requires support, and youth needs guidance and restraint. And this accounts for what is often noted as extraordinary conduct on the part of Reynolds,—namely, his having constantly impressed on artists the necessity of attending to the rules of the old painters, and having held up the style of the Caracci, and of Ludovico in particular, as a safe model for the artist to study. He formed this notion from the consideration that the style of the Caracci was based on rules and precedents; and therefore he reckoned their works as well fitted to exemplify what he reverenced. It has been most unjustly alleged that Sir Joshua strongly urged his brother artists and his pupils to follow out historical painting on a grand scale, or on what were called high-art principles, not from his having any faith in those notions himself, but from the unworthy motive of diverting their attention from the field of portrait-painting, where he gathered riches and

fame. This is absurd; he is entitled to full credit for the sincerity of his opinions. As a member of a school at that time in its infancy, when lecturing and theorizing on art, he was to a great extent trammelled by being obliged to refer to the maxims and examples of ancient schools; for it was by reference to the works produced in them that he was to direct theoretically the members and pupils of the rising school. In this respect he was not able, or had not confidence enough, to go much beyond the opinions of his day. And we cannot doubt his sincerity; because he misspent much valuable time in trying to put these very theories into practice in the form of large historical compositions and allegorical figures,—for example, those executed for the windows of New College, Oxford;—and he freely offered still further to waste his talents, and paint a Scripture subject to be placed in St Paul's. As a writer or lecturer on art, Sir Joshua was no doubt the first in his time; but his theories were just the theories adopted generally by the world at that period,—clearly and elegantly given forth, and mixed here and there with such opinions bearing on the practice of art as only an able artist could enunciate. But it was by his pictures that he gained a name for himself, and contributed so greatly to the glory of the English school. The opinions in his time inclined to a certain style of art as alone worthy of notice; he was carried along by these notions to the extent, not only of theorizing on them, but of wasting time in practising them; but his genius, as it were, in spite of himself, carried him beyond what, walking by rule and measure, he thought the proper line, and he executed works which, though then little esteemed in comparison with what were called his historical compositions, are those on which his fame now chiefly rests. What the public now prize are his portraits,—admirable embodiments of distinguished men and lovely women,—and his simple and natural representations of the freshness and purity of childhood. His laborious efforts to emulate the Caracci in depicting the "Death of Dido," or the "Continence of Scipio," attract but little sympathy now; and, as property, would be valued far lower than his portraits of Lord Heathfield or Nelly O'Brien, or his "Girl with a Mousetrap," "Strawberry Girl," or "Shepherd Boy." It is recorded that the former works cost him many months of toil and trouble; that the latter were hit off with little effort. The same rules that hampered but could not restrain the genius of Reynolds, operated, however, very differently on men like Barry and others, who were gifted with considerable talent, but not genius to give them courage to step out of what they looked on as the circle of established art. Barry was ardent, and had high aspirations and much determination and self-will. His friends, and he himself, mistook these for the elements of great genius; but what was the result?—works that, looked on in the most favourable way, must be pronounced to be merely imitations or reflections, or as got up on the model of those executed in countries at former periods by painters who very probably responded to, or worked in unison with, the feelings of their own age and country, but whose productions are chiefly to be distinguished by qualities which were not cared for, and elicited no sympathy from the English public in Barry's time. The dilettanti and the writers on art of the period vehemently maintained the necessity of working as the old masters worked; and the English school, being then but recently instituted, and most of the artists of the time having been indoctrinated with these notions, could not at once cast them off. Indeed, men like Reynolds and Gainsborough, and even Hogarth, with all his originality, could not entirely free themselves from such influences; but their genius eventually, by the works they executed, carried them beyond every such bias. Since then the English school has been getting gradually out of these trammels, and assimilating itself more and more to the tastes and feelings of the times. Wilkie, Turner, Raeburn, Bonington, Constable, Etty, and many others, and their successors, the artists of our own time, are producing, and have produced, works of such importance that the artists of the British school, in place of looking on the works of the old masters as unapproachable examples, can show works, some rivalling those of the old masters in many of their best qualities, and others executed in successful opposition to rules and principles formerly considered as beyond dispute.

It is remarked in Cunningham's *Lives of the British Painters*, that Reynolds "had amassed a fortune, and obtained high fame in abiding by the lucrative branch of the profession, whilst he (Barry) had perched upon the unproductive bough of historical composition, and had not been rewarded with bread." But it is needless to occupy more time in showing that Reynolds, when he talked learnedly on high art, did so honestly and sincerely, from convictions formed in his mind by education and imbibing the opinions of those with whom he came in contact, and not for the purpose of leading Barry away from that road along which he himself was impelled by his genius, in spite of all conventional theories. What had he to fear in competition with Barry? In his own proper walk he ranks with the greatest artists the world has produced. Among the *chefs d'ouvré* in the Manchester Exhibition by Titian, Rubens, Vandyck, and Velasquez, were there any superior to Sir Joshua's "Nelly O'Brien?" In his day poor Barry, perched on his "unproductive bough," doubtless looked down with great contempt on such works as Sir Joshua's "Nelly O'Brien" or "Robinetta," and consoled himself with the reflection, that posterity would do justice to his claims, and confirm the plaudits of the scanty knot of dilettanti admirers who gazed up at him. And all the painters since Barry's time who have perched on the same bough have experienced similar treatment, varied merely in degree. West had a larger number of admirers than Barry; among these was George IV., who commissioned him to execute various works; and the artist acquired considerable riches and a certain temporary popularity, but this barely lasted his lifetime. His works are held in little estimation now. Some of Fuseli's fanciful compositions, when transmitted through the medium of engraving, attracted for a time a degree of notoriety. Stothard's fame will rest entirely on his designs and small compositions. Etty can scarcely be classed among those who maintained the claims of high art; his fame rests on other grounds,—namely, his having most powerfully aided in increasing the strength of the English school in an art element that has always entered largely into it; and his works now rank with those of the greatest colourists. Haydon may truly be considered the man who, by his paintings, and especially by his writings and lectures on art, made the chief efforts to uphold those notions as to art, and government patronage of art, which led to the trial and settlement of the question. There can be no doubt that his energetic appeals had great influence. The extraordinary facilities afforded by the erection of so vast and magnificent a pile as Westminster Palace and the Houses of Parliament were taken advantage of by government, and a fair trial was given to the artists of the country. But though there was no lac' of talent displayed, the results have not justified expec' tions. It is now seen that all that government will do, or can ever be reasonably expected to do, must weigh as nothing in comparison with the encouragement annually given by the public, which is patronage of the healthiest kind, and rapidly increasing year by year; that painting on walls does not suit the style of the buildings in this country, being often at variance with those notions of comfort and convenience which prevail in our arrangements; that fresco-paintings encounter great risk of damage, from their surface affording so slight a resistance to anything coming it contact with it,—those on the walls of the

arcades of the public gardens at Munich, for instance, require so often to be patched up with tempera colours, that, though only executed about twenty years ago, they can scarcely be called fresco-paintings now. Besides, paintings are objects which bear great value; and in a mercantile community like ours, when money is invested in that way, facilities for disposing of such property are necessary. Few would think of laying out ten or twenty thousand pounds on pictures attached immoveably to the walls of a mansion, while many invest such sums in pictures that are portable; and these investments are often very profitable, while the capital employed may speedily be realized by sale or transfer. The chief arguments in favour of large pictures for public buildings were drawn from the example of foreign states, particularly France. But public taste in this country does not run in a channel similar to that in which it flows in France. With us art is to a great extent domesticated; in France it is government, on whom the people rely for many of their enjoyments, that has generally made use of its services. But now, even in France private employment is preferred by the principal artists to government patronage; they find that they are better remunerated by private purchasers or by publishers than by government. Artists like Vernet, Scheffer, Delacroix, and others, now see that their works of moderate size are eagerly sought after; and it is a great loss to them, not only in money, but in fame, to engage on large government works. Although great numbers go to look at their pictures in public buildings, those executed for private individuals are seen by many more, for they are exhibited all over the world. That the remuneration is greater for pictures of moderate dimensions is proved every day: for example, at the sale of the Duchess of Orleans' collection of modern works of art, a cabinet picture by Delaroche, about 3½ feet by 2 feet, brought L.2300,—more than double the sum paid to him for two years' labour on cartoons for pictures for the church of the Madeline. Government patronage, too, often involves elements distasteful to a high-minded man conscious of the position his talents entitle him to. For instance, when Delaroche was labouring in Rome at his cartoons for the Madeline, by court influence another painter was associated with him in painting this church, although there had been an understanding that the whole work was confided to Delaroche. Indignant at such treatment, he threw up the commission, and returned the money that had been advanced to him when he was engaged on the cartoons. Thus was the labour of two years of a man of high talent entirely lost. In that time he might have executed several works of great importance, which, exhibited in various countries, and circulated by engraving, would have yielded him money and reputation, besides spreading the taste for art. Even in France it seems likely that art will soon rely very little on government support.

The notions of Haydon and others, that the future of art in England depends on government employment for artists, and that if pictures are painted for private patrons only, they will sink to the level of mere decoration, will be assented to when it is admitted that no artist can be a great painter who does not paint subjects from Scripture, heathen mythology, or Greek and Roman history—the figures either nude or in conventional drapery, and at least 7 feet in height; and that the only competent tribunal for deciding on works of art is a committee, the members of which are selected on account of their rank, official status, or reputed dilettantism.

Academies and exhibitions.

The cry against academies, and against exhibitions, which are the chief features and supports of academies, has, of course, in a great measure gone down with the one that was simultaneously raised,—namely, government patronage and high art. Can anything better be devised than the open arena of an exhibition, on which every artist competes before, and is judged by, the public? No doubt, it may be said, this would be all very well if every one had the same chance; but some works are hung where they are seen to great advantage, while others are so placed that they cannot be fairly appreciated. But really, is there any human institution that is perfect? Every work cannot be put in an equally good place, and some sort of classification is necessary. Of course, the best works should have the best places; but difference of opinion may arise here. The works of artists who have attained a reputation will naturally first be attended to; that is but fair. These artists, in their early days, were obliged to struggle for their position. But is it not evident, that to the rising artist the opportunity of having his works in a public exhibition is an advantage of the highest kind; while to the more advanced artist it must operate as a spur to continued exertion. If the works of the former evince improvement, they will gradually make way; if those of the latter become less attractive, they must give place. In exhibitions public opinion is a ruling element. In one of his lectures Haydon gave a graphic account of a meeting in Wilkie's apartment on the morning of the day on which the exhibition of the Royal Academy was opened. On the previous day, at the private view, Wilkie's picture of the "Village Politicians" had been very much noticed; large offers were made for it; and a most favourable criticism had appeared in the newspapers. Haydon had seen the criticism, and had rushed to Wilkie's to inform him of his success. The road to fame and fortune was now opened to the hitherto unknown artist; and how? By means of the exhibition. Wilkie's picture had been commissioned by a noble patron; when nearly finished, it had been shown to this patron, but he had demurred to the price. If there had been no exhibition to which Wilkie could send his picture, he probably would have been obliged to have lowered his price; at all events, he would only have been paid grudgingly the very low sum he asked; and though he had been fully commissioned to go on continually at similar prices, he would barely have made enough to maintain himself in the small lodging he then occupied. But by the exhibition he was enabled to bring his productions before the public, contrasted with the works of established artists who were handsomely remunerated for their pictures; and by this comparison the high qualities of Wilkie's picture were fairly estimated, and a much higher value put on and offered for it than he had ventured even to think of. In opposition to all Haydon's objections to academies and exhibitions, could any argument stronger be brought forward than the simple narrative of the above anecdote? In truth, it is by our annual exhibitions of modern works that art is maintained in force in this country; for they are in every way calculated to lead to the best of all results—originality, variety, and adaptation to the feelings and requirements of the age.

But though it cannot be denied that art is in a prosperous condition, and that this state of matters has arisen just at a time when public exhibitions and academies are more encouraged than they ever were; yet by some people academies and exhibitions of modern art are opposed and decried. It is not very likely that these institutions will be at all damaged by such assaults; they will probably be benefited by them. Their strength and importance will thus be made still more evident; and by those who conduct them reforms and improvements will be adopted to make assurance doubly sure. Haydon, and objectors of his class and time, denounced academies and exhibitions because they interfered with their favourite plan of government patronage; but when it came to be seen that government commissions were as nothing compared with what was expended on art by the public, these objections fell to the ground. They also opposed the Royal Academy for reasons of a personal kind. They felt sore that they were not elected members of that body. No doubt Haydon, John Martin, and some others of that time,

possessed higher qualities as artists than many who shared the honours and privileges of academicians; yet, on the other hand, there were many other members of the Academy, who, as artists, ranked much above Haydon and Martin, who submitted to the ordeal of election, and did not get up a feeling of indignation because they were not elected on their first application. It is scarcely to be expected that the academicians, who are the electors, are never to err in their judgment. Judges and juries sometimes err; but, with all its drawbacks, to this mode of election most of the greatest artists of this country have submitted. No better mode has yet been devised,—at least none better has been successfully practised; at all events, it is a preferable mode to that of allowing a competitor to be the judge of his own claim, which, in plain words, is just what the objectors demanded.

Cognoscenti.

Objections now-a-days are raised chiefly by cognoscenti,—namely, such as consider themselves, by education and taste, better qualified than artists to decide on art, and all matters that bear on it; but the flimsy attacks of such can cause but slight annoyance. The elements necessary to give a title to be classed as an art-connoisseur in the days of good old Sir George Beaumont seem to have been various and important. He painted landscapes, he had formed a collection of ancient pictures, and he commissioned modern works. But now-a-days the title of connoisseur is assumed on very slight qualifications. There are few amateur painters now. The uselessness of such an occupation is demonstrated by photography, for since that discovery, no sketchy or conventional mode will be tolerated as a representation of nature. If a man is to paint, he must devote his life to it. An hour snatched from business or pleasure for such a purpose is just so much time thrown away. Hence many who have that sort of liking for art that impels them to dabble in it,—pushed aside by the photographer, have no vent for their tastes and feelings but in criticising artists and telling them how to paint. And as a glance at some of the continental collections, and a few months' residence in Rome, are thought undoubted qualifications, this class of connoisseurs is large, and supplies most of the objectors to modern art and modern exhibitions. Again, touching the title to connoisseurship on the ground of possessing a collection of ancient pictures, the acquisition of genuine works of celebrated painters of former schools is within the reach of few. When such occur for sale, they are purchased for public galleries, and nations compete for them. A sum exceeding L.20,000 was lately given for one specimen of Murillo for the Louvre, and more than L.13,000 for a work by Veronese (a purchase that has received the full approval of the public) for the National Gallery of London. The ridiculous notion that possesses some people of a chance of purchasing at sales Correggios, Rubenses, &c., of marvellous value, at marvellously small prices,—in truth, a species of gambling,—is fast going out; and the facility with which picture-dealers can supply the most extensive demands for works of the old masters has led purchasers, by making a very simple calculation with reference to the average ages of painters, the time necessary to paint a picture, and the number of works ascribed to every artist of name, to arrive at the conclusion that not one in a hundred—in some instances, perhaps, not one in a thousand—of the pictures ascribed to old painters could have been executed by them. Hence, in these times of practical men and measures, the possessor of a collection of the old masters is not, without considerable scrutiny and hesitation, admitted to rank as a connoisseur.

Estimation of art by the public.

The patronage that Sir George Beaumont and other kindred spirits bestowed upon British art, though highly honourable to them, was very different from that now accorded by our merchant princes. In the early days of art in this country our artists scarcely knew their own powers. If they ventured to compose works in any way differing from those of the old masters, they were not only accused of heresy, but took guilt to themselves. Sir Joshua Reynolds held up Ludovico Caracci as a model, though he himself was a much superior painter. Wilson constantly referred to Claud; and before he died the name of Vandyck was among the last words Gainsborough uttered. At the beginning of the century this feeling still prevailed. Patronage of modern art was only hesitatingly given, and occasionally the patron accompanied the commission with directions how to execute the work required by him. It is recorded that Sir George Beaumont deemed no landscape completed till a brown tree, in the manner of the ancients, was introduced, and could scarcely preserve his equanimity when Constable bluntly questioned the soundness of the maxim. Now, however, the extent and value of the various collections of modern art in London and the other emporiums of manufacture and merchandise is quite marvellous. The collections of Wells of Readleaf; Barnard; Arden; Bicknell; Ditton of London; Miller of Preston; Eden of Leatham; Newsham, Preston; Fairbairn, Hull; Ashton, Manchester; Naylor, Houldsworth, and J. Miller, Liverpool; Gillot, Birmingham; Houldsworth and Dennistoun, Glasgow; Graham, Lancefield; Wilson, Banknock; Caird, Greenock, are all very important, several of them of immense value. And these and similar collections for the most part have been formed, not with the view of qualifying their possessors to be ranked as connoisseurs,—though certainly the frequent exercise of judgment must lead to knowledge,—but on the sound principle of making art the means of imparting to themselves and their friends pleasure of a highly intellectual kind; while from the exercise of those large but keen views that enter so much into the mercantile character, the sums invested on art-property are in most cases at any time capable of being turned to good account. Thus the great vigour displayed by art in this country, and the enormous patronage bestowed on it by the public within these few years, must be set down to the circumstance of its being now admitted by artists, and the public generally, to be a settled principle, that in a community socially and politically constituted like ours, art cannot and ought not to depend for encouragement on government patronage. Freed from the notions of government employment that obstructed so many of our painters some years ago, the artist can now give his whole attention to produce a work that will interest the public, from its attracting sympathy by touching the feelings, or by recalling and illustrating past events of importance, or by perpetuating momentous occurrences of the times, or by placing before the eye scenes of beauty or grandeur; and when this is done, he knows his efforts will not pass unnoticed, for in the exhibitions now opened in all our large cities, his productions, if up to a certain standard, will be admitted and brought before an assemblage eager to find out works evincing talent, and, by praising and purchasing them, to reward the artists by whom they are executed.

Pre-Raphaelitism.

What is called the pre-Raphaelite movement is one of the results of the change in the notions of our artists regarding the study of the old masters and high art, though it must be admitted that the invention and development of the science of photography greatly aided it.

The question so frequently put,—namely, What is it that distinguishes the style of art called pre-Raphaelitism from other styles of art?—is answered in so many different ways that it is manifest the ideas of most people regarding it are quite undefined. Some say that it is a style of art modelled on that of the artists who painted before the period of Raphael, in whose time the classic element which shortly before had been superinduced on the Gothic, had entirely superseded it; that though by this, art gained many high qualities, it lost several of greater importance, particularly truth

and simplicity; and that pre-Raphaelitism aims at returning to the purity and simplicity of the style of these old painters. Others allege that it is an attempt to represent nature as truly and faithfully as the means employed will allow, neither omitting, nor adding, nor changing anything. But the explanation oftenest given is, that it means a style of painting involving great labour and careful and minute execution, or what, technically speaking, is called *finish*.

Now, though in each of these attempts to define what pre-Raphaelitism is, some of the elements that enter into it are pointed out, yet by none of them is a complete explanation given of it, while a combination of all these definitions would involve contradiction. For instance, the very name the followers of this style have adopted implies an assimilation to the style of the art before Raphael's time; but though in the works of many of these old painters we find several high qualities, a very close resemblance to nature assuredly is not one of them. We no doubt see that an effort is made to attain it, and that may be pointed at as a sufficient motive; but again, these old painters knew nothing of breadth, and not much of light and shadow; and pre-Raphaelites constantly aim at these qualities (particularly the latter) in their works. Then, as to its being merely a faithful representation of what the artist sees, that would be putting his work on a level with one produced by machinery; this notion is evidently based on exaggerated ideas raised by too much reliance on photography, which, though extremely useful, is only an auxiliary to art. While to make minute finish the distinguishing feature of pre-Raphaelitism would be assigning to it by no means a high position; and, indeed, in the works of several painters we find many of the faults which pre-Raphaelites strongly censure united to very high finish.

But, indeed, pre-Raphaelite art has even already undergone modification; and what has lately drawn forth bitter ridicule from some, and inflated praise from others, is rather an excrescence on a style which is entitled to high praise as one of the many vigorous efforts by which British art, emancipated from the notions and prejudices that so long have clogged it, has established its claim to originality and power.

On reviewing the state of painting in Great Britain, it may be truly said that our artists, freed from conventional rules, having cast aside vain notions of government patronage, and aided by those appliances (photography chiefly) that science has put within their reach, now study nature with the greatest earnestness and success. And the numerous opportunities afforded by exhibitions, of bringing their efforts before the public, rapidly improving in taste and in ability to appreciate and reward art,—has led to such results, that many of the works of the British school, even in our own day, will compete successfully with those of the most celebrated ancient schools that have conferred honour on the countries where they flourished. (W. B. J.)

PAISIELLO,[1] GIOVANNI, a very distinguished Italian musician, was born at Taranto, in the Neapolitan States, on the 9th of May 1741. His aptitude for music having been early remarked, he was admitted, in May 1754, as a pupil of the Conservatory of St Onofrio at Naples. There he received lessons from Durante, and afterwards from Cotunni and Abos. In 1759 he obtained the place of assistant master. He finished his studies in 1763, and the fame of an intermezzo which he then composed, obtained for him an immediate engagement to write two operas for Bologna. The success of these was so great that his reputation at once spread through all Italy. In 1777 he was, at the same moment, offered engagements at Vienna, at London, and at St Petersburg. In June 1777 his opera *Dal finto al vero* was represented at Naples; and on the 25th of July following he set out for Russia. He resided eight years at St Petersburg, where he received a large salary, and composed some of his finest works; among others, his opera *Il Barbiere di Seviglia*. On his way back to Italy, he stopped at Vienna, and composed there twelve symphonies for a large orchestra, and the opera-buffa *Il Re Teodoro*, which contains a septuor that became celebrated throughout Europe. During his stay at St Petersburg, Paisiello had made some changes in his style of composition; and at Rome, in 1785, when he brought out his opera *L'Amor ingegnoso*, he found that his countrymen loudly disapproved of these changes. He then settled at Naples, where he had no rival, Guglielmi and Cimarosa being absent. For the next thirteen years he composed for the Neapolitan theatres, and produced, during that time, some of his best operas. Ferdinand IV. appointed him his chapel-master, with a salary of twelve hundred ducats per annum. In 1788 the King of Prussia invited Paisiello to visit Berlin; but this invitation was declined, as well as a second one to St Petersburg, and a first one to London. In 1797 General Bonaparte opened to competitors the composition of a funeral march in honour of General Hoche. Paisiello and Cherubini each sent a march; and Bonaparte, very unjustly, decided in favour of Paisiello. In consequence of the revolution at Naples in 1799, and of his own political tergiversation, Paisiello lost his royal appointments for two years. Soon after their being restored, Bonaparte, then First Consul, requested the King of Naples to send Paisiello to Paris, in order to direct the consular chapel; and he was accordingly sent thither in September 1802. His treatment by Bonaparte was munificent, while Cherubini was quite neglected. (See the article CHERUBINI.) The opera of *Proserpine*, composed by Paisiello in 1803, was ill received by the Parisians; and this check, and his failing imagination, induced him to request leave to retire, under pretext of his wife's ill health. Bonaparte unwillingly granted the request, and Paisiello returned to Naples and to his former service. Afterwards, under Joseph Bonaparte and Murat, Paisiello retained his appointments until a new revolution reduced him to indigence. He died on the 5th of June, 1816, aged seventy-five years. He was a member of the French Institute, and of the Royal Society of Arts and Sciences at Naples, and was president of the directors of the new Neapolitan Conservatory of Music. It appears that he was excessively jealous of all musical rivals, and that he used unworthy means of intrigue to injure Guglielmi and Cimarosa, and also Rossini, when the latter began his brilliant career. The charm of Paisiello's style consists in sweet and graceful melody, and great simplicity of structure. His compositions were very numerous. He himself believed them to amount to two hundred. In published lists of his works we find ninety operas and four cantatas; an oratorio (*La Passione*), and eighteen masses, requiems, &c.; eighteen instrumental quartets; two volumes of harpsichord sonatas, &c.; six pianoforte concertos; funeral march for General Hoche; a collection of figured basses for the study of accompaniment. (G. F. G.)

PAISLEY, the principal town of Renfrewshire, Scotland, is finely situated on the banks of the White Cart, about 3 miles S. of the River Clyde. The ancient and principal part of the town occupies the summit and slopes of a beautiful declivity, the eastern base of which is washed by the

[1] Dr Burney, in his *Tour* and *History*, Signor Perotti, in his *Dissertazione*, and some other writers, spell the name "Paesiello."

river, which divides the burgh into two parts, that on the east side being styled the New Town, from its more recent erection. Paisley is generally considered as the ancient *Vanduara* of Ptolemy, and as having been a Roman town or station during the presence of these invaders in the northern part of Scotland. As late as the beginning of the last century, considerable vestiges remained of a Roman camp on the western side of the hill on which Paisley is built; but these have long since been obliterated by the progressive extension and improvement of the town. The latitude of Paisley is 55. 51. N., and the longitude 4. 26. W. The climate is temperate, but humid. In former times infectious diseases were of rather frequent occurrence. In 1645 a pestilence committed great ravages in this place; and in 1765 dysentery prevailed to an alarming extent. In 1771 pleurisy carried off numbers of the inhabitants; and virulent influenza has visited it at various times. Paisley, however, has never been considered unhealthy; and the registrar-general's returns for the years 1855, 1856, and 1857, show, that in regard to mortality it occupies a medium position among the large towns of Scotland. During these years the rate of mortality in Paisley has not been so high as in Greenock or Glasgow; it has been very nearly the same as in Dundee, and it has been higher than in Aberdeen or Edinburgh.

Whether the Roman town or station called Vanduara was a place of any size or importance is unknown. A cloud overhangs the history of Paisley till about the year 1163, when Walter, the first Stewart, founded a monastery on the eastern bank of the Cart, opposite to what is now termed the Old Town of Paisley. At this period there does not appear to have been a village or hamlet, however small, in existence; but the protection which the monastery afforded in those rude times, and the multitude of pilgrims, travellers, and persons of distinction who frequented it, gradually induced a population to assemble in its vicinity; and a village of some extent made its appearance on the western bank of the river, and began slowly to clamber up the gentle slope of the hill on that side. In 1220 the monastery was elevated to the dignity of an abbey, and many valuable privileges were subsequently conferred upon it by the Pope, and by its founder and successive patrons. Its jurisdiction and revenues were very extensive, extending to, and being derived from, localities at a great distance; its abbots were commonly men of the highest family connections, and appear frequently as prominent actors on the stage of Scottish civil and ecclesiastical history. After the Reformation, the revenues and privileges of this ecclesiastical establishment were bestowed upon Lord Claud Hamilton, and have since become the property, though greatly reduced, of the noble family of Abercorn. A considerable part of the ancient abbey still remains, and is in excellent preservation. The skeleton of a beautiful window, 35 feet in height by 18 in breadth, almost the only fragment of the more ancient part of the building, has been much admired for its size, lightness, and fine proportions. The external architecture of the remaining portion is perhaps scarcely equal to that of some other ecclesiastical edifices in Scotland; but the appearance of the nave, which is occupied as a parish church, is grand and striking in no ordinary degree; and some few fragmentary remains of the old monastery exhibit fine specimens of the purest Gothic. Before the accession of the Stuart family to the throne of Scotland, their burying-place was in the abbey; and even after that event two of its members were interred there, viz., the queen of Robert II., in 1387, and Robert III., in 1406. The tomb of Marjory Bruce, daughter of Robert I., is still to be seen in the famous sounding aisle, now occupied as a burial-vault by the Abercorn family.

Notwithstanding the wealth and manufacturing importance of Paisley, it is only a burgh of barony; but its privileges are so very considerable as almost to equal those of a royal burgh. Previously to 1770 the burgh had a voice in the election of a member of Parliament for the county. Now, by the Scottish Reform Act, Paisley sends a member to represent it in Parliament. The constituency in 1857 was 1349. Formerly the government of the town was vested in a provost, three bailies, and seventeen councillors; but by the Scottish Burgh Reform Act there are now a provost, four bailies, a treasurer, and ten councillors.

In 1553 John Hamilton, the last abbot, conveyed by a deed the revenues and privileges of the abbacy to Lord Claud Hamilton, then a child of ten years of age. He was afterwards deprived of the latter on account of his adherence to the fortunes of Queen Mary; but in 1591 they were restored, with the title of Lord Paisley. In 1653 the second Earl of Abercorn disposed of his interest in the abbacy to the Dundonald family; and in 1658 the magistrates and council purchased this superiority. Since that time Paisley has held directly of the crown. In 1857 the real annual rent of all the property within the burgh was L.99,628.

The topography of Paisley and its vicinity is not very remarkable. Previously to the year 1736 the whole of this district was included in one parish, known by the name of the parish of Paisley; but since that time the burgh has been divided into three parishes—the High, the Middle, and the Low. The Abbey parish now comprehends the New Town, which, with a trifling exception, is separated from the burgh by the River Cart, and the populous villages of Johnstone, Elderslie, Thorn, Quarrelton, Nitshill, Hurlet, and Dovecot Hall, with the country districts. To the north, and affording a noble view from the eminence on which Old Paisley is chiefly built, extends the great plain of the lower valley of the Clyde, anciently called *Strathgryffe*. On the south the Gleniffer, or Paisley Braes, distant about 3 miles, swell gently up to the height of 760 feet above the surface of the Cart. The soil is of a mixed character, but in many places rich and fertile. From the heights just mentioned descend a variety of minor streams, of great utility to the agriculturist and manufacturer, and adding to the richness and beauty of the scenery. The surface of the country in the neighbourhood, with the exception of that to the north, which is flat, is agreeably diversified, and broken into gentle swells and soft declivities, which, with the mixture of gentlemen's seats, farm-houses, bleaching-fields, and other public works, confers a picturesque and animated character upon the entire vicinage. Valuable minerals abound in the parish, such as coal, limestone of the coal formation, and ironstone. In the strath to the north-west of the town, extending towards Linwood, valuable blackband ironstone has recently been discovered, and is now being extensively worked by Messrs Merry and Cunningham, and others. A great mining population is rapidly collecting in that district. There are also very extensive coal-pits wrought in the neighbourhood, chiefly at Johnstone; and in that vicinity, and at Hurlet, the chemical works of the Messrs Wilson and others are on a very large scale. Very fine freestone is also obtained in the neighbourhood.

As it is chiefly, however, to its being one of the principal manufacturing stations in the kingdom that Paisley owes its celebrity, we shall now present a brief sketch of the history, progressive improvement and increase, and present extent of its principal manufactures. There is no certain account as to the precise period when the art of weaving was introduced. It appears, however, that the manufacture of linen was carried on to a considerable extent during the last century. Shortly after the Union the spirit of manufacturing enterprise sprang up in the west of Scotland, and Paisley was not slow in availing itself of the general impulse. Craufurd, describing the state of Paisley in 1710,

Paisley. observes:—"That which renders this place considerable is its trade of linen and muslin, where there is a great weekly sale in its markets of those sorts of cloth, many of the inhabitants being chiefly employed in that sort of manufactory." From 1744 to 1784 the linen manufacture increased in amount from L.18,886, 15s. 10d. to no less than L.184,385, 16s. 6½d. About the year 1722 the manufacture of linen thread was introduced into Paisley, and carried on to a large extent. For several years it reached the amount of L.100,000 annually. Cotton thread, having superseded that made from linen yarn, is manufactured to a very considerable extent, and forms one of the principal manufactures of the place. Besides the establishment of the Messrs Coats, which is said to be the most extensive, the most valuable, and the most magnificent of the kind in the world, there are now about ten others, some of which are very extensive. The value of the thread annually manufactured in Paisley at the beginning of the present century was estimated at L.60,000. It is now about L.400,000. In 1760 silk gauze began to be manufactured in Paisley; and in a short time the skill and ability with which this manufacture was prosecuted caused its abandonment by the manufacturers of Spittalfields, the original seat of the silk manufacture in Great Britain. This manufacture flourished extensively until near the close of the last century. From 1772 there existed also a considerable manufacture of ribbons and other articles in silk. In 1744 the value of the manufactures of Paisley was L.579,185, and in 1769 it amounted to L.660,385. In 1744 only 867 looms were employed in the weaving of linen; and forty years afterwards no fewer than 5000 looms were engaged in the manufacture of silk, the produce of which amounted to L.350,000.

Towards the end of last century the making of silk goods declined rapidly; but a new species of manufacture sprang up, which has since been carried to a much greater extent. The manufacture of shawls, of cotton, silk, and fancy woollen fabrics, has now become the staple trade of Paisley. In little more than forty years after its introduction (in 1834) this manufacture produced about a million sterling; and since then it has increased considerably.

Previously to the present century fine shawls had been manufactured in this country chiefly at Norwich and Stockport in England, where they were made in imitation of the rich India shawls. The latter, from their high price, were beyond the reach of all but a few wealthy individuals, when the manufacturing skill and enterprise of Paisley embarked in the manufacture, and, by successive inventions and improvements in the loom, and in the kind and quality of the materials, prosecuted for a long series of years, succeeded in realizing a nearly perfect imitation of those oriental fabrics in colours, texture, and design, and at a mere fraction of the cost. Besides the extraordinary cheapness, the variety of new and beautiful fabrics and designs which have been introduced into the shawl manufacture have largely contributed to its extent and success. The manufacture of shawls is almost wholly confined to Paisley; but a considerable proportion of these find their way to the Glasgow markets for home and foreign sale. The kinds produced are various in quality and cost, and there is a great variety in the styles and fabrics. Some are wholly made of silk, but these are not now much in demand; others of silk and cotton, and a great many of Persian and fancy wools mixed with both or either. Thibet cloth shawls, a very rich and fanciful fabric; Chenille shawls, a beautiful imitation of silk velvet; Canton crape shawls; and various other and newer kinds, of every possible variety in size, texture, pattern, and price, are produced from the looms of Paisley, with a rapidity and abundance which, whilst it tends occasionally to overload the market, affords satisfactory evidence of the manufacturing skill and resources of Paisley. The present annual amount of the trade and manufactures of Paisley has been roughly calculated at nearly two millions sterling. To give anything like a view of the various inventions and improvements in the art of weaving, by means of which Paisley has attained its present eminence as a chief seat of the silk and cotton manufactures in Scotland, would swell this article beyond all due bounds. The hasty sketch which we have supplied affords some general data to the reader, who may consult, if he wishes for more minute information, Wilson's *Survey of Renfrewshire;* Craufurd's *Description of the Shire of Renfrew*, with Robertson's continuation; and the *New Statistical Account of Scotland.* The spinning of cotton yarn is also extensively carried on by Paisley manufacturers in the town and parish, but there are no data to be relied on for ascertaining its annual amount. Bleaching and dyeing, as might be expected, are prosecuted to a very considerable extent. Soap-making is a trade of some antiquity and importance; and malting, the distillation of raw spirits, and silk-throwing, have also a considerable capital embarked in them. Owing to the frequent and severe depressions that have recently occurred in connection with the weaving trade of Paisley, a considerable number of those formerly engaged in that line have transferred their industry to other employments. By this means some branches of business, formerly existing in the town, have been very much extended, and others entirely new have been introduced. Among the branches thus increased or introduced, the principal are the thread manufacture already mentioned, shawl-printing, soap-making, iron-founding, engineering, and iron ship-building.

Thursday is the market-day in Paisley, and there are four fairs annually, which last three days each. The races at St James' Day Fair were long well known in the west of Scotland, and attracted great numbers from the surrounding districts. For many years they were much frequented by the sporting world; but after the close of the races, on the last day of the sport in August 1857, a serious and disgraceful riot occurred on the course. A number of the inhabitants memorialized the burgh trustees, and the provost and magistrates, against the continuance of the races. After several meetings, the burgh trustees and the town council agreed to discontinue the races. The grounds, including the course, were let for agricultural purposes; and the Paisley race-course, one of the best in the kingdom, is now a ploughed field.

Paisley is abundantly supplied with the means of external communication. The Glasgow and Greenock, and the Glasgow and South-Western railways, both pass through it. There is a railway to the Clyde near Renfrew; and although the Glasgow, Paisley, and Johnstone Canal has ceased to carry passengers, it is still available, and largely used, for the conveyance of goods.

The yearly returns of the post-office show the growing prosperity of Paisley. In 1720 the amount was only L.28, 13s.; 1769, L.223, 3s. 8d.; 1809, L.2814, 17s. 4d.; 1834, L.3194. Since the introduction of the penny postage, the delivery of letters from the Paisley post-office has risen to about 676,000 in a year. In the money-order department there are about 14,000 transactions in a year.

The river Cart is navigable to Paisley for vessels of from 60 to 80 tons burthen. The river dues in 1835 amounted to L.260, and at the present time they are about L.600.

Paisley is well supplied with the means of religious instruction. There are 8 congregations in connection with the Church of Scotland, 6 with the Free Church, 6 with the United Presbyterian Church, and about 16 of various other denominations. There is, therefore, on an average, one congregation for every 1350 of the burghal population. The number of scholars attending the different sabbath schools in Paisley during the year 1857 amounted to 6614.

The grammar school of Paisley was established by King James VI. The charter of erection is dated "at Halierude House," 3d January 1576, but the oldest date on the tablet in front of the building is 1586. Besides the grammar school, there are three other burgh schools, and a number of private or adventure schools. Within the last few years large sums have become available for the education of the poor. The late John Neilson bequeathed a sum for this purpose, which is supposed to have accumulated to about L.30,000. He died in 1839; and the school was opened in 1852. Other sums of smaller amount have been bequeathed for similar purposes. At present, active preparations are being made for opening an institution for reclaiming youthful offenders. The late Miss Kibble, some years ago, bequeathed for that purpose a sum now amounting to L.10,000. The Educational Association supports several schools which supply education to a great number of pupils at a very cheap rate; and the Ragged School furnishes a home and education to the houseless and the destitute. Hutcheson's Charity, though possessed of very scanty means, gives gratuitous education to a large number of children; the General Session educates gratuitously 100 pupils; and several of the congregations support schools in which education is given either gratuitously or at nominal fees, in some cases as low as one penny a week. In addition to all this, the Committee of Privy Council on Education have at different times granted considerable sums to assist in building schoolhouses; and large sums are annually received from the same source to supplement teachers' salaries, and to pay for pupil teachers for the education of the poor. The amount received in Paisley in 1857 for these purposes, together with the sum required for reducing the price of schoolbooks, could scarcely be less than L.1000. In future years this sum will be very considerably increased.

The town is well lighted with gas, and there is an abundant supply of excellent water, collected from the neighbouring heights in two large reservoirs, from which it is conveyed into the town by gravitation. The assessment for the poor in the three town parishes for the year ending May 1858 was L.5200; and in the Abbey parish for the same year the assessment was L.5000.

There are few public buildings of importance in Paisley. Besides the Abbey, may be mentioned St George's parish church, the Free High church, the Episcopal church, and also the Oakshaw Street and Abbey Close United Presbyterian churches. The county buildings are of considerable extent and elegance, in the castellated style; and the newsroom at the Cross is also a handsome building. The John Neilson Institution is in itself a very fine building, and occupying, as it does, by far the best situation in Paisley, it appears to great advantage. There are three bridges over the Cart, connecting the Old and the New Town of Paisley, but none of them is remarkable. The most important public charity in Paisley is the infirmary, supported by voluntary subscriptions.

The civil history of Paisley affords little to interest or deserve the attention of the general reader. Its ecclesiastical history is curious and interesting, but supplies few points sufficiently salient and compact to be entered upon in so brief a sketch. The famous "Black Book of Paisley," which was long supposed to have been a history of Paisley and its monastery, has been ascertained to be the *Scotichronicon* of Fordun, a monk of the fourteenth century. The inhabitants of Paisley early embraced the doctrines of the Reformation, notwithstanding the naturally adverse influences of the great monastic establishment; and displayed their attachment to these on various occasions during the civil wars and prelatical persecutions of the seventeenth century. In 1715 and 1745 they showed equal zeal for the House of Brunswick; and the burgh had to pay a fine of L.500 to the Young Chevalier at the latter period, as a composition for its anti-Jacobite predilections. The magistrates afterwards memorialized government for compensation, but they never obtained it. In 1597 the queen of James VI. honoured the inhabitants with a visit to their town, when it would appear that the royal entertainment fell so heavy on the burgh funds, that in 1617, when her royal consort also visited it, the civic dignitaries prudently forbore so costly a welcome, but in lieu thereof employed "a prettie boy, a son of a Sir James Semple of Beltrees," to make him a speech, which was judiciously spiced for James's royal ear.

In 1695 the population of the town of Paisley, exclusively of the Abbey parish, where there were then very few houses, was only 2200. In 1755, sixty years after, it amounted in the town and Abbey parish to 6799; and in 1781 to 11,100 in the town alone, the population of the Abbey parish not being given in the register. In 1791 the total population was 24,592; 1801, 31,179; 1811, 36,722; 1821, 47,003; 1831, 57,466; 1841, 60,487; 1851, 60,332. In 1851 the population of the parliamentary burgh was 48,026; and in 1858 the same was estimated at 48,302.

PAJOU, Augustin, an eminent French sculptor, was born at Paris in 1730, and studied in the workshop of Lemoine. His talents and facile skill were soon recognised, and his career of distinction began early. At the age of eighteen he gained the French Academy's grand prize for sculpture, and the attendant privilege of being sent to Rome to complete his studies. On his return at the end of twelve years, he immediately assumed a high place in his profession. He was elected forthwith a member, and in 1767 a professor, of the Academy. Louis XVI. also employed him to adorn with sculptures the façade of the Palais Royal, and to execute statues of Pascal, Turenne, Bossuet, Buffon, and Descartes. From these and his numerous other works Pajou had realized a handsome competency; but the Revolution deprived him of it, and left him for the rest of his days in comparative poverty. His death took place in 1809.

PAK PATTAN, or the *Pure Town*, a town of India, in the Punjab, stands on a mound 40 feet high, in the midst of a plain, 5 miles W. of the Ravee, and 98 S.S.W. of Lahore. It derives its name from having been long the residence of a famous Mohammedan saint, whose tomb, a plain edifice in a depression below the general level of the town, is much frequented by pilgrims, both Hindu and Mohammedan. Pak Pattan is believed to be the site of the colossal altars erected by Alexander the Great to mark the limits of his conquests.

PAKS, a town of Hungary, county of Tolna, stands on the right bank of the Danube, 62 miles S. of Buda. The inhabitants are chiefly employed in the culture of the vine, and in sturgeon-fishing. There are two churches and a synagogue, a cattle market, and it has some trade in corn. Pop. (1846) 7310.

PALÆOGRAPHY (πάλαιος, *ancient*, and γράφω, *I write*), is that branch of knowledge which has to do with the interpretation of ancient inscriptions and documents. (See Archæology, Diplomatics, Hieroglyphics, and Egypt. For an account of the catalogues of manuscripts in the British Museum and elsewhere, see Libraries.)

PALÆOLOGUS, the name of an illustrious Byzantine family, first mentioned in history in the eleventh century, from which period it played an important part in the affairs of the empire till its downfall. The family of Palæologus occupied the throne of Constantinople without interruption from 1260 to 1453, when that city was taken by the Turks. (See Constantinopolitan History. A full account of this powerful house will be found in the *Familiæ Byzantinæ* of Ducange, pp. 230-348; and a stemma of the family is given under "Paläologen," in Ersch and Gruber's *Encyclopadie;* also in Smith's *Dictionary of Greek and Roman Biography and Mythology*.)

PALÆONTOLOGY[1]

Introduction. **Definition.** Is the science which treats of the evidences of organic beings in the earth's strata; evidences mainly consisting of petrified or fossil remains of plants and animals belonging to species that are mostly extinct.

Application to comparative anatomy, The endeavour to interpret such evidences has led to comparisons of the forms and structures of existing plants and animals, which have greatly and rapidly advanced the science of comparative anatomy, especially as applied to the animal kingdom, and herein more especially to the hard and enduring parts of the animal frame, such as corals, shells, crusts, scales, bones, and teeth.

physiology, In applying the results of these comparisons to the restoration of extinct species, physiology has benefited by the study of the relations of structure to function requisite to obtain an idea of the food and habits of such species. It has thus been enriched by the well-defined law of "correlation of structures."

zoology, Zoology has gained an immense accession of subjects through the determination of the nature and affinities of extinct animals, and its best aims have been proportionally advanced. Much further and truer insight has been gained into the natural arrangement and subdivision of the classes of animals since palæontology expanded our survey of them. Thus a few hard-scaled fishes,—*Polypterus, Lepidosteus, e.g.*,—which represent a subordinate group of the herring family (*Clupeidæ*), in the second edition of Cuvier's *Règne Animal*, have been found to be the remnants of an almost extinct order, equivalent to the whole *Malacopterygii* of that naturalist; and the *Ruminantia*, which Cuvier deemed to be a very natural and well-defined order, has since become known to be a peculiarly modified subdivision of a wider and more natural group of hoofed quadrupeds, the *Artiodactyla*.

homology, The knowledge of the type or fundamental pattern of certain systems of organs, *e.g.*, the framework of the Vertebrata and the teeth of the Mammalia, has been much advanced by the more frequent and closer adherence to such type discovered in extinct animals, and thus the highest aim of the zoologist has been greatly promoted by palæontology.

geology, But no collateral science has profited so much by palæontology as that which teaches the structure and mode of formation of the earth's crust, with the relative position, time, and order of formation of its constituent stratified and unstratified parts. Geology has left her old hand-maiden mineralogy, to rest almost wholly upon the broad shoulders of her young and vigorous offspring, the science of organic remains.

geography, By this science the law of the geographical distribution of animals, as deduced from existing species, is shown to have been in force during periods of time long antecedent to human history, or to any evidence of human existence; and yet, in relation to the whole known period of life-phenomena upon this planet, to have been a comparatively recent result of geological forces determining the present configuration and position of continents. In this relation, palæontology throws light upon a most interesting branch of geographical science, that, viz., which relates to former configurations of the earth's surface, and to other dispositions of land and sea than prevail at the present day.

and philosophy. Finally, palæontology has yielded the most important facts to the highest range of knowledge to which the human intellect aspires. It teaches that the globe allotted to man has revolved in its orbit through a period of time so vast that the mind, in the endeavour to realize it, is strained by an effort like that by which it strives to conceive the space dividing the solar system from the most distant nebulæ.

Introduction. Palæontology has shown that, from the inconceivably remote period of the deposition of the Cambrian rocks, the earth has been vivified by the sun's light and heat, has been fertilized by refreshing showers, and washed by tidal waves; that the ocean not only moved in orderly oscillations regulated, as now, by sun and moon, but was rippled and agitated by winds and storms; that the atmosphere, besides these movements, was healthily influenced by clouds and vapours, rising, condensing, and falling in ceaseless circulation. With these conditions of life, palæontology demonstrates that life has been enjoyed during the same countless thousands of years; and that with life, from the beginning, there has been death. The earliest testimony of the living thing, whether coral, crust, or shell, in the oldest fossiliferous rock, is at the same time proof that it died. At no period does it appear that the gift of life has been monopolized by contemporary individuals through a stagnant sameness of untold time, but it has been handed down from generation to generation, and successively enjoyed by the countless thousands that constitute the species. Palæontology further teaches, that not only the individual, but the species perishes; that as death is balanced by generation, so extinction has been concomitant with the creative power which has continued to provide a succession of species; and furthermore, that, as regards the various forms of life which this planet has supported, there has been "an advance and progress in the main." Thus we learn, that the creative force has not deserted the earth during any of the epochs of geological time that have succeeded to the first manifestation of such force; and that, in respect to no one class of animals, has the operation of creative force been limited to one geological epoch; and perhaps the most important and significant result of palæontological research has been the establishment of the axiom of *the continuous operation of the ordained becoming of living things*.

In entering upon the present survey of the evidences of organic beings in the earth's crust, it is proposed to commence with the lowest or most simple forms, and, as the subject of fossil plants has been ably dealt with under the head PALÆONTOLOGICAL BOTANY, in vol. v., p. 232, to treat chiefly of the remains of the animal kingdom.

A reference to the subjoined "Table of Strata" (fig. 1) will indicate the relative position of the geological formations cited. The numerals opposite the right hand give the approximative depth or vertical thickness of the strata.

Definition of organisms; of animals, of plants. Organisms, or living things, are those which possess such an internal cellular or cellulo-vascular structure as can receive fluid matter from without, alter its nature, and add it to the alterative structure. Such fluid matter is called "nutritive," and the actions which make it so are called "assimilation" and "intus-susception." These actions are called "vital," because, as long as they are continued, the "organism" is said "to live." When the organism can also move, receive the nutritive matter by a mouth into a stomach, inhale oxygen and exhale carbonic acid, develop tissues the proximate principles of which are quaternary compounds of carbon, hydrogen, oxygen, and nitrogen, it is called an "animal." When the organism is rooted, has no mouth or stomach, exhales oxygen, has tissues composed of "cellulose" or of binary or ternary compounds, it is

Introduction.

Table of Strata and Order of Appearance of Animal Life upon the Earth.

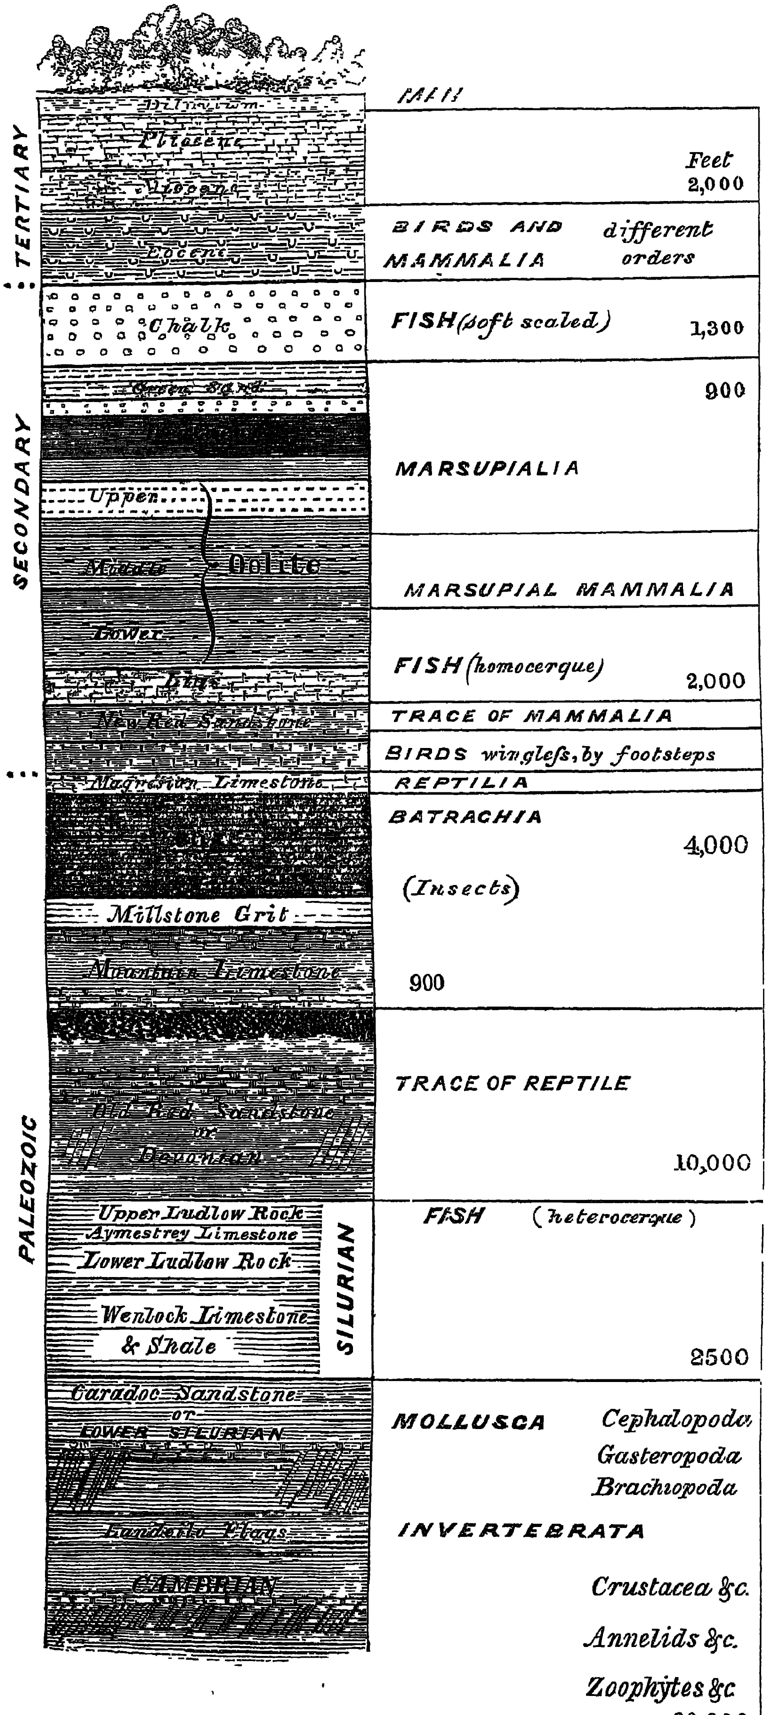

Fig. 1.

called a "plant." But the two divisions of organisms called "plants" and "animals" are specialized members of the great natural group of living things; and there are numerous organisms, mostly of minute size and retaining the form of nucleated cells, which manifest the common organic characters, but without the distinctive superadditions of true plants or animals. Such organisms are called "Protozoa," and include the sponges or *Amorphozoa*, the *Foraminifera* or Rhizopods, the *Polycystineæ*, the *Diatomaceæ*, *Desmidiæ*, and most of the so-called *Polygastria* of Ehrenberg, or infusorial animalcules of older authors.

Protozoa.

PROTOZOA.

Class I.—AMORPHOZOA.

Fossil sponges take an important place among the organic remains of the former world, not only on account of their great variety of form and structure, but still more because of the extraordinary abundance of individuals in certain strata. In England they specially characterize the chalk formation,—extensive beds of silicified sponges occur in the upper greensand, and in some beds of the oolite and carboniferous limestone. In Germany a member of the Oxford oolite is called the "spongitenkalk," from its numerous fossils of the present class.

Existing sponges are divided into *horny*, *flinty*, and *limy*, or "ceratose," "silicious," and "calcareous," according to the substance of their hard sustaining parts, which parts are commonly in the shape of fine needles, or *spicula*, of very varied forms, but in many species of sufficient constancy to characterize such species. The soft organic substance is for the most part structureless and diffluent; it is uncontractile and impassive. The larger orifices on the surface of a sponge are termed "oscula," and are those out of which the currents of water flow; these enter by more numerous and minute "pores."

The calcareous sponges abound in the oolitic and cretaceous strata, attaining their maximum of development in the chalk; they are now almost extinct, or are represented by other families with calcareous spicula. The horny sponges appear to be more abundant now than in the ancient seas, but their remains are only recognisable in those instances where they were charged with silicious spicula.

M. D'Orbigny enumerates 36 genera and 427 species of fossil sponges; and this is probably only a small proportion of the actual number in museums, as the difficulty of determining the limits of the species is very great, and many remain undescribed.

Palæospongia and *Acanthospongia* occur in the lower Silurian; and *Stromatopora*, with its concentrically laminated masses, attains a large size in the Wenlock limestone. *Steganodictyum*, *Sparsispongia*, and species of *Scyphia*, are found

in the Devonian; and *Bothroconis*, *Mamillopora*, and *Tragos*, in the Permian or magnesian limestone. Several

4. Manon osculiferum, Phil., *U. Chalk*, Yorkshire.
5. Fusulina cylindrica, Fisch.; *Carboniferous*, Russia.
6. Flabellina rugosa, D'Orb; *Chalk*, Europe.
7 Lituola nautiloidea, Lam; *Chalk*, Europe.
8. Nummulites nummularia, Brug.; *Eocene*, Old World.
9. Orbitoides media, D'Arch.; *U. Chalk*, France.
10. Ovulites margaritula, Lam.; *Chalk*, Europe.

genera are common to the trias and oolites; and several more are peculiar to the latter strata. The Oxfordian sponges belong chiefly to the genera *Eudea*, *Hippalimus*, *Cribrispongia*, *Stellispongia*, and *Cupulispongia*. Their fibrous skeleton appears to have been entirely calcareous, and often very solid; their form is cup-shaped, or mammillated, or incrusting; and many have a sieve-like appearance, from the regular distribution of the excurrent orifices (*oscula*) over their surface.

The greensand of Faringdon in Berkshire is a stratum prolific in sponges, chiefly cup-shaped and calcareous, of the genera *Scyphia* and *Chenendopora;* or mammillated, like *Cnemidium* and *Verticillopora*. The Kentish rag is full of sponges, which are most apparent on the water-worn sides of fissures. Some beds are so full of silicious spicula as to irritate the hands of the quarrymen working those beds. The greensand of Blackdown is famous for the number and perfect preservation of its pear-shaped *Siphoniæ* (fig. 2, 1); whilst those of Warminster are ornamented with three or more lobes. The latter locality is the richest in England for large cup-shaped and branching sponges (*Polypothecia*), which are all silicified. The sponges, chiefly *Siphoniæ*, of the upper greensand of Farnham are infiltrated with phosphate of lime, and have been used in agriculture.

The sponges of the chalk belong to several distinct families. *Choanites* resembles the *Siphonia*, but is sessile, and exhibits in section, or in weathered specimens, a spiral tube winding round the central cavity. It is the commonest sponge in the Brighton brooch-pebbles. Others are irregularly cup-shaped and calcareous; and many of the Wiltshire flints have a nucleus of branching sponge (*S. clavellata*). The chalk flints, arranged in regular layers, or built up in columns of "Paramoudræ," all contain traces of sponge structure, and their origin is in some measure connected with the periodic growth of large crops of sponges. Frequently the crust or outer surface only of the sponge has been silicified, while the centre has decayed, leaving a botryoidal or stalactitic cavity. The cup-shaped sponges are almost always more or less enveloped with flint, which invests the stem and lines the interior, leaving the rim exposed. The sponges of the Yorkshire chalk are of a different character: some are elongated and radiciform, others horizontally expanded, but they contain comparatively little silica; while those belonging to the genus *Manon* (fig. 2, 4), having prominent "oscula," are superficially silicified, and will bear immersion and cleaning with hydrochloric acid. The largest group of chalk sponges, typified by *Ventriculites* (fig. 2, 3), have the form of a cup or funnel, slender or expanded, or folded into star-like shape (*Guettardia*, fig. 2, 2), with processes from the angles to give them firmer attachment. Some have a tortuous or labyrinthic outline, and others are branched or compound, like *Brachiolites*. Curious sections of these may be obtained from specimens enveloped with flint or pyrites. The burrowing-sponge, *Cliona*, is commonly found in shells of the tertiaries and chalk. The great cretaceous *Exogyræ* of the United States are frequently mined by them; and flint casts of *Belemnites* and *Inocerami* are often covered by their ramifying cells and fibres. Thin sections of chalk flints, when polished and examined with the microscope, sometimes exhibit minute spherical bodies (*Spiniferites*) covered with radiating and multicuspid spines. From their close resemblance to the little fresh-water organism *Xanthidium*, they long bore that name; but they are certainly marine bodies, and probably the spores of sponges.

Class II.—Foraminifera.

The organisms of this class are small, and for the most part of microscopic minuteness,—of a simple gelatinous structure, protected by a shell. They grow by successive gemmation from a primordial segment, sometimes in a straight line, more commonly in a spiral curve; and each segment so developed has its own shelly envelope. As, however, they are organically connected, the whole seems to form a "chambered" or "polythalamous" shell. The last-formed segment is usually distinguished by very long, slender, pellucid, colourless, contractile filaments, like rootlets; whence the name "Rhizopods," sometimes given to the class. But both the outer wall and the septa of the compound shell are perforated by minute apertures, through which either connecting or projecting filaments of the soft organic tissue pass; whence the name *Foraminifera*. The several segments or jelly-filled chambers are essentially repetitions of each other; and there is no proof that the inner and earlier segments derive their nourishment from the outer and last-formed one. A Foraminifer may therefore be regarded either as a series of individuals, organically united, or as a single aggregate being, compounded according to the law of vegetative repetition.

The minute, chambered shells of Rhizopods enter largely into the composition of all the sedimentary strata, and are so abundant in many common and familiar materials, like the chalk, as to justify the expression of Buffon, that the very dust had been alive. The deep-sea soundings of the Atlantic Telegraph Company have shown that the bed of that great ocean, at a depth approaching, or even exceeding, two miles, is composed of little else than the calcareous shells of a *Globigerina* and a few other Rhizopods, with the silicious shields of the allied *Polycystineæ*. The composition of the chalk is extremely similar: when the finer portion, amounting to half or even less, has been washed away, the remaining sediment consists almost entirely of foraminated shells, some perfect, others in various stages of disintegration. They have also been found in other marine formations which are soft enough to be washed, down to the Lower Silurian; and in the hard limestones and marbles they can be detected in polished sections, and thin slices laid on glass. The greater part of these shells are microscopic, but some of the large extinct Foraminifera, called, from resembling a piece of money, Nummulites, are two inches in diameter. The generic divisions in use for these shells were mostly invented by M. D'Orbigny, but on artificial grounds,—viz., exclusively upon the plan of growth, or

Protozoa.

mode of increase in the number of chambers. The structure and anamorphoses of these complex atoms have been recently investigated by Messrs Williamson and Carpenter, and especially by Mr W. K. Parker. Six hundred and fifty-seven fossil species, belonging to seventy-three genera, are described,—commencing in the palæozoic age, increasing in number and variety with each successive stratum, and attaining their maximum in the present seas. Most of these genera, and even some of the species, pass through many formations; indeed, if correctly observed, they are the oldest known living organisms. *Dentalina communis*, *Orbitolites complanatus*, *Rosalina italica*, and *Rotalina globulosa*, all living species, are said to be found in the chalk; *Rotalina umbilicata* ranges to the gault; and *Webbina rugosa* is common to the upper lias, the chalk, and present sea. It has, however, been observed that fossil Rhizopods, set free by the disintegration of rocks, are mingled with the recent shells on every beach; and Mr M'Andrew has obtained them in this condition from great depths of the mid-channel.

The earliest important form is the *Fusulina* (fig. 2, 5), which forms layers many inches, or even feet, in thickness in the carboniferous limestone of Russia. The recent genera *Dentalina* and *Textularia* are found in the magnesian limestone; *Nodosaria*, *Cristellaria*, and *Rotalia*, in the lias. *Flabellina* (fig. 2, 6) is peculiar to the chalk; *Orbitoides* (fig. 2, 9) to the chalk and tertiary series; *Ovulites* (fig. 2, 10) is peculiar to the eocene tertiaries; *Operculina*, *Orbitolites*, and *Alveolina* appear first in the tertiary, and are still living. The *Lituola* (fig. 2, 7) occurs in the chalk and in chalk flints, and has been described as a species of "Spirolinite." Many of the cretaceous *Foraminifera* contain a brown colouring matter, which remains after the shell has been dissolved with weak acid, and has been regarded as the remains of the animal substance which once filled all the cells.

The "calcaire grossier," which is employed at Paris as a building-stone, contains *Foraminifera* in such abundance that one may say the capital of France is almost constructed of those minute and complex shells.

But it is in the middle eocene, or "nummulitic period," that the Rhizopods attained their greatest size, and played their most important part. Wherever limestones or calcareous sands of this period are met with, these Foraminifera abound, and literally form strata which in the aggregate become mountain masses. These "nummulitic limestones" are found in Southern Europe, in Northern Africa, and in India; they also occur in Jamaica. The commonest form is the *Nummulite* (fig. 2, 8), which occurs in the building-stone of the Great Pyramid. These *Nummulites* were evidently sedentary; and in the large thin species, one side is moulded to the inequalities of the sea-bed on which it grew.

Polycystineæ.—The tertiary marls of Barbadoes afforded to Ehrenberg an extensive series of novel and extraordinary microscopic organisms, composed of silica, but foraminated like the shells of the Rhizopods. The same forms, and others similar to them, have been met with in the deep-sea mud of the Gulf of the Erebus and Terror, and more recently in the mud of the Atlantic soundings. They are quite distinct in form and character from most of the silicious-shielded *Diatomaceæ*, but some of them resemble the *Coscinodiscus* and *Actinocyclus*. No less than 282 forms, grouped in 44 provisional genera, have been described.

Class III.—INFUSORIA.

(*Polygastria*, Ehrenberg.)

Numerous genera and multitudes of so-called species of free and locomotive microscopic organisms, which, because they do not present the distinctive characters of plants or animals, have been by turns referred to one or other kingdom, possess shells of flint, and consequently enter largely into the domain of fossil evidences of former life. The silicious shells of these infusory organisms present under the microscope the most definite as well as beautiful characters of form and sculpture, which are as recognisable and distinctive as those of the calcareous shells of Mollusca. The plates of the incomparable works and memoirs of Ehrenberg abound with exact figures of the delicate sheaths, shells, and shields of the loricated Infusoria of past and present æras of life, the deposits of which, by reason of their pure, flinty, atomic constitution, were known in the arts long before science had detected their nature and vital origin. In 1836 portions of the stone called "tripoli" or "polierschiefer" (polishing-slate of lapidaries) were microscopically examined by Ehrenberg, who discovered it to be wholly composed of the silicious shells of Infusoria, and chiefly of an extinct species called *Gaillonella distans*. At Bilin in Bohemia there is a single stratum of polierschiefer, not less than 14 feet thick, forming the upper layer of a hill, in every cubic inch of which there are forty-one thousand millions of the above-named organic unit. This mineral likewise contains shells of *Navicula*, *Bacillaria*, *Actinocyclus*, and other silicious organisms. The lower part of the stratum consists of the shells compacted together without any visible cement; in the upper masses the shells are cemented together, and filled by amorphous silicious matter formed out of dissolved shells. At Egea in Bohemia there is a stratum of 2 miles in length, and averaging 28 feet in thickness, of which the uppermost 10 feet are composed wholly of the silicious shells of Infusoria, including the beautiful *Campylodiscus*; the remaining 18 feet consist of the shells mixed with a pulverulent substance. Corresponding deposits of the silicious cases of Infusoria have since been discovered in many other parts of the world, some including fresh-water species, others marine species of Infusoria.

The conditions of such depositions will be readily understood by examining the sedimentary deposits of bogs and stagnant or slow-flowing sheets of water. In warm latitudes and seasons, such water swarms with infusorial life, and the indestructible cases of the loricated kinds are found in great quantities in the sedimentary deposits. Beneath peat bogs they have been found to form strata of many feet in thickness, and co-extensive with the turbary, forming a silicious marl of pure whiteness. A quantity of pulverulent matter is deposited upon the shores of the lake near Uranea in Sweden, which, from its extreme fineness, resembles flour: this has long been known to the poorer inhabitants under the name of "berg-mehl," or mountain-meal, and is used by them, mixed up with flour, as an article of food. It consists in great part of silicious shells of Infusoria, with a little organic matter. With regard to the source of fossil infusorial remains in sea-water, the following evidence is given in the *United States Coast Survey*, 1856:—

Soundings of the gulf-stream near Key Siscayne, Florida, varying in depths from 147 fathoms to 205 fathoms, give a light greenish-grey mud composed chiefly of Foraminifers, Diatoms, Polycistins, and Geolites, in a profusion only surpassed by the fossil polycistinous strata of Barbadoes. The Foraminifers compose the largest part of these muds, including *Textularia Americana*, *Marginula Bachei*, and other forms, particularly many species of the *Plicatilia* of Ehrenberg, which had been supposed to live only in shallower haunts. The silicious shells of Diatoms abound in the residue, after the calcareous Foraminifers have been dissolved by acid. The inorganic portion of the soundings is chiefly quartz sand, and its proportion is quite small. Such manifestations of life, with its mineral results, have been detected from the earliest sedimentary deposits to the present time; but as regards the Infusoria, they are given on the grandest scale in formations of the tertiary age.

Animalia.

The town of Richmond in Virginia, United States, is built on barren silicious strata of marine origin and tertiary age. The strata are 20 feet in thickness, composed chiefly of infusorial flint-shells, including the well-known and beautiful microscopic objects, *Actinocyclus* and *Coscinodiscus*.

Most of the infusorial formations, as the polishing-slates at Cassel, Planitz, and Bilin, are astounding monuments of the operation of microscopic organisms at former periods of the history of this planet. The minute size, elementary structure, tenacity of life, and marvellous reproductive power of the Infusoria have enabled them to survive as species those destroying causes which have exterminated contemporaneous higher forms of organism. Species of *Bacillaria* still exist which were in being at the period of the deposition of the chalk. Existing species of *Diatomaceæ* have been detected as low down as the oolite. The discovery by Ehrenberg of more than twenty species of silicious-shelled Infusoria, fossil, in the chalk and chalk-marls, which are identical in species with some now living in the bed of the Baltic, is an instructive addition to the obscure history of the introduction of species of living things in this planet, and must add greatly to the interest of the infusorial class in the eyes of the geologist and philosopher. "For these organisms," writes Ehrenberg, "constitute a chain which, though in the individual link it be microscopic, yet in the mass is a mighty one, connecting the life-phenomena of distant ages of the earth, and proving that the dawn of the organic nature co-existent with us reaches further back in the history of the earth than had hitherto been suspected." "The microscopic organisms are very inferior in individual energy to lions and elephants, but in their united influences they are far more important than all these animals." If it be ever permitted to man to penetrate the mystery which enshrouds the origin of organic force in the wide-spread mud-beds of fresh and salt waters, it will be by experiment and observation on the atoms which manifest the simplest conditions of life.

ANIMALIA.

INVERTEBRATA.

FOSSIL INVERTEBRATA.

Remains of invertebrate animals occur in strata of every age, from the partially metamorphic and crystalline rocks of the Cambrian system to the deposits formed by the floods of the last winter, and the tides of yesterday. They are found in every country, from the highest latitude attained by Arctic voyagers to the extremities of the southern continents, and at the greatest elevation hitherto climbed in the Andes or Himalaya. If some classes,—*e.g.*, *Tunicata*, *Acalephæ*,—seem not to be represented in stratified deposits, they are such as, either from the soluble and perishable tissues composing the entire frame, could not be expected to be fossilized under any conceivable circumstances; or from the same cause, are only not so recognisable at one of their metagenetic phases. Evidence of compound Hydrozoa,—*i.e.*, of the polypes which Ellis called "Corallines,"—and especially of the genus *Campanularia*, would show that the acalephal type and grade of organization had been manifested at the period of the formation of the strata containing such fossil Polypi. With the above seeming exceptions, every class of invertebrate animal is represented by fossil remains.

They consist of corals and shells, of the petrified skeletons of star-fishes and sea-urchins, of the hard coverings of crabs and insects, of the tracks and shelly habitations of worms, and of impressions of surfaces, and casts of cavities of organisms, retained, after these have perished, by the matrix.

Radiata.

The condition in which invertebrate fossils occur depends on the nature of the matrix and other accidental circumstances; for while some are scarcely altered in composition, or even in colour, others are silicified or infiltrated with carbonate of lime. Some may be cleared by the action of acid or exposure to the weather, and some require the chisel of the mason or the mill of the lapidary for the proper exhibition of their structure.

Multitudes of recent species are fossilized in the newer tertiaries whose history can be made out perfectly from living specimens; but the number of these diminishes gradually in each older stratum, while the proportion of extinct forms is ever on the increase. No living species more highly organized than a Rhizopod is found in the secondary rocks. Recent *genera* extend further back in time; indeed a few may be recognised in strata of palæozoic age, shedding a light on the probable affinities and conditions of their associates. Many of the smaller groups of genera, called *families*, disappear in the secondary, and still more in the palæozoic period, and are to a limited extent replaced by groups which no longer exist. But, as to the larger groups of *Protozoa* and true invertebrate animals, it may be affirmed that every known fossil belongs to some one or other of the existing classes, and that the organic remains of the most ancient fossiliferous strata do not indicate or suggest that any earlier and different group of beings remains to be discovered, or has been irretrievably lost, in the universal metamorphism of the oldest rocks.

PROVINCE I.—RADIATA [1]

Sub-Province POLYPI.

A polype is a small soft-bodied aquatic animal which generally presents a soft cylindrical oval or oblong body, with an aperture at one of its extremities, which is surrounded by a crown of radiating filaments or "tentacles." This aperture leads to the digestive cavity, which, in most Polypes, is without intestine or vent. A very large proportion of these animals has organs of support, called "polyparies" or corals, of various forms and substance, but for the most part consisting of carbonate of lime; and, as a general rule, locomotion is lost with the development of the polypary, which usually attaches the polype to some foreign body. The organization of the soft tissues is in general simple; the faculties of the Polypes are very limited; and the vital phenomena, save those of irritability and contractility, are inconspicuous. Nevertheless, the influence of the combined powers of some of the species, in adding to and modifying the crust of the earth, is neither slight nor of limited extent.

CLASS I.—HYDROZOA.

Char.—Polypary, when present, flexible, external; for the most part developing cells for the polypes according to regular patterns.

FAMILY I.—GRAPTOLITIDÆ.

To this class may probably belong the organic remains called "Graptolites," which are exclusively and characteristically Silurian fossils. A certain knowledge of their affinities would require examination of the soft parts; and the family has long been extinct. Indications of the flexible consistency of the polypary, and M. Barrande's statement of the existence of a cylindrical canal in its axis, which he conjectures to have contained the common connecting tissue of the polypes, have weighed with the writer in placing the Graptolites provisionally in the present class Polypi. The axis of the polypary is sometimes straight (fig. 3, *3*),

[1] For the characteristic organization of the provinces, classes, orders, and families of *Invertebrata*, reference may be made to the writer's *Lectures on Invertebrata*, 8vo, Longmans, 1855.

Radiata.

sometimes spiral (fig. 3, 6). The ordinary form, as given by the *Graptolites priodon* (fig. 3, 3), is serrated on one side only, and is found abundantly in the Cambrian or older Silurian beds of Scotland and Wales; it occurs also in the Ludlow rocks. The double Graptolites (*Diplograpsus*, fig. 3, 5, and *Didymograpsus*, fig. 3, 4) are Cambrian forms. *Rastrites* (fig. 3, 6) had the polypes only in one side, and they are less crowded: it characterizes Barrande's division E of the lower Silurian beds of Bohemia, and has not yet been found in Britain. The Graptolites occur in argillaceous strata, especially in the mud-stones of Wales and Cumberland, and in the alum-slates of Sweden. These beds remind one of the mud bottoms in which the Virgularia and other long aud slender graptolite forms of "Pennatulidæ" flourish in forest-like crowds. The primeval Graptolite may have presented a more generalized polype structure than is now met with in the specially differentiated Sertularians and sea-pens.

9. Archimedipora Archimedea, Lesuer.; *Carboniferous*, Kentucky.
10. Ptilopora pluma, M'C.; *Carboniferous*, Ireland.
11. Fenestrella membranacea, Ph.; *Carboniferous*, Britain

Class II.—ANTHOZOA.

In this class of Polypes the tentacles are hollow, and, in most, with pectinated margins. The polypary is usually internal, and forms the bodies more properly called "corals" and "madrepores."

Asteroida.—Great doubt attaches to some of the fossils referred to this class of Polypi. The terms "Gorgonia" and "Alcyonium" have been applied to objects not well understood, and usually proving to be *Bryozoa* and sponges. The lower Silurian fossil called *Pyritonema* consists of a fasciculus of silicious fibres, and has been supposed to be related to the glass zoophyte (*Hyalonema*). The miocene deposits of Piedmont contain a species of the Mediterranean genus *Corallium*, an *Antipathes*, and an *Isis* (or *Isisina*, D'Orb.), which is also found in Malta. The London clay contains one coral (*Graphularia*), referred to the *Pennatulidæ*, and two *Gorgonidæ* (*Mopsea* and *Websteria*).

Anthozoa or Actinoida.—The lamelliferous or stony corals are (next to the *Testacea*) the largest and most important class of invertebrate fossils. They attained a great development in the earliest seas, and were perhaps more widely diffused and individually abundant in the Silurian age than at any subsequent period. "Reef-building" corals are now confined to warm seas, and are wanting even on great tracts of tropical coast. The *Oculina* is the only large coral now found in the north. But in palæozoic times the representatives of the modern Astræas and Caryophyllias extended as far northward as Arctic voyagers have penetrated; and at a much later period they formed reefs of considerable thickness and extent in the area of the coralline oolite. The Silurian limestone of Wenlock Edge is itself a coral reef thirty miles in length; and the Plymouth limestone and carboniferous limestone have frequently the aspect of coral-banks skirting the older regions of Cambrian slate and Devonian "killas." The structure of coral-banks may be studied in the lofty limestone cliffs of Cheddar, and in the wave-worn shores of Lough Erne, as well as in the upheaved coral islands of the southern seas. In the fields about Steeple-Ashton, every stone turned up by the plough is a coral; and our inland quarries and chalk-pits afford to the palæontologist materials for the study of a class almost wholly wanting on the present sea-shores of Europe. The history of the British fossil corals, as given by Milne Edwards and Haime in the *Transactions of the Palæontographical Society*, exhibits, equally with that of the fossil shells by other authors, a transition from a state very different from that which now subsists in our part of the world, and a gradual approximation to the present order of things.

In the palæozoic strata the corals belong chiefly to two extinct orders; those of the secondary period more resemble living corals of warmer climates than ours; and the few tertiary genera and species resemble those of Southern Europe and our own coast.

The distinction between one large group of the palæozoic *Anthozoa* (*Cyathophyllidæ*) and more modern corals consists in the quadripartite character of their plaited cups or stars, whereas the lamellæ (or *septa*) of the other families are developed in multiples of 6. A remarkable exception exists in the *Holocystis* (fig. 5, 8), an Astrea-like coral with quadripartite stars, which is found in the lower greensand. The old-rock corals are also remarkable for the manner in which they are partitioned off by horizontal "tabulæ" (fig. 4, 3), like the septa of the *Nautilus* and *Spondylus*. This character obtains not only in the *Cyathophyllidæ*, but also in the *Milleporidæ*, *Favositidæ*, and other palæozoic families. Of the 129 Silurian corals, 121 belong to the tabulated divisions.

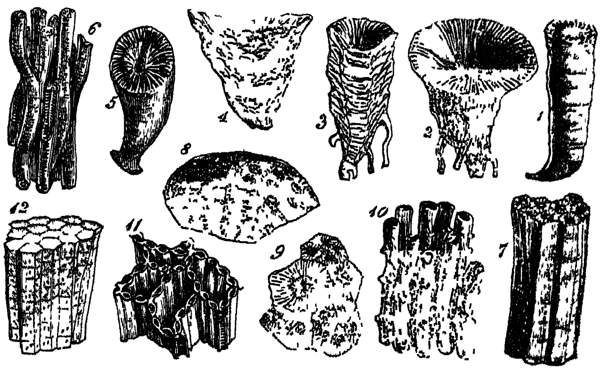

Fig. 4.

Palæozoic Corals (Anthozoa).

2. Cyathophyllum turbinatum, Lin.; *U. Silurian*, Wenlock.
3. Cyathophyllum subturbinatum (section); *U. Silurian*, Wenlock.
4. Cystiphyllum Siluriense, Lonsd.; *U. Silurian*, Wenlock.
5. Zaphrentis Phillipsi, M. Edw.; *Carboniferous*, Somerset.
6. Lithodendron irregulare, Ph.; *Carboniferous*, Europe.
7. Lithostrotion striatum, Flem.; *Carboniferous*, Europe.
8. Acervularia luxurians, Eich.; *U. Silurian*, Europe.
9. Heliolites interstincta, Wahl; *U. Silurian*, Europe.
10. Syringopora ramulosa, Goldf; *Carboniferous*, Europe.
11. Halysites catenulatus, L.; *Silurian*, Northern Regions.
12. Favosites Gothlandica, Lam.; *Silurian*, North.

The Devonian system contains about 150 described corals, the carboniferous limestone 76, and the magnesian limestone only 5 or 6. The commonest forms of simple, turbinated corals are *Cyathophyllum* (fig. 4, 2 and 3),

Radiata.

which exhibits four slight *fossulæ* in its cup, and is often supported by root-like processes. In *Zaphrentis* (fig. 4, 5) there is but one deep fossula. *Amplexus* (fig. 4, 1) is a characteristic carboniferous fossil, nearly cylindrical, and often so straight and regular in its growth as to have been originally described as a chambered shell. The radiating septa are very slight, and the horizontal partitions simple, flat, and almost as regular as the septa of the *Orthoceras*. In the Silurian *Cystiphyllum* (fig. 4, 4) the lamellæ are also evanescent; but the *tabulæ* are represented by numerous vesicular plates. The corals of these genera are not always solitary, or merely in groups; some species of *Cyathophyllum* constantly form compound masses, with cups rendered polygonal by contact, like *C. regium* of the Bristol limestone. The allied genus *Acervularia* (fig. 4, 8) resembles an *Astræa*, and exhibits in a remarkable manner the multiplication of its corallites by calicular gemmation. The genus *Lithostrotion* (fig. 4, 7) of the carboniferous limestone is also compact and astræiform, but the new corallites are produced by lateral gemmation. Corals with the same structure, but not compact, are known by the name *Lithodendron* (fig. 4, 6). The "chain-coral" (*Halysites*, fig. 4, 11) and *Syringopora* (fig. 4, 10) resemble at first sight the recent asteroid *Tubiporidæ:* in *Halysites* the radiating septa are quite rudimentary; and in *Syringopora* the tabulæ are funnel-shaped, forming a central axis to each tube. The *Favositidæ* (fig. 4, 12) are mostly very regular both as to their polygonal shape and transverse tabulæ; the cells of adjacent corallites are connected by pores, either in the sides or angles of the walls; the septa are rudimentary. In the genus *Chætetes* the tubes are always slender, and much elongated, and their walls imperforate. *Michelinia* resembles the fruit of the *Nelumbium ;* it has vesicular tabulæ and root-like processes to its basal plate. *Heliolites* (fig. 4, 9), of which many species are found in the Silurian and Devonian limestones, is related to the recent *Milleporas*. The radiating septa are distinct, and the tabulæ regular; the interspaces between the stars are filled up with fine and regular tubes. One genus of *Fungidæ* (*Palæocyclus*) occurs in the upper Silurian.

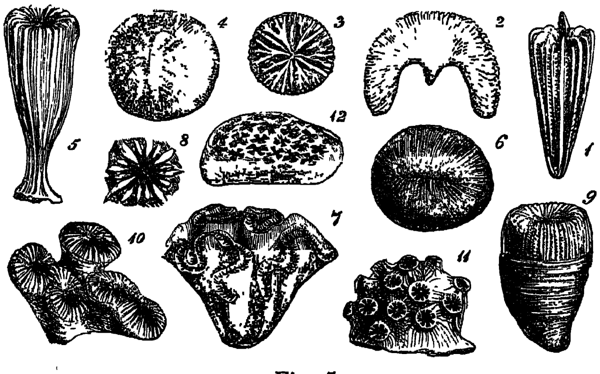

Fig. 5.

Secondary and Tertiary Corals (Anthozoa).

1. Turbinolia sulcata, Lam.; *M. Eocene*, Europe.
2. Diploctenium lunatum, Brug.; *Chalk*, France.
3. Micrabacia coronula, Goldf.; *U. Greensand*, Europe.
4. Aspidiscus cristatus, Lam; *Cretaceous* (?), Algeria
5. Cyclolites elliptica, Lam; *L. Chalk*, France.
6. Parasmilia centralis, Mant.; *U Chalk*, England.
7. Pachygyra labyrinthica, Mich.; *L. Chalk*, France.
8. Holocystis elegans, Lonsd.; *L. Greensand*, Isle of Wight.
9. Montlivaltia caryophyllata, Lam.; *Great Oolite*, France.
10. Stylina De la Bechei, M. Edw.; *Corallian*, Wilts.
11. Thecosmilia annularis, Flem.; *Corallian*, Wilts.

The British secondary corals are not very numerous; for although specimens abound in the coral-rag districts, only 14 species are found in that formation. Altogether, 65 species are found in the English oolites, and 22 in the chalk and greensands. These are mostly *Astræidæ*, or related to *Fungia*. Three common forms in the oolites are *Montlivaltia* (fig. 5, 9), *Stylina* (fig. 5, 10), and *Thecosmilia* (fig. 5, 11). The English cretaceous strata afford the *Holocystis* (fig. 5, 8), which is the most recent coral with quadripartite septa; *Trochocyathus* and *Parasmilia* (fig. 5, 6), resembling the recent *Cyathina ;* and the little "Fungia" *coronula* (fig. 5, 3), described in two genera of distinct orders (*Micrabacia* and *Stephanophyllia*) in the Monograph of the Palæontographical Society. The lower chalk of France and Germany contains many other corals, especially *Cyclolites* (fig. 5, 5), *Pachygyra* (fig. 5, 7), and *Diploctenium* (fig. 5, 2). The *Aspidiscus* (fig. 5, 4) was sent by Dr Shaw from Algeria.

The English *eocene* strata contain 25 corals, all extinct, and belonging to 15 genera. These include an *Astræa* (*Litharæa Websteri*), which grows on the water-worn flint pebbles; a *Balanophyllia*, similar to the existing coral; a *Dendrophyllia*, which is the oldest member of the genus; an *Oculina ;* and 8 species of the genus *Turbinolia* (fig. 5, 1). The corals of the English *pliocene* are mostly *Bryozoa ;* only four true corals have been found in the coralline crag, belonging to the genera *Sphenotrochus*, *Flabellum*, *Cryptangia*, and *Balanophyllia*, all reputed extinct, although the first is very closely related to the living *Sphenotrochus Macandrewi*.

The total number of fossil corals enumerated by M. D'Orbigny in the *Prodrome de Paléontologie* amounts to 1135, grouped under 216 genera. But notwithstanding all the labour which has been bestowed on this branch of palæontology by Goldfuss, Michelin, Lonsdale, and Milne Edwards, species are continually discovered or brought home from abroad which are altogether new, and cannot be placed in any of the constituted genera.

Class III.—BRYOZOA.

Char.—Tentacles of the polype hollow, with ciliated margins; alimentary canal with stomach, intestine, and anus; polypary, when present, external, horny, and calcareous.

The metamorphoses which the *Bryozoa* undergo are like those of the lower *Polypi ;* the embryo developed from the ovum is an oval, discoid, or subdepressed body, with a general or partial ciliated surface, by which it enjoys a brief locomotive life after its liberation from the parent. The *Bryozoa* are allied to the compound *Ascidia ;* but not one of the ascidian Molluscoids quits the ovum as a gemmule swimming by means of cilia; and no Bryozoon quits the ovum in the guise of a Cercarian or tadpole, to swim abroad by the alternate inflexions of a caudal appendage. In a progressive and continuous series of teachings, by pen or word of mouth, the place of an osculant or transitional group is governed by convenience, by considerations of how best to teach by comparison and easy gradation. The real merits of the man who would make scientific capital by changing the position of such group, and by imputing error or ignorance to the author from whom he may differ in this respect, are easily weighed and soon understood.

The *Bryozoa*, whether regarded as the highest organized Polypes, or as the lowest organized *Mollusca*, or as an intermediate type, are treated of in systematic palæontology in the position here assigned to them. The practical palæontologist finds himself compelled to arrange and study the fossil *Bryozoa* along with the corals, if only on account of the difficulty he in many cases experiences of determining to which class of Polypi his specimens belong. M. D'Orbigny, who has devoted much attention to this class, enumerates 544 fossil species, distributed in 73 genera. This number must be very far below the real one, since the *Bryozoa* of the chalk, which alone have been carefully examined, amount to 213 species; while only two species are known from the trias, none at all from the lias, and

only five from the upper oolites, so rich in corals and sponges. In the *Cours Elémentaire*, the fossil Bryozoa are stated to amount to 1676.

Of the 19 or 20 palæozoic genera, none extend into the secondary strata; but of the 18 oolitic genera, *Entalophora* and *Defrancia* range onwards to the tertiaries; and *Alecto*, *Idmenea*, and *Eschara* still survive. The oldest known fossil, *Oldhamia* (fig. 3, 2), is supposed to be a Bryozoon. The most common palæozoic form is *Fenestrella* (fig. 3, 11), resembling the recent "lace-coral;" there are 35 species, ranging from the lower Silurian to the Permian. One of its modifications resembles a feather (*Ptilopora*, fig. 3, 10), and is found in the carboniferous limestone. Another, more remarkable, has a spiral axis (*Archimedipora*, fig. 3, 9), and occurs in the same formation in Kentucky. One of the oldest genera is *Ptilodictya* (fig. 3, 8), of which 7 species are found in the lower Silurian formations. The slabs of Silurian limestone obtained at Dudley are covered with myriads of small and delicate fossils, including many *Bryozoa*. Some of these are spread like a film over other fossils, and have been doubtfully referred to the modern genera *Discopora* and *Berenicea;* others, with slender branches, and erect or creeping, are called Milleporas, Heteroporas, and Escharinas. The genus *Cœnites* (fig. 3, 7) perhaps belongs here. The magnesian limestone contains several large "lace-corals" of the genera *Fenestrella*, *Synocladia*, and *Phyllophora;* and two branching species of *Thamniscus* and *Acanthocladia*. The oolites afford many small incrusting species related to *Diastopora*, and branching forms like *Terebellaria* and *Chrysaora*. In the chalk, the *Escharas* are most numerous, and *Lunulites* and *Cupularia* first appear. Some thin beds of the lower chalk are almost composed of *Bryozoa*, mingled with *Foraminifera*. The coralline crag of Suffolk takes its name from the great abundance of *Bryozoa* it contains, among which *Eschara*, *Cellepora*, *Fascicularia*, *Theonoa*, *Hornera*, *Idmonea*, *Flustra*, and *Tubulipora* are the most important.

Class IV.—Echinodermata.

(*Star-Fishes, Sea-Urchins.*)

Char.—Marine; commonly free, repent animals, with the integument in most perforated by erectile tubular tentacles, hardened by a reticulate deposit of calcareous salts, and in many armed with spines.

The fossil Radiata present a mine of comparatively unexhausted richness to the palæontologist. More difficult of study than shells, and less uniformly present in all strata, the enduring remains of *Echinodermata* and corals are unsurpassed in beauty of form and structure, and in the value of the evidence they afford.

The present summary of the extinct forms of *Echinodermata* will commence with

Order 1.—Crinoidea.

Char.—Body with ramified rays, supported temporarily or permanently on a jointed calcareous stem; alimentary canal, with mouth and vent, both, as in Bryozoa, approximated.

The "stone-lilies," or crinoid star-fishes, formed a numerous and important group in the palæozoic seas, where they obtained their maximum number and variety. M. D'Orbigny describes 31 palæozoic genera, 2 triassic, 10 oolitic, and 4 cretaceous—of which latter 3 (*Pentacrinus*, *Bourgueticrinus*, and *Comatula*) are found in the tertiaries and modern seas. The *Crinoidea* differ from the other Echinoderms in having the generative organs combined with the arms, and opening into special orifices near their

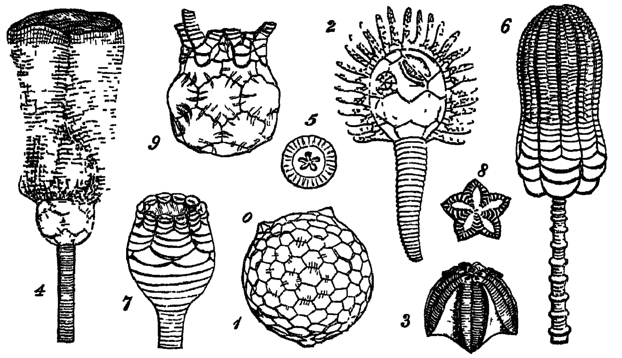

Fig. 6.

Crinoidea; Blastoidea; Cystoidea

1. Sphœronites aurantium, Wahl.; *L. Silurian*, Sweden.
2. Pseudocrinus bifasciatus, Pearce; *U. Silurian*, Dudley.
3. Pentremites florealis, Say; *Carboniferous*, Ohio.
4. Crotalocrinus rugosus, Mill.; *U. Silurian*, Dudley.
5. Poteriocrinus (joint of column); *Carboniferous*, Yorkshire.
6. Encrinus entrocha; *L. Muschelkalk*, Germany.
7. Apiocrinus Parkinsoni, Mill.; *Bradford Clay*.
8. Pentacrinus basaltiformis, Mill.; *Lias*, Lyme.
9. Marsupites ornatus, Mill.; *Chalk*, Sussex.

base. Nearly all the genera, except *Comatula* and *Marsupites* (fig. 6, 9), appear to have been attached either by the expanded base of the column, as in *Apiocrinus*, or by jointed processes, as in *Bourgueticrinus*. In many instances the lower part of the column throws out innumerable root-like side-arms, which strengthen and support it. The column is comparatively short in *Apiocrinus Parkinsoni*, and extremely elongated in *Pentacrinus Hiemeri*. It is round in nearly all the palæozoic Crinoids; and when five-sided, the articular surfaces of the joints are simply radiated, as in the rest. These joints are perforated in the centre, and when detached, are the "St Cuthbert's beads" of story (fig. 6, 5).[1] In *Platycrinus* the stem is compressed, and the articular surfaces are elliptical. In the genus *Pentacrinus*, which commences in the lias, the sculpturing of the articulations is more complex (fig. 6, 8), but it is quite simple in the other modern genera. The body of the Crinoid is composed of polygonal plates forming a cup, which is covered by a canopy of smaller plates. The mouth is often proboscidiform; the anal orifice is near it. The five arms which crown the cup are sometimes nearly simple, but feathered with slender, jointed fingers; in other genera they divide again and again, dichotomously; and in two remarkable Silurian forms, *Anthocrinus* and *Crotalocrinus* (fig. 6, 4), these subdivisions are extremely numerous, and the successive ossicles are articulated to each other laterally, forming web-like expansions, similar in appearance to the coral *Fenestrella* (fig. 3, 11.) Other remarkable Silurian Crinoids belong to the genera *Glyptocrinus*, *Eucalyptocrinus*, *Geocrinus* (the "Dudley Encrinite"), and *Caryocrinus*. Several are common to the Silurian and Devonian, as *Melocrinus*, *Cyathocrinus*, and *Rhodocrinus;* the two last, and *Poteriocrinus*, extend into the carboniferous formations. *Cupressocrinus* and some others are peculiarly Devonian; *Platycrinus*, common to Devonian and coal formations; and many genera (including the "nave Encrinite,"—*Actinocrinus*, *Gilbertsocrinus*, and *Woodocrinus*), are proper to the carboniferous limestone. The famous "lily Encrinite" (*Encrinus entrocha*, fig. 6, 6) is characteristic of the middle trias, or "muschel-kalk;" the "clove Encrinite" (*Eugeniacrinus*, fig. 7, 9) abounds in the Ox-

[1] Casts, in chert, of the canal which passes down the crinoidal column are called "screw-stones;" and those limestones which abound in columns and detached joints are called "entrochal marbles."

Radiata.

fordian oolites of Germany; *Apiocrinus*, *Millericrinus*, and several forms related to *Comatula*,—*e.g.*, *Pterocoma* and *Saccosoma*,—are also peculiarly oolitic. The "tortoise Encrinite" (*Marsupites*, fig. 6, 9) is found only in the chalk, along with *Bourgueticrinus* (fig. 7, 10); and the bodies of *Comatulæ*, which, when they have lost their arms and claspers, are called "Glenotremites." (Fig. 7, 7,—upper surface with sockets of the five arms; 8 under surface, showing articulations of claspers, and the scar of the larval stem.)

Order 2.—CYSTOIDEA.

This order was established by Von Buch for a small group of palæozoic Echinoderms formerly included with the *Crinoidea*. They have a globular body covered with close-fitting polygonal plates attached by a simple, jointed stem. The mouth is minute, and opposite to the stalk; close to it is the small anal opening; and a little more distant the generative orifice, covered by a pyramid of five or six little valves. Some of the genera, like *Pseudocrinus* (fig. 6, 2), have two or four tentaculiferous arms, bent down over the body and lodged in grooves, to which they are anchylosed. Others, like the *Sphæronites* (fig. 6, 1), have only obscure indications of tentacles situated close to the mouth. In *Pseudocrinus* and some other genera two or three pairs of lamellated organs, called *pectinated rhombs*, are placed on the contiguous margins of certain body-plates. They are supposed not to penetrate the interior, and no office has been conjecturally assigned to them; but Professor Forbes suggested that they might represent the "epaulettes" of the larval *Echinidæ*, to which group he supposed the Cystidean bore the same relation as the Crinoids hold to the star-fishes. There are 9 genera, of which 8 are found in the British strata—4 in the upper and 4 in the lower Silurian.

Order 3.—BLASTOIDEA.

A separate order has been proposed for another small group of palæozoic fossils typified by *Pentremites* (fig. 6, 3). The body is globular or elliptical, and supported on a small, jointed stalk, with radiated articular surfaces and irregular side-arms. It is composed of solid polygonal plates, with a minute oral orifice at the summit surrounded by five other openings, four of which are double and ovarian, the fifth rather larger and anal. There are five petaloid ambulacra of variable length, converging to the mouth, furrowed down the centre, and striated across. According to the observations of Dr Ferdinand Rœmer, these supported numerous slender, jointed tentacula, indicated by the rows of marginal pores. One species is found in the upper Silurian, 6 in the Devonian, and 24 in the carboniferous, which has received the name of "pentremite limestone" in the United States, on account of the abundance of these fossils it contains.

Order 4.—ASTEROIDEA.
(*Sea-Stars, Brittle Stars.*)

Char.—Body radiate; integument hardened by calcareous pieces, and more or less armed with spines; no dental apparatus.

Asteriadæ and Ophiuridæ.—Fossil star-fishes, though less common, have a wider range than their allies the fossil urchins, being found amongst the earliest organic forms. *Palæaster*, *Protaster* (fig. 7, 6), and *Lepidaster* (fig. 7, 5), are Silurian star-fishes, presenting many anomalies, and scarcely referable to any existing families. *Tropidaster*, *Pleuraster*, *Aspidura*, *Ophiurella*, and *Amphiura* are oolitic genera; *Ophiodermea*, *Luidia*, and *Astropecten* range from the lias to the present seas; *Stellaster* and *Arthraster* are peculiar to the cretaceous; and *Ophiura*,

Radiata.

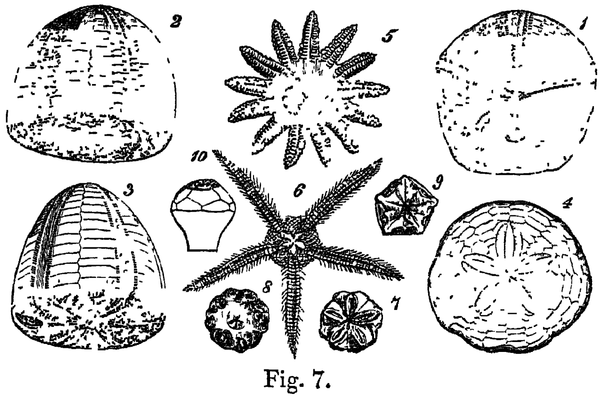

Fig. 7.

Galeritidæ; Asteriadæ; Crinoidea.

1. Pygaster semisulcatus, Ph.; *Inf Oolite*, Cheltenham.
2. Ananchytes ovatus, Lam; *U Chalk*, Europe.
3. Galerites albogalerus, Lam; *U. Chalk*, Kent.
4. Scutella subrotunda; *Miocene*, Malta.
5. Lepidaster Grayi, Forbes; *U Silurian*, Dudley.
6. Protaster Miltoni, Salter; *L. Ludlow rock*, Salop.
7. Comatula (Glenotremites), upper surface of body.
8. Comatula (lower surface); *Chalk*, Sussex
9. Eugeniacrinus quinquedactylus, Schl, *Oxfordian*, Wurtemberg.
10. Bourgueticrinus ellipticus, Mill; *Chalk*, Kent.

Astrogonium, *Oreaster*, and *Goniodiscus* are both cretaceous and living.

Order 5.—ECHINOIDEA.
(*Sea-urchins*)

Char.—Body spheroid or discoid, incased in a crust of inflexibly-joined calcareous plates, and armed with spines; dental system complex, arranged so as to resemble a "lantern."

The *Echinoidea* appear first in the carboniferous limestone, and attain their maximum in the cretaceous strata. In all secondary and more modern *Echinidæ*, the shell is composed of five double rows of ambulacral plates, and five inter-ambulacral; but in the *Palæchinus* (fig. 8, 1), of the carboniferous limestone there are six rows of inter-ambulacral plates, and in *Perischodomus* five. Only detached plates of *Archæocidaris* (fig. 8, 2) have been seen, and

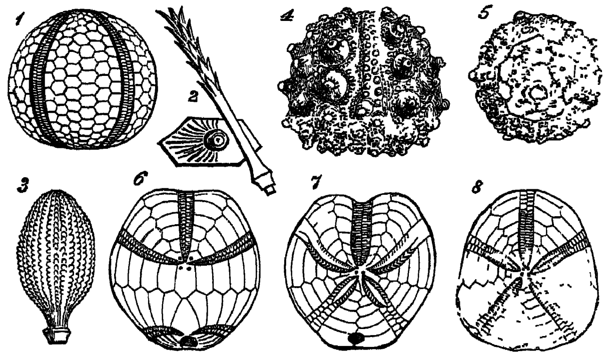

Fig. 8.

Echinidæ; Spatangidæ.

1. Palæchinus sphæricus, Scouler; *Carboniferous*, Ireland.
2. Archæocidaris Urii, Flem.; *Carboniferous*, Ireland.
3. Cidaris glandifera, Goldf. (spine); *Jura*, Mount Carmel.
4. Hemicidaris intermedia, Flem.; *Corallian*, Calne.
5. Salenia petalifera, Desm.; *U. Greensand*, Wilts.
6. Disaster ringens, Ag.; *Inferior Oolite*, Dorset.
7. Hemipneustes Greenovii, Forbes; *U. Greensand*, Blackdown.
8. Catopygus carinatus, Goldf.; *U. Greensand*, Wilts.

these, by their six-sided form, seem also to have been arranged in more than double series. Normal Echinidæ, of the existing genus *Cidaris*, abound in the upper *trias*.

Radiata.

Some of the secondary species of Cidaris have the ambulacral pores widely separated (=*Rhabdocidaris*); in others the rows of pores are doubled (=*Diplocidaris*). The genus *Hemicidaris* (fig. 8, 4), distinguished by the large spine-bearing tubercles on the lower part of the ambulacra, ranges from the trias to the chalk-marl. *Diademæ*, with smooth, solid spines (=*Hemidiadema*), appear in the lias, and continue to the chalk, where the modern type, with annulated, hollow spines, appears. *Echinopsis* also occurs in the lias; and *Acrosalenia*, a genus characteristic of the oolites, and distinguished from *Salenia* by its perforated tubercles. *Acrocidaris* and *Heliocidaris*, with *Glypticus*, and several other sub-genera of Echinus, are also peculiar to the oolites. *Salenia* (fig. 8, 5), with its ornamental disk, is characteristically cretaceous. *Arbacia* and *Temnopleurus* appear first in the eocene. The *Cassidulidæ* commence in the oolites, with *Pygaster* (fig. 7, 1) and *Holectypus*, and abound in the cretaceous system. *Galerites* (fig. 7, 3), *Discoidea*, *Pyrina*, and *Cassidulus* are peculiar to the chalk. The *Clypeastridæ* are represented in the oolites by numerous species of *Echinolampas* and *Nucleolites* (or *Clypeus*); the latter genus attains a large size. The sub-genus *Catopygus* (fig. 8, 8) is peculiar to the cretaceous series. *Conoclypeus* occurs in the chalk and tertiaries. *Clypeaster* flourished most in the miocene age; many large species are found in the south of Europe, Madeira, and the West Indies. Numerous genera, remarkable for their flattened form, and popularly known as "cake-urchins," are peculiar to the tertiaries and existing seas. *Lenita* and *Scutellina* are eocene; *Scutella* (fig. 7, 4) is miocene. *Mellita* and *Echinarachnius* are both fossil and recent. The heart-shaped urchins (*Spatangidæ*), are only remotely represented in the oolites by *Disaster* (fig. 8, 6); they are numerous in the chalk, to which *Micraster*, *Hemipneustes* (fig. 8, 7), *Archiacia*, *Holaster*, and *Ananchytes* (fig. 7, 2), are peculiar. *Hemiaster* is cretaceous and tertiary. *Spatangus*, *Eupatagus*, *Brissus*, *Amphidotus*, and *Schizaster* are tertiary and recent forms.

The shell of the *Echinodermata* has the same intimate structure in all the orders and families, and in every part of the skeleton, whether "test," or "spine," or "tooth." The smallest plates resemble bits of perforated card-board, and the largest and most solid are formed of a repetition of similar laminæ. In a few membranous structures, minute spicula, curved, bi-hamate, or anchor-shaped, are met with. They are always composed of carbonate of lime; but owing to their porosity, fossil examples are commonly impregnated with earth, or pyrites, or silica, and form bad subjects for microscopic investigation. Without, however, losing their organic structure, the fossil Echinoderms exhibit a cleavage like that of calcareous spar, by which the smallest ossicle of star-fish or Crinoid may be recognised: this peculiarity is most strikingly obvious in the great spines of the *Cidaris* (fig. 8, 3), or the enlarged column of the "pear Encrinite" (fig. 6, 7). Examples of the latter may be seen which had been crushed when recent, and before the sparry structure was superinduced.

Order 6.—HOLOTHURIOIDEA.

(*Sea-Cucumbers, Trepang.*)

Char.—Body vermiform; integument flexible, with scattered reticulate calcareous corpuscles, or beset with small anchor-shaped spicula.

The Holothurioid order presents scarcely any examples likely to be met with in a fossil state, except the genus *Psolus*, of whose imbricated shield a fragment has been found by Mr Richmond in the northern drift of Bute. Count Münster has figured the microscopic plates, apparently of a *Holothuria*, from the chalk of Warminster; and the anchor of a *Synapta* from a still older formation,—the upper oolite of Bavaria.[1] Microscopic observers will doubtless meet with many such detached plates and spines when searching for Polycystineæ and other Rhizopods in the oolitic and cretaceous strata; but it is scarcely probable that the order has dated far back in time.

Articulata.

PROVINCE II.—ARTICULATA.

In the great division of invertebrate animals called *Articulata* the brain is in the form of a ring encircling the gullet. A double ganglion above the tube supplies the chief organs of sense. The ganglions below the tube are connected with two chords which extend along the ventral surface of the abdomen, and are in most species united at certain distances by double ganglions, which are connected with the nerves supplying the body segments and their appendages. The body presents a corresponding symmetrical form. The skeleton is external, and consists of articulated segments of a more or less annular form. The articulated limbs, in the species possessing them, have a like condition of the hard parts, in the form of a sheath which incloses the muscles. The jaws, when present, are lateral, and move from side to side.

The worm, the lobster, the scorpion, and the beetle exemplify this province.

The articulate division of the animal kingdom, most universally distributed and numerically abundant at the present day, is least perfectly represented amongst the relics of the former world. Their chitinous integuments, often hardened with earthy salts, are quite as capable of preservation as the shells of the *Mollusca*, and remains of them are met with in all aqueous deposits; but that manifold, complex organization, which in the recent state fits them so admirably for generic and specific comparisons, is fatal to their entire preservation, and the fossil examples are often so fragmentary as to admit of little more than the determination of their class and family.

The most ancient fossiliferous rocks bear imprints which have been regarded as the tracks and burrows of marine worms. With these are found Crustacea of the lowest division, and of a group which is wholly extinct. A little later appear the Phyllopods, Copepods, and other existing orders of *Entomostraca*. Only a few obscure forms, doubtfully referred to the higher division *Malacostraca*, have been found in the carboniferous and Permian systems. The secondary strata contain abundant remains of Isopods, and of lobsters and hermit-crabs. True crabs (*Brachyura*) abound in the oldest tertiaries. Air-breathing insects and Arachnida existed even in the palæozoic age; the "sombre shades" of the carboniferous forests were not "uncheered by the hum of insects;" nor were the insects blind, like those which now inhabit the vast caverns of Kentucky and Carniola. The *Articulata* which come latest are the Cirripedes, whose lowest family appears in the lias; while the *Balanidæ* are only found in the tertiaries.

The number of fossil Articulata catalogued and described forms but a very small proportion of those which have probably existed. Bronn enumerates 1551 fossil insects: 131 Arachnida, 894 Crustacea, and 292 Anellida. Darwin describes 69 fossil Cirripedes, 12 of which are living species.

CLASS I.—ANELLIDA.

(*Worms, Tube-Worms, Nereids.*)

Char.—Body soft, symmetrical, vermiform, annulated, with suckers, or setæ, or setigerous tube-feet; blood of a red colour in most.

[1] Beitrage, heft 6, 1843.

The peculiar markings on the surface of the old Cambrian slate rocks, conjectured to afford the earliest indications of the existence of marine worms, are not without suspicion as to their origin. The so-called "Nereites" bear considerable resemblance to other equally ancient impressions which have been described as Zoophytes, under the name of *Protovirgularia* (fig. 3, 1). No such doubt attaches to the worm-tracks which abound in the thin-bedded sandy strata of the forest-marble; and the "Cololites" of the lithographic limestone are most probably the castings of worms. Long calcareous tubes occur in the upper Silurian and carboniferous strata, which have received the name of *Serpulites*. The *Microconchus* of the carboniferous period is now regarded as an Anellide; and in all the later formations, tubicolar Anellides, especially of the genera *Serpula*, *Spirorbis*, and *Vermilia* abound. Some of these, although attached and gregarious, are so regular in their growth as to have been usually called *Vermeti*, but are now placed in the genus *Vermicularia*. *Spiroglyphus*, and some other shell-excavators, are indicated in the tertiaries. Amongst the problematic fossils of the palæozoic strata, two are supposed to be *anellidous*,—viz., the *Tentaculites* (fig. 10, 7), which was apparently free, and almost always regular in its growth, so as more to resemble one of the gregarious Pteropods; and the *Cornulite* (fig. 10, 8), which is attached when young, singly or in groups, to Silurian shells and corals: the structure of its shell is vesicular, and the cavity resembles a series of inverted cones. The unattached and gregarious *Ditrupa* appears in the upper chalk, and abounds in the London clay and crag.

Class II.—CIRRIPEDIA.

(Barnacles, Acorn-Shells.)

Char.—Body chitinous or chitino-testaceous, subarticulated, mostly symmetrical, with aborted antennæ and eyes; thorax attached to the sternal surface of the carapace, with six pairs of multiarticulate, biramous, setigerous limbs; metamorphosis resulting in a permanent parasitic attachment of the fully-developed female to some foreign body.

The fossil Cirripedes belong chiefly to the sessile division, and consist of the ordinary forms of the still-existing *Balanidæ*. They are rare in the eocene tertiary, but more abundant afterwards. The *Balanus porcatus* attains a great size in the shelly beds of northern drift; its large basal plate, when detached, is a puzzling fossil, and has caused some mistakes. A *Coronula* has been found in the middle division of the crag which has afforded so many cetaceous bones. Remains of pedunculated Cirripedes occur in older deposits, but are mostly scarce and fragmentary. A species of *Pollicipes* is found adhering to drift-wood, perforated by bivalves, in the lias; another occurs in the Oxford clay, attached in groups to drift-wood, and the shells of Ammonites, which probably floated in the sea after death. The chalk affords many species of *Pollicipes* and *Scalpellum*, a species of the anomalous genus *Verruca*, and the only extinct genus of Cirripedes—*Loricula* (fig. 10, 6). This remarkable fossil is found attached to Ammonites, and exhibits only one side in any of the examples hitherto found. In this unsymmetrical development and the imbrication of its valves it more resembles *Verruca* than any other Cirriped. "During the deposition of the great cretaceous system, the *Lepadidæ* arrived at their culminant point: there were then three genera, and at least thirty-two species;" whereas at the present day the Philippine Archipelago, which is the richest marine province, affords but five species.

Class III.—CRUSTACEA.

Char.—Body articulated, with articulated limbs; head with antennæ; branchial respiratory organs; sexes distinct; metamorphosis in most, in none resulting in fixed individuals.

Sub-Class 1.—ENTOMOSTRACA.

Char.—Body with more or fewer segments than fourteen; integument chitinous, forming in some a bivalve shell; eyes sessile.

Small bivalve entomostracous Crustacea are found in all strata, and attain their maximum size in the older rocks. Minute *Ostracoda*, related to the recent *Cypris* (fig. 10, 5), swarm in the laminated fresh-water clays of the Wealden;

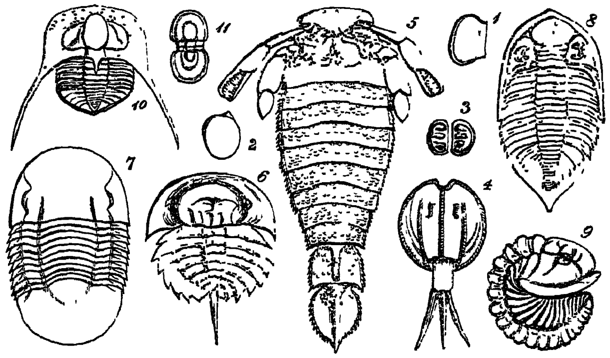

Fig. 9.

Palæozoic Entomostraca.

11. Agnostus trinodus, Salter; *L. Silurian*, Britain.

whilst the marine *Cytheridæ* assist with their multitudinous atoms in building up the chalk. Amongst the Phyllopods, the gregarious *Estheria* covers the slabs of Wealden and of Keuper with crowds of bivalve shells which have been commonly mistaken for *Cyclades* and *Posidonomyæ*. The globose *Entomoconchus* (fig. 9, 2) is found in the carboniferous limestone; *Leperditia* (fig. 9, 1) in the Silurian rocks of the north; and *Beyrichia* (fig. 9, 3), which is characteristically Silurian, may be distinguished from the young forms of Trilobites by the unsymmetrical shape of its separated valves. Other palæozoic Phyllopods (*Ceratiocaris* and *Hymenocaris*) related to the recent *Nebalia*, and having a conspicuous tail, occur in the upper and lower Silurian strata; the genus *Leptocheles* (M'C.) was founded on the tail-spines of these *Crustacea*. *Dithyrocaris* (fig. 9, 4), which resembles the recent *Apus* in the horizontal compression of its carapace, is found in the carboniferous limestone. The lower coal measures also contain in their nodules of clay-ironstone frequent examples of *Bellinurus* (fig. 9, 6), a small Pœcilopod, differing from the recent king-crab (*Limulus*) in the moveable condition of the body-segments. But the most extraordinary of the palæozoic Crustacea are the *Eurypterus*, *Himantopterus*, and *Pterygotus* (fig. 9, 5[1]), from the upper Silurian and old red sandstone, of which some far surpassed the largest living lobster or king-crab in size. They have been considered an extinct family, related to the *Limuli*; or as the repre-

[1] This figure (by Mr Salter), as well as several others, are taken from the *Siluria* of Sir R. Murchison, P.G.S.

sentatives of the larval condition of the stalk-eyed *Malacostraca*. But the following structures show an affinity to the *Ostracoda*. Their carapace is comparatively small, with compound eyes on the antero-lateral margins; the body segments are eleven or twelve in number, without appendages, and terminated by a pointed or bilobed tail. *Eurypterus* has eight feet; the others have three pairs of limbs,—viz., the chelate antennæ, the foot-jaws, and the natatory feet, with their fin-like palettes, which spring from the under side of their cephalo-thorax. The surface of the body and limbs often presents a peculiar imbricated sculpture, which caused them at one time to be regarded as fishes by Agassiz. The *Pterygotus problematicus* is supposed to have attained a length of seven feet, and some of the others were a yard long. Crustacea of this magnitude may have formed tracks on the sea-bed, like those on the Potsdam sandstone of America, called "Protichnites," subsequently to be described.

The great family of Trilobites is entirely confined to the palæozoic age; none are found even in the upper coal measures or Permian system. Above 400 species have been described, and grouped in 50 genera. Of these, 46 are Silurian, 22 Devonian, and 4 carboniferous. According to Bronn, 13 genera are peculiarly lower Silurian, 3 upper Silurian, 1 Devonian, and 3 carboniferous.

Order TRILOBITES.

Char.—Trunk segments trilobed; sessile compound eyes in most; limbs aborted.

The skeleton of the Trilobite consists of the cephalic shield, a variable number of trunk-rings or segments, and the *pygidium* or tail composed of a number of joints more or less anchylosed. In some species a *labrum* (or "hypostome") has been discovered, but no indications of antennæ or limbs have ever been detected; still there can be no doubt they enjoyed such locomotive power as even the limpet and chiton exhibit when requisite. Variations in the length of the cephalic and caudal spines (*e.g.*, in *Asaphus caudatus* and *longi-caudatus*), and in the prominence of the head-lobes, have been considered indications of difference of sex. One of the oldest and simplest forms is the minute *Agnostus* (fig. 9, 11); it is usually found in little shoals, with only the cephalic shield preserved, as if it were the larval form of some large Trilobite. According to the observations of M. Barrande, the *Sao* passes through twenty stages of growth, being first a simple disc, and ultimately having seventeen free thoracic segments and two caudal joints; the additional segments are developed between the thorax and abdomen. The *Trinucleus* (fig. 9, 10) with its ornamental border, and *Illænus* (fig. 9, 7), in which the trilobation is less conspicuous than in most genera, are characteristic of the lower Silurian strata. Two others from the Wenlock limestone have long been celebrated,—viz., *Calymene* (fig. 9, 9), or the "Dudley Trilobite," so compactly rolled up; and *Asaphus* (or Phacops) *caudatus* (fig. 9, 8), in which the lenses of the large eyes are frequently well preserved, and visible without a glass. Each eye has at least 400 facets, and in the great *Asaphus tyrannus* each is computed to have 6000. In one species (*Asaphus Kowalewskii*) the eyes are supported on peduncles. The largest Trilobite is *Asaphus gigas*; some of the fragments indicate a creature eighteen inches long.

Sub-Class 2.—MALACOSTRACA.

Char.—Body divided into thorax and abdomen, with seven segments in each.

The *Isopods* are represented in the upper oolite by *Archæoniscus Brodiæi*, which is gregarious, in large numbers in the slabs of Purbeck limestone; and in the Permian system by the *Prosoponiscus* (or *Palæocrangon*). The problematic *Pygocephalus*, and the "*Apus dubius*," both from the carboniferous strata, are doubtfully referred to the *Stomapoda*, and, with the exception of the *Gitocrangon* of Richter, are the oldest of the known stalk-eyed Decapods.

Macrourous Crustacea are of constant occurrence

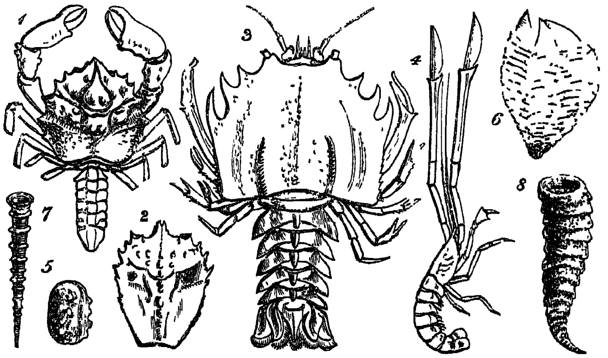

Fig. 10.

Crustacea; Annelida.

1. Dromilites Lamarckii, Desm; *London Clay*, Sheppy.
2. Notopocorystes Stokesii, Mant.; *Gault*, Folkestone.
3. Eryon arctiformis, Schl.; *Oxfordian*, Solenhofen.
4. Megachirus locusta, Germar; *Oxfordian*, Solenhofen.
5. Cypridea tuberculata, Sby; *Weald*, Sussex.
6. Loricula pulchella, G B. Sby; *L Chalk*, Sussex.
7. Tentaculites ornatus, J. Sby.; *U. Silurian*, Dudley.
8. Cornulites serpularius, Schl.; *U. Silurian*, Dudley.

throughout the oolites and cretaceous strata. One of the most remarkable forms, *Eryon* (fig. 10, 3), is found in the lias (with the closely-allied *Tropifer* and *Coleia*) and in the Oxford clay. The small lobsters of the genus *Glyphea*, in the oolites, and *Meyeria*, in the Speeton clay and greensand, are commonly the nucleus of hard nodules of phosphate of lime. The larger species of the chalk form the genus *Enoploclytia*. The Oxfordian oolite of Solenhofen, with its finely-laminated lithographic slates, opens like a book filled with compressed and wonderfully-preserved shrimps and lobsters. One of them, remarkable for its long and slender arms (*Megachirus*, fig. 10, 4) is also found in the Oxford clay of Wiltshire. One of the most remarkable repositaries of fossil Crustacea is the Isle of Sheppy, where the "London clay" has afforded countless examples of the higher organized division, including 9 Brachyura, 3 Anomura, and 5 macrourous species. The island of Hainan, on the coast of China, abounds with fossil crabs of the genus *Macropthalma*, which are sold in the drug-market of Shanghae. Others are found in the miocene of Malta, and of Perim Island in the Red Sea. The reputed instances of secondary *Brachyura* are open to doubt; in England we have only the little *Etyus Martini* (or *Reussia*) from the gault, for the *Podopilumnus* (M'C.) is probably from some foreign tertiary deposit. Pairs of chelate claws occur in the upper chalk which are referred to a hermit-crab (*Mesostylus Faujasii*). Small Crustaceans, resembling in form the living *Corystes*, abound in the gault (fig. 10, 2), but they are known to be anomourous by the small size and dorsal position of the posterior legs, and by the little plates intercalated between the last joints of the tail, as seen also in the *Dromilites* (fig. 10, 1) from the London clay.

CLASS IV.—INSECTA.

Char.—Body chitinous, articulated, with articulated and uncinated limbs; head provided with jointed antennæ; respiratory system tracheal.

The fossil insects hitherto examined have afforded no new types or forms of unusual interest. The oldest known, those from the lower coal measures, resemble the *Curculionidæ* and *Blattidæ* or *Locustidæ* of the pre-

sent day. The lias limestones have afforded a greater variety to the persevering skill of Mr Brodie: species of the genera *Berosus*, *Elater*, *Gyrinus*, *Laccophilus*, and *Melolontha*, and undetermined genera of the families *Carabidæ*, *Buprestidæ*, *Chrysomelidæ*, and *Telephoridæ;* Panorpa-like insects of the genus *Orthophlebia;* dragonflies, *Nepadæ* and *Cimicidæ*, *Cicada*, and the dipterous genus *Asilus*. Next in age is the insect depositary of the Stonesfield slate, which affords the large wing-covers of *Buprestis Bucklandi*, species of *Prionus* and *Coccinella*, and the great neuropteran *Hemerobioides*. The Purbeck limestone has supplied, in addition, species of *Cerylon* and *Colymbetes*, *Cyphon*, *Elophorus*, and *Limnius;* and examples of *Staphylinidæ*, *Cantharidæ*, *Harpalidæ*, *Hydrophilidæ*, and *Tenebrionidæ*, *Libellula* and *Phryganea*, *Acheta* and *Blatta*, *Aphis*, *Cercopis*, and other Homoptera, and ten dipterous genera. In the newer pliocene freshwater formations the recent *Copris lunaris* has been detected, and the elytra of *Donacia* and *Harpalus*. The principal foreign sources of fossil insects have been the lithographic slates of Solenhofen, and the tertiary deposits of Aix in Provence, and Œningen, near Constance, on the Rhine. Remains of species of *Tinea* and *Sphinx* are said to have been found in the lower Jura, and of a diurnal Lepidopteran in the Molasse. Numerous examples of insects in true amber have been obtained, and much more abundantly in "gum animi," a more modern fossil resin. These are all unknown to entomologists, and are probably extinct, since no department of recent natural history has been so closely worked, although the fossil insects have been comparatively neglected. It has been suggested by Mr Westwood that the lias insects have a sub-alpine character, and may have been brought down by torrents from some higher region. But no attempt has been made to show whether these or any other group of fossil insects most nearly resemble those of any particular zoological province of the present day.

Much has been said of the "indusial limestone" of Auvergne, supposed to be built up of the fossilized cases of caddis-worms (*Phryganeidæ*); but the only entomologist who has visited the country and examined the formation entertains doubts of the correctness of this interpretation.

Of the *Myriapoda*, 17 fossil species have been found, commencing in the oolitic system. And of the *Arachnida*, 131 species are catalogued; the earliest and most interesting of these is the fossil scorpion (*Cyclopthalmus senior*) of the Bohemian coal measures (figured in Buckland's *Bridgewater Treatise*). Fossil spiders are found in the Solenhofen slates and in the tertiary marls of Aix.

Province III.—MOLLUSCA.[1]

Remains of the *Testacea*, or shell-bearing molluscous animals, are the most common of all fossils, and afford the most complete series of "medals," or characteristic signs for the identification of strata. The duration of types and species, as a general rule, is inversely proportional to rank and intelligence. The most highly organized fossils have the smallest range, and mark with greatest exactitude the age of the deposit from whence they have been derived. But the evidence afforded by shells, if less precise, is more easily and constantly obtained, and holds good over larger tracts of country.

Class I.—BRACHIOPODA.

The lamp-shells (*Brachiopoda*), more than any other group, have suffered with the lapse of time. Of 1300 known species, only 75 are living; and of the 34 genera, the larger part (21) are extinct. The number of generic forms is greatest in the Devonian period and least in the upper oolites, after which a second set of new types gradually appears. The preponderance of fossil *Brachiopoda* is contrasted with the scarcity of the recent shells even more strongly by the abundance of individuals than by the number of species; for the living shells mostly inhabit deep water and rocky situations inaccessible to the dredger, and are seldom obtained in large numbers.

The genus *Terebratula*, as now restricted to shells with a short internal loop, musters above 100 fossil species, of which only one survives (*T. vitrea*), an inhabitant of the Lusitanian province.

The Waldheimias, or *Terebratulæ*, with long loops, are widely distributed in our present seas, although only 9 in number, being found on the coast of Spitzbergen and Labrador, at Cape Horn, and most abundantly in New South Wales and New Zealand: there are 60 fossil species dating from the trias. The *Terebratellæ* commenced in the lias, and occur in small numbers throughout the cretaceous and tertiary periods, and are the only lamp-shells which attain their climax in recent seas. Five species of *Argiope* occur in the greensand, chalk, and tertiaries. The allied genus *Thecidium* is represented by one species in the carboniferous and one in the triassic system, becomes comparatively common in the secondary period, and dwindles again to a single species in the newer tertiary; this species survives within still narrower limits in the Mediterranean sea. The sub-genus *Terebratulina* is represented by 20 species in the secondary and tertiary formations. *T. striata* of the chalk is so like the recent *T. caput serpentis* as to be with difficulty distinguished from it. Several extinct sub-genera occur in the cretaceous strata, of which the most remarkable are *Trigonosemus* (fig. 11, 1) and *Lyra*, shaped like a violin. The genus *Stringocephalus* (fig. 11, 2) is peculiar to the Devonian strata, and has a large internal loop, and a very prominent cardinal process, forked at the end, and fitting over the central plate of the opposite valve.

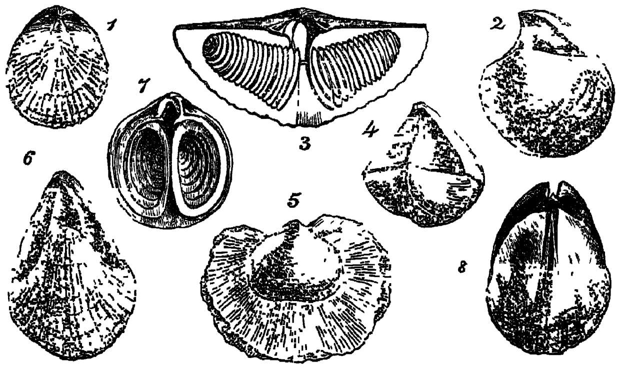

Fig. 11.

Brachiopoda.

1. Trigonosemus Palissyi, Woodw.; *U. Cretaceous*, Ciply.
2. Stringocephalus Burtini, Defr.; *Devonian*, Eifel.
3. Spirifera striata; *Carboniferous*, Britain.
4. Cyrtia trapezoidalis; *U. Silurian*, Dudley.
5. Athyris Roissyi, Lev.; *Carboniferous*, Ireland.
6. Uncites gryphus, Schl.; *Devonian*, Belgium.
7. Atrypa reticularis, L.; *U. Silurian*, Malvern.
8. Pentamerus lævis; *Caradoc S.*, Salop.

The shell of *Terebratula* and some of its allies (*Argiope*, *Thecidium*, *Cyrtia*, and *Spiriferina*) is dotted with minute quincuncial perforations, sometimes visible to the naked eye, as in *T. lima*, but usually requiring a lens of low power.[2]

[1] For the characters of this province and of its classes, see article MOLLUSCA.

[2] They are smallest in *T. carnea*, which Dr Carpenter has figured by mistake for *T. lima* in the *Trans. of the Palæontographical Soc.*

The lamp-shells with sharp beaks and plaited valves have been separated from the *Terebratulæ* under the name *Rhynchonella* (Fisch.) Their shells do not exhibit the punctate structure under a magnifying-glass, and they have no internal skeleton to support their arms, which in the recent species are coiled up spirally, and directed towards the concavity of the smaller valve, like the spires of the extinct *Atrypa* (fig. 11, 7). Of the 3 living species of *Rhynchonella*, one is found throughout the Arctic seas, a second in New Zealand, and the third at the Feejees (?). The fossil species exceed 250, and are found in all parts of the world; those from the palæozoic strata may prove distinct from the rest, since the permian species are known to be provided with large internal processes (*Camarophoria*, King). Casts of these shells are frequently impressed with the narrow and angular pallio-vascular impressions. The extinct genus *Atrypa* differs from *Rhynchonella* solely in having calcareous spires, which are preserved in many instances, and may be cleared to some extent by the application of acid. The foramen is separated from the hinge-line by a *deltidium*; and the interior of the valve is marked by ovarian and vascular spaces exactly as in *Rhynchonella*. The lower Silurian rock contains another genus, *Porambonites* (Pander), as yet imperfectly understood, but having the valves marked externally by impressed dots, which are not perforations. The genus *Pentamerus* occurs in all the strata below the carboniferous limestone, and is remarkable for its great internal partitions, causing the shell to split readily across the middle; and giving rise to deep incisions in those casts of the interior which are so common in the Caradoc sandstone (fig. 11, 8).

The extinct family *Spiriferidæ* are characterized by the possession of internal calcareous spires extending from the centre of the shell outwards (fig. 11, 3). These spires, like the shell itself, are frequently silicified, and may be disengaged from the matrix by the action of acid. At other times the shell is imbedded in soft marl, removeable by careful washing, so as to show the calcareous lamina of the spire fringed with hair-like processes, formerly the support of cirri. In the genus *Spirifera*, the shell has a long straight hinge-line, and the flattened *area* of the larger valve has a deltoid byssal notch.[1] The typical species are characteristic of the palæozoic strata, and have a shell-structure like *Rhynchonella*. The liassic species (*Spiriferina*, D'Orb.), have punctate shells, and the byssal opening is closed (at least in the adult) by a thin arched plate or "pseudo-deltidium." In the sub-genus *Cyrtia* (fig. 11, 4), the hinge-area is ultimately as long as it is wide, and the deltidium is perforated in the centre by a byssal tube; some of the species have a punctate shell. The genus *Athyris* (Dalman), not always easily distinguished from *Terebratula*, has usually a smooth and rounded shell, ornamented with concentric lamellæ or wing-like expansions (fig. 11, 5); the beak is truncated by a round foramen; the hinge-area is obsolete; and the spires are as in *Spirifera*, with the addition of some further complications near the hinge. There are 25 species, mostly from the Devonian and carboniferous rocks. The species of *Retzia* (King) are still more like plaited *Terebratulæ*, but have lateral spires; they range from the Silurian strata to the trias. *Uncites gryphus* (fig. 11, 6), a peculiar Devonian fossil, has a prominent beak, perforated in the young shell by a minute apical foramen; the hinge-area is filled up by a deeply concave deltidium, on each side of which (but only in some specimens) there is a lateral pouch formed by an inflection of the margin of both valves.

The family *Orthidæ* consists of shells with a straight hinge-line, bordered by a flat, narrow area, with a central notch in each valve; the ventral valve is furnished with articulating hinge-teeth, and the dorsal valve has short processes for the support of the oral arms, which appear to have been horizontally spiral (as in *Atrypa*). Between the oral processes there is a central projection for the attachment of the cardinal muscles. Internal moulds of the *Orthis* (fig. 12, 1) exhibit on the ventral side the single attachment of the adductor muscles in the centre, and on

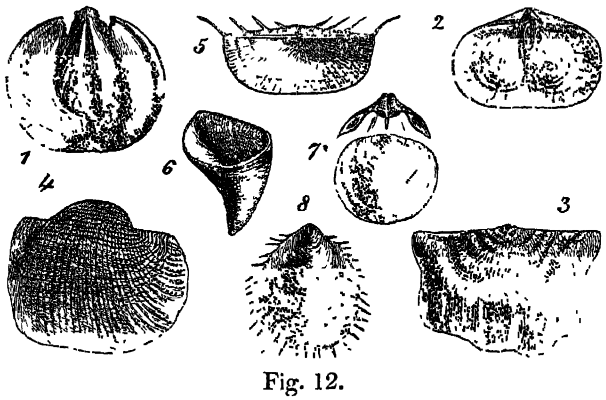

Fig. 12.

each side of it the cardinal muscles; these are surrounded by the punctate ovarian spaces and impressions of the large pallial sinuses. The genus *Orthis* includes 100 species, ranging upwards to the Permian, but it is most abundant in the Silurian rocks. Some of the lower Silurian species have a round foramen in the "pseudo-deltidium," and are called *Orthisinæ* (D'Orb.) Other species in the upper palæozoic rocks have the beak twisted or deformed, probably owing to the attachment of the shell when young (= *Streptorhynchus*, King). In *Strophomena*, Rafin (= *Leptæna*, Dalm.), there is a minute byssal foramen when young, of which no trace exists in the adult; and the deltoid notch is also closed, except the space required to receive the divided cardinal process of the dorsal valve. The oral processes appear to be shifted to the centre of the valve. The shell, when young, is plano-convex, but when it has attained a certain size the valves are bent over to one side or the other, and more or less suddenly. The pallial impressions are the same as in *Orthis*.

The genus *Davidsonia*, peculiar to the Devonian limestones, resembles an *Orthis* attached, like *Thecidium*, by the ventral valve to corals, and sometimes taking the markings of the body on which it grows, like the oyster and *Anomiæ*. The pallial impressions are like those of *Orthis*, and the form of the spiral arms is indicated by prominences which almost fill up the interior of the shell in aged examples. Some indications have been obtained of slender calcareous spires for the support of the arms in this genus; and also in *Koninckia*, a small shell from the trias of St Cassian, in which there are always spiral grooves in the interior of the valves crossed by the impressions of the pallial sinuses.

The anomalous fossil called *Calceola sandalina* (Lam.) is also peculiar to the Devonian limestones. In shape it resembles *Cyrtia*, but has no hinge, and neither foramen nor internal processes, except a row of small projections

[1] The term *deltidium*, applied by Von Buch to this foramen, has, by misconception of his meaning, become constantly used for the plates which partially close it.

Mollusca.

along the hinge-line, and two small lateral groups of ridges in the smaller valve. The interior is punctato-striate, but has no recognisable muscular markings.

The *Productidæ* are altogether palæozoic fossils, and most abundant in the carboniferous limestones. Their valves are concavo-convex, the hinge-line straight, and the interior marked with distinct impressions of the muscles for opening and closing the valves, and simple vascular spaces. There are 60 species of *Producta* found in the upper palæozoic rocks, and having a very wide range in North and South America, and from Spitzbergen to Thibet and Tasmania. Some of them are extremely variable in form; many are armed with long tubular spines, and others completely clothed with short, hair-like processes; they have no hinge-teeth, and the hinge-area is extremely narrow, except in the sub-genus *Aulosteges* of the Russian zechstein. *Producta proboscidea* has its convex valve prolonged into a tube, as if for the constant supply of respiratory currents. The Permian genus *Strophalosia* has its valves articulated by hinge-teeth, and covered with long and slender hollow spines; the shell is attached when young by the umbo of the large valve. *Chonetes* is distinguished from *Producta* by a row of spines along the hinge-margin of the convex valve; it also has a narrow hinge-area with a covered notch, and small hinge-teeth. There are 25 species in the Silurian and carboniferous, usually of small size, and finely striated.

Crania is one of the oldest living types, ranging upwards from the lower Silurian. One of the earliest species appears to have been unattached, and another to have had hinge-teeth. *Crania Ignabergensis*, of the chalk of Sweden, has the valves externally alike, being attached only when very young. The internal markings of *C. antiqua*, and other fossil species, are remarkably grotesque. Lower valves of this genus and *Thecidium* are not uncommon, attached to the tests of sea-urchins, in the chalk; but upper valves are scarce, either detached or *in situ*.

The *Discinidæ* are also ancient fossils, few in number, but appearing in every period. Some of the palæozoic *Discinæ* (= *Orbiculoidea*, D'Orb.) cannot be generically distinguished from the recent species by any characters with which we are as yet acquainted; but others (= *Trematis*, Sharpe) are ornamented with quincuncial punctures, and the casts exhibit indications of diverging internal plates, which imply very considerable difference in the organization of the animal. The genus *Siphonotreta* (Verneuil), peculiar to the Silurian formations, is covered with moniliform tubular spines.

Lingula, which has given its name to the older fossiliferous rock, is another form occurring unchanged in strata of every period. Only 34 species are known, and none of them are very common. The latest British *Lingula* is found in the coralline crag (older *pliocene*) of Suffolk: the nearest living species is as far off as the Philippines. *L. Davisii*, of the "lingula flags" in North Wales, has a pedicle groove in the ventral valve, by which the posterior adductor (or cardinal muscle) must have been divided into two elements, as in the genus *Obolus;* externally it has all the appearance of an ordinary existing shell. *Obolus*, Eichw. (= *Ungula*, Pander) is so abundant in the lower Silurian sandstones of Sweden and Russia as to have given its name to the "obolite grit." In England it occurs only in the upper Silurian of Dudley. The shell is horny in texture, and often stained blue, like the *Lingula*, by the presence of phosphate of iron. In shape it is regularly oval, and differs from *Lingula* in the character of the internal muscular impressions.

CLASS II.—LAMELLIBRANCHIATA.

(Bivalve Shells.)

More than a third part of the known fossil shells are ordinary bivalves (*Conchifera*, Dh.) They amount to nearly 6000, while the recent species scarcely exceed half that number. Nevertheless, it is a group which attains its maximum in the present seas. The genera are seven times more numerous in the newer tertiary than in the oldest geological system; and the number of species found in the entire Silurian series is less than 100, while the chalk contains 500, and the miocene 800. Out of 150 genera, 35 have become extinct, besides numerous sub-genera. The families *Cyprinidæ*, *Astartidæ*, and *Anatinidæ* have passed their maximum; the *Trigoniadæ* are nearly extinct; and the *Hippuritidæ* have no living representatives.

The monomyary bivalves, and others with an open mantle, attain a degree of importance at an early period; and with them some of the burrowing families (*Myacidæ* and *Anatinidæ*); while the highest organized siphonated shells (*e.g.*, *Veneridæ* and *Tellinidæ*), unknown in the older rocks, are most abundant now.

The family *Ostreidæ*, distinguished from the Pectens and *Anomiæ* by resting on the *left* valve, contains two fossil forms. Of these, *Exogyra* resembles an oyster with spiral umbones, directed backwards, or to the left hand; it is an attached shell, characteristic of the cretaceous strata. The genus *Gryphæa* (fig. 14, 1) abounds in the oolites, and is

gregarious, but unattached, the umbo of the larger valve being curved inwards like a claw. A single *Ostrea* occurs in the carboniferous limestone, after which the species become abundant, and are with difficulty distinguishable from the smooth and plaited, or "cocks-comb," oyster of the present day.

Several curious modifications of *Anomia* and *Placuna* have been obtained in a fossil state. *Limanomia* (Bouchard) has ears like *Lima*, and is attached to shells and corals of the Devonian age. *Placunopsis* (M. and L.), found in the oolites, has a transverse ligamental groove, which, like the umbo of the upper valve, is some way within the margin of the shell. And *Carolia* (Cantr.), a tertiary form of *Placuna*, has a byssal plug passing through a foramen like that of *Anomia* when young, but closed in the adult.

Fossil *Pectinidæ* are very numerous. Some of them in the carboniferous limestone (*e.g.*, *P. Sowerbyi*) cannot be distinguished generically from the living Pectens, and retain diverging bands of colour. But the greater part of

Mollusca.

these old species are somewhat aviculoid in form (fig. 13, 1), and their hinge-area is grooved with cartilage-furrows like those of *Arca*. The most beautiful forms occur in the

8. Myophoria decussata, Münt.; *Trias*, S. Cassian.

chalk and greensand, and resemble the recent scallop (*Janira*, Schum.) in the inequality of their valves, but are further characterized by the possession of articulating hinge-teeth like *Spondylus*. These constitute the genus *Neithea* (fig. 14, 2). *Plicatulæ* exist in the trias and oolites, along with shells referred dubiously to *Hinnites* and *Spondylus*. True *Hinnites* (a sub-genus of *Pecten*) are characteristic of the *miocene*. *Spondyli* appear in the greensand and chalk. Some of them (like the so-called "*Plagiostoma spinosum*") are unattached; others resemble the recent deep-water *S. Gussonii*, and have been called "Dianchoræ." The inner layer, including the hinge of these shells, is seldom preserved. *Lima duplicata*, and some other oolitic species, have two ranges of little hinge-teeth, but not like those of the recent species of *Limæa*. The large and smooth or striated Limas of the oolites have been called *Plagiostoma*, a name originally given by Llhwyd.

The pearl-oysters (*Aviculidæ*) are also very abundant fossils: but owing to the frequent repetition of similar forms, it is difficult to determine the genera with any degree of certainty by the aid of external characters alone. The Silurian species mostly belong to the genus *Pterinea* (Goldfuss), and are broadly winged, and have the hinge-area striated lengthwise, and a few diverging hinge-teeth. *Amboncychia* (Hall) resembles *Inoceramus*, and ranges from the Silurian to the carboniferous strata (fig. 13, 3). The Silurian genus *Cardiola* is ridged like a cockle; and *Posidonomya*, which is found in all the palæozoic rocks, is very thin and concentrically furrowed (fig. 13, 2). Many other genera have been proposed whose characters are even more imperfectly understood. *Monotis* (*Salinarius*), one of the common shells of the trias, has no anterior ear. *Pteroperna* (Lycett), an oolitic form, has a winged shell, with numerous small anterior teeth and long posterior laminæ. The genus *Gervillia* (fig. 14, 4), ranging from the carboniferous limestone to the chalk, consists of elongated shells, with several cartilage-pits in the ligamental area. *Bakewellia*, found in the Permian, has an anterior muscular impression like *Arca*. The recent genus *Perna* commenced in the lias or preceding formation, and exhibits great variety of shape. *Pulvinites Adansonii* (fig. 14, 3) appears to have been a Perna with a byssal foramen like *Anomia*; and *Inoceramus* (fig. 14, 5), characteristic of the cretaceous strata and oolites, differs from Perna chiefly in form, the larger valve being sometimes completely involute, and resembling a *Nautilus*. The genus *Pinna*, which appears to belong to this family, although provided with two adductor muscles, occurs fossil in the Devonian and all subsequent strata. Some of the oolitic species, distinguished by the name *Trichites*, are inequivalve and irregular, and attain a thickness of more than an inch, resembling mineral masses of fibrous carbonate of lime.

Amongst the *Mytilidæ* are many Silurian species distinguished by their large, round, anterior muscular scar (*Modiolopsis*, Hall), and others which have a straight hinge-line and plaited valves (*Orthonotus*, Conrad). *Myalina* has the cartilage-groove repeated (fig. 13, 4), and is found in the upper palæozoic rocks. Sometimes the anterior adductor is supported on a shelf, as in the recent *Septifera* and *Dreissenia*. True *Mytili* and *Modiolæ* abound in the oolitic strata. *Dreissenia*, now confined to the rivers of the Aralo-Caspian region, or only naturalized in Western Europe, was represented by many species, and some of large size, in the *eocene* of Hampshire and *miocene* of Vienna.

Fossil *Arcadæ* are far more numerous than the recent shells, and mostly belong to the division *Cucullæa*, of which a single species survives in the Coral Sea. The palæozoic Arks have anterior teeth like *Arca*, and posterior teeth like *Cucullæa*, and differ from both in the reduction of the hinge-area to a narrow tract corresponding with the posterior half only in the recent shells. The casts of Ark-like shells in the Silurian rocks are further distinguished by a deep furrow behind the front muscular impression. These constitute the genus *Ctenodonta* (Salter), which has hinge-teeth like *Nucula*, and a prominent external ligament (fig. 13, 5). Some of the oolitic Arks, with a byssal sinus, and the posterior teeth very long and parallel, form a sub-genus called *Macrodon* (fig. 14, 6). Others, with prominent umbones, teeth like *Nucula*, and a striated ligamental area, form the genus *Isoarca* of Münster (fig. 14. 7). Above 200 species of *Nucula* and *Leda* are known only as fossils, and range through all the rock systems. The palæozoic species are anomalous in form, and when better understood, will certainly be considered distinct as genera. *Yoldia* is a newer tertiary form characteristic of high northern latitudes; and *Solenella* occurs fossil in Patagonia and New Zealand. The problematic genus *Solemya* is supposed to have existed in the carboniferous period. *Pectunculi* appear first in the cretaceous strata, being less ancient than *Limopsis*, which occurs in the Bath oolite. A member of the latter genus found in the Belgian *eocene* has the ligamental area entirely *behind* the cartilage-pit, and is called *Nucunella* by D'Orbigny. The "Stalagmium" of Conrad (= *Myopara*, Lea) is identical with *Crenella* (T. Br.), a sub-genus of *Modiola*, found in the cretaceous and tertiary strata.

The *Trigoniadæ* are represented in the lower Silurian strata by *Lyrodesma* (fig. 13, 6), a shell with several radiating hinge-teeth, striated transversely; and in the upper palæozoics by *Axinus* (fig. 13, 7) and several other imperfectly-known genera. The trias contains true *Trigoniæ* associated with the genus *Myophoria* (fig. 14, 8), which has the umbones turned forwards, and a posterior hinge-tooth. The only member of this family which has yet been found in tertiary strata is the little genus *Verticordia* (Wood) of the crag. No *Trigoniæ* have been met with, although 100 species are known in the secondary rocks, and two are still living on the coasts of South Australia.

Fresh-water mussels (*Unionidæ*), of large size and various form, occur in the Wealden formation, and are not generically distinguishable from recent shells; but those of the

Mollusca.

coal measures and older rocks are extremely problematic, and may even belong to marine genera.

Of the genus *Chama* there is one species in the upper greensand and chalk of England, and another in the London clay. Elsewhere they are more abundant, amounting to thirty species. Closely allied to *Chama* is the *Diceras* (Lam.), of which the remarkable casts attracted attention at an early period (fig. 14, 1). They are found in the coral rag of France and Germany, and resemble the horns of some animal. The shell is attached by the *umbo* of either valve, indifferently, like some of the recent Chamas. The posterior adductor muscle is supported on a prominent ridge (as in *Pachydesma, Megalodon*, and the recent *Cardilia*), which causes a spiral furrow in each horn of the cast. The shells which succeed *Diceras*, in the lower cretaceous strata, have the right valve usually much smaller than the left, and in one instance (fig. 14, 2) it is like the operculum of a spiral univalve. The only British species of this group is *Requienia Lonsdalii*, found in the ironsand of Bowood. In France, and also in Texas, another form occurs, with the attached valve simple and conical, like a Hippurite. The ligamental groove is straight, and the umbo of the free valve marginal.

These shells are so intimately allied to the *Hippuritidæ*, that *Requienia* has been frequently included with them in the apocryphal order "Rudista." The members of the Hippurite group are attached and gregarious, like oysters, often occurring in great numbers, and filling large tracts of rock. Their valves are different in structure and sculpturing, and are articulated by two prominent teeth above and one below; the cartilage is internal, but there is a conspicuous ligamental furrow outside. There are nearly 100 species characteristic of the cretaceous strata, and especially of the lower chalk, or "hippurite limestone." Only one species (*Radiolites Mortoni*) is found in England; the rest are from the West Indies, Southern Europe, Algeria, and the East. The form which approaches nearest to *Chama* is the little genus *Caprotina* (fig. 15, 7), whose upper valve has a marginal *umbo*, but is in other respects like a miniature *Radiolite*. *Caprina* (D'Orb.) has the free valve perforated by canals which open in the inner margin, and in *Caprinella* the outer lamina of both valves possesses this structure. One valve is sometimes spiral (fig. 15, 6), and partitioned off internally by numerous *septa*,

like the water-Spondylus, but so regularly as to resemble the chambered shell of a *Nautilus*. In the *Radiolite* (fig. 15, 5), both valves are conical, and the *umbo* of the free valve (marginal in the very young shell) becomes central in the adult. The structure of the hinge is modified by the absence of any spirality in the valves, but is essentially the same as in *Caprotina* and *Diceras;* the prominent teeth of the upper valve support curved plates for the attachment of the adductor muscles, which become continually more undercut in the course of their growth. In *Hippurites*, the anterior muscular plate projects horizontally, the posterior vertically, like a third tooth, for which it has been mistaken. In this genus there are two longitudinal inflexions of the outer shell-wall beside the ligamental furrow, one corresponding to the posterior muscular plate, the other (or third) apparently a *siphonal* inflexion like that in *Trigonia* and *Leda* (fig. 15, 4).

The cockle-shells (*Cardiadæ*), as they have a world-wide distribution now, had a corresponding range in *time*, and are found in all strata from the Silurian upwards. The commonest fossil type of *Cardium* is ribbed concentrically on the sides, and radiately on the posterior slope, a style of ornament almost unique amongst the 200 recent species. The Caspian cockles, distinguished by a *sinus* in the pallial line, appear to have inhabited the Aralo-Caspian region almost from the middle tertiary period; the hinge-teeth are reduced to one (*Monodacna*) or two (*Didacna*) in each valve, and are sometimes quite wanting even in the young shell (*Adacna*, Eichw.) *Lithocardium aviculare* (fig. 16, 7) is a characteristic shell of the Paris basin, and appears to have spun a byssus, like the fry of some recent cockles; it also resembles the oriental *Tridacna*, of which a species is found in the *miocene* of Poland. The genus *Conocardium* (fig. 13, 8) of the upper Silurian and carboniferous systems is remarkable for the prismatic cellular structure of its shell, and the truncation of the posterior (?) side of the valves, which are furnished in some species with a slender siphonal process.

The *Lucinidæ*, allied to the cockles in their hinge-structure, are also plentiful in the fossil state, and have as wide a range. They are usually recognisable, even when in the condition of internal casts, by their circular form and the oblique ridge on their disk. Casts of *Lucina* also exhibit the peculiar narrow outline of the anterior adductor detached from the pallial line. *Cryptodon, Diplodonta, Kellia*, and *Pythina* are found in the eocene tertiary. *Corbis*, under the sub-generic form of *Sphæra*, commences in the trias; another modification, found in the oolites and chalk (*Unicardium*, D'Orb.), is edentulous; and *Tancredia* (Lycett), a compressed triangular shell, with a dentition like *Corbis*, is frequent in the lias and oolite.

The fresh-water *Cycladidæ* are represented in the *Wealden* and *eocene* by many species of *Cyrena*, mostly of small size. The recent *Corbicula fluminalis* of eastern rivers is a common fossil of the pliocene tertiary in England and Sicily.

The *Cyprinidæ* and *Astartidæ* are more abundant as fossil shells, and had a wider range of old than at the present day. Nearly 100 species of *Cyprina* have been catalogued, commencing in the trias; the dentition of the older species is, however, somewhat peculiar. The *Isocardiæ* are almost as numerous, and have the same range, but many of the fossil Isocardia-looking shells are really related to the *Anatinidæ*. A yet higher antiquity has been assigned to *Cypricardia*, a genus now very scarce and difficult to obtain, on account of its habit. The palæozoic *Pleurophorus* (fig. 13, 9) is distinguished by the prominent ridge behind the anterior muscular impression; and *Megalodon* (J. Sby.), by the plate supporting the posterior adductor. This genus is represented in the oolites by *Pachyrisma* (fig. 16, 1), and in the tertiaries and modern seas by *Cardilia*.

The genus *Astarte*, now limited to a dozen species in the North Atlantic and Arctic seas, has an almost world-wide geological distribution, and counts 200 species in

Mollusca.

D'Orbigny's catalogue, commencing with the *lias* period. *Crassatella*, now almost a southern form, is common in the cretaceous and tertiary strata of Europe. Closely allied to *Astarte* is the extinct genus *Opis* (fig. 16, 3), of which there are 42 species in the secondary series; and *Cardinia* (fig. 16, 2), characteristic of the lias and oolites.

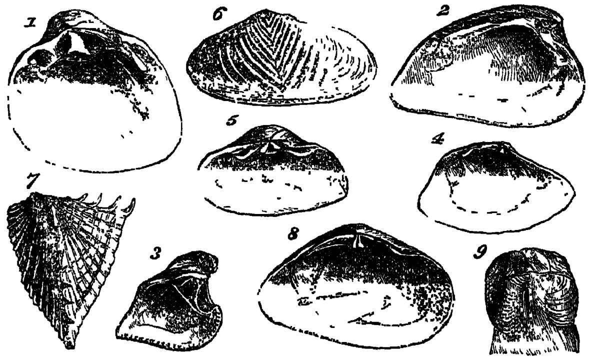

Fig. 16.

2. Cardinia hybrida, Sby.; *Lias*, Gloucester.
3. Opis tumulatus, Mill.; *Inf. Oolite*, Bayeux.
4. Tancredia securiformis, Dkr.; *Lias*, Saxony.
5. Sowerbya crassa, D'Orb.; *Oxfordian*, Ardennes.
6. Goniomya scripta, Sby.; *Kelloway rock*, Wilts.
7. Lithocardium aviculare, Lam.; *Eocene*, Paris.
8. Grateloupia irregularis, Bart.; *Miocene*, Bordeaux.
9. Teredina personata, Lam., *Eocene*, Bogna.

The so-called Unios of the coal measures (*Anthracosia*, King) are probably members of this group. One hundred species of *Cardita* (including *Venericardia*) are found in the secondary and tertiary strata; of the 50 recent forms, one only is Arctic, and this occurs in the glacial deposits of England. The allied genus *Myoconcha* is characteristic of the older secondary rocks, and *Hippopodium* of the lias.

The *Veneridæ* are pre-eminently characteristic of the tertiary and present period. Some obscure species of Venus are found in the oolites: *Cytherea* occur in the greensands; *Artemis*, *Trigona*, *Lucinopsis*, *Venerupis*, and *Tapes* appear in the middle tertiary; *Petricola* in the eocene. The only extinct form is *Grateloupia* (fig. 16, 8), which differs but little from *Trigona*.

The Mactras and Tellens are also comparatively modern groups; most of the supposed oolitic species belong to *Lucinidæ*, except *Sowerbya* (fig. 16, 5), which has a pallial sinus, and is found in the oolites of Malton and Portland. *Psammobiæ* and *Mesodesmæ* occur in the greensand; *Donax* and *Syndosmya* in the eocene; *Gastranæ* and *Lutraria* in the *miocene*. *Lutraria rugosa*, still living on the coast of Portugal, is fossil in the raised beaches of Sussex.

The oldest forms of razor-fish (*Solenidæ*) are those with the transverse internal rib (*Solecurtus*), which occur in the neocomian, whilst true Solens and *Glycimeris* appear first in the eocene strata. The genus *Mya*, as now restricted to the species resembling *M. arenaria*, are only met with in the newer tertiary. *Corbula* ranges upwards from the lower oolites; *Neæra* appears in the upper greensand; and *Thetis* (=*Poromya*, Forbes) in the neocomian.

Above 100 species of *Panopæa* (a genus essentially like *Mya*) have been obtained from oolitic and tertiary strata in all parts of the world. They are with difficulty distinguished from those equally numerous forms of *Anatinidæ* which have been associated with *Pholadomya* on account of the tenuity of their finely-granulated valves; they constitute the genus *Myacites* (Bronn), and occur in all the palæozoic and secondary rocks; some of the oolitic and cretaceous species are distinguished by V-shaped furrows (fig. 16, 6). Still more numerous are the fossil forms of *Pholadomya*, which range upwards from the lias, but are reduced to a single species now living in the Caribbean seas. Shells with the umbones fissured like *Anatina* also occur in the oolites. *Pandora* first appears in the older tertiary. Amongst the extinct genera referred to this family are the Silurian *Grammysia* (fig. 13, 10), with valves folded transversely; the carboniferous *Edmondia* (fig. 13, 11), with large oblique cartilage plates; and *Cardiomorpha*, shaped like *Isocardia*; and the oolitic *Ceromya* (Ag.), which also resembles the heart-cockle in form. *Cercomya* is an oolitic *Anatina*, with the posterior end of the valves much attenuated.

The genus *Gastrochæna* appears in the lower oolites; and casts of its burrows are frequently preserved after the decomposition of the coral in which they were made. *Clavagella* dates from the upper greensand, and *Aspergillum* from the *miocene*. *Saxicava* is found in the newer tertiary and raised beaches of Northern Europe; and the great species commonly called "*Panopæa*" *Norwegica* is a characteristic fossil of the newer pliocene of Britain and Greenland.

The Pholades and ship-worms appear first in the oolitic strata. Forms resembling the recent *Martesia striata* have been discovered in fossil wood of the lias and Speeton clay. *Jouannetia* (Desm.) was first known as a miocene fossil; and *Pholas* occurs in the older tertiary. Extinct species of *Teredo* are found in the silicified wood of the greensand of Blackdown and in the fossil palm-fruits of Brabant and Sheppy. The drift-wood of the London clay is usually perforated by the ship-worm, and also by an extinct form (*Teredina*, fig. 16, 9), which resembles *Martesia* in possessing an umbonal shield: when adult, it not only closes the anterior pedal opening, but also cements its valves to the shelly lining of its burrow, like an *Aspergillum*. Specimens have been obtained in which the whole interior of the valves and tube had been excessively thickened towards the close of life by successive layers of shell.

Class III.—GASTEROPODA.

Fossil univalves—the remains of spiral and limpet-like shells—are not wanting in any but the very oldest fossiliferous rocks ("lingula flags"). From the lower Silurian, where less than 100 species, referable to scarcely more than 10 genera, are found, they increase in number and variety slowly and regularly up to the newer tertiaries, which have afforded ten times as many genera and twenty times as many species. The total number of fossil marine univalves is less than 6000; the recent exceed 8000; and although we may expect to discover more new fossil species than recent, yet it is evident the group of univalves has only now attained its maximum development.

Between the extinct and living air-breathers the numerical discrepancy is still greater. About 300 land-snails, and half as many fresh-water *Pulmonifera*, are enumerated in the fossil catalogues; but the greater part of these are recent species, and the whole bears no proportion to the number of living land-snails, which exceed 4000. That many more have formerly existed is indicated by the fact, that the fossil land-snails of the older tertiaries of Europe are entirely different from their living successors, and most nearly represented at the present time in the West Indies and Brazil. The generic forms peculiar to oceanic islands (remains of old continents) are more numerous than those of the mainlands, as if this order had once been more important. But the circumstances favourable to their petrifaction must have been of such rare occurrence as to preclude the probability of attaining more than the scantiest information concerning them.

From the large and proportional number of living Gas-

Mollusca.

teropods, and the great amount of information which has been obtained of late years respecting their structure and habits, it might be expected that the affinities of the fossil univalves would be easily worked out, and their indications fully interpreted. Such, however, is not the case. Univalve shells present no internal markings, easily accessible

like those of bivalves, and exhibiting the essential characters of the soft parts; and their external forms are often so overlaid with ornament, and disguised by *mimetic* characters, as to mislead upon a first examination. Shells of any family may be limpet-shaped, or turreted, or discoidal, plain or ornamented. It is more desirable to ascertain whether they have been nacreous or porcellanous; whether the apex (or *nucleus*) presents any peculiarities; and if operculated, whether the operculum was few-whirled or multispiral.

The earlier describers of fossil univalves unhesitatingly recognised many familiar recent genera, even in the older rocks. But their "Melanias" were marine shells; the supposed *Buccinum* had no notch; the *Solaria* were pearly; the *Neritas* assumed, when adult, the irregular aperture of *Pileopsis;* the Naticas had non-spiral opercula; and the *Maclurea* was figured upside down.

The more closely palæozoic univalves are examined, so much the more do they appear to differ from ordinary recent types; and the search for allied forms has to be conducted amongst the rare and minute and least understood of recent shells.

Nucleobranchiata.—Those fossil univalves, which in their symmetry resemble the *Nautilus*, but are unfurnished with air-chambers, have been compared to the recent *Heteropoda* (or *Nucleobranchiata*, Bl.), and especially to that division typified by the tiny *Atlanta*, in which the animal can withdraw itself completely into its shell, and close the aperture with an operculum. The genus *Porcellia*, characteristic of the carboniferous age, has a discoidal shell, with a spiral nucleus projecting, as in *Atlanta*, from the right side; the whirls are exposed, and marked with a narrow band along the back, ending in a deep slit (fig. 17, 6). Another genus (*Bellerophon*) resembles the recent *Oxygyrus* in its more globose form, with a similar narrow umbilicus on either side (fig. 17, 7); sometimes the shell is thin and the aperture expanded, like a trumpet, whilst other species are globular and solid; the former may have been tenanted by large animals living at the surface of the open sea, the latter seem to have been more adapted to protect their owners crawling over the bottom, for it can scarcely be insisted that all were necessarily floaters on account of their organization. The species of *Bellerophon* are numerous in all the palæozoic rocks, and some of the smaller kinds appear to have been gregarious: those with disconnected whirls have been called *Cyrtolites* (Conrad.) The *Bellerophina* of D'Orbigny (fig. 18, 11) is a minute shell found in the gault. The other division (*Firolidæ*) consists of Mollusks in which the shell is wanting or rudimentary, and small compared with the bulk of the animal. A single species of the genus *Carinaria* has been found in the middle tertiary of Turin.

Strombidæ.— The Strombs, with their massive shells, nevertheless, resemble the fragile Heteropods in some respects. They have the same lingual dentition, and the same carnivorous habits; and though living on the sea-bed, they rather leap than glide, having a narrow sole and a deeply-divided operculigerous lobe. Characteristic of the warmer zones of existing seas, they are only found fossilized in the newer tertiary strata of countries south of Britain; but there is a group of little shells related to the recent *S. fissurellus* in the older tertiaries of London, Paris, and America, to which Agassiz has given the name *Rimella.* The allied genus of scorpion-shells (*Pterocera*), now peculiar to eastern seas, has been described as occurring fossil in the secondary strata of Europe; but the extinct species appear to be more nearly related to *Aporrhais.* This genus, now confined to the western shores of Europe, occurs in all the tertiaries, and is represented in the secondary rocks by many remarkable forms. Some have been separated under the name *Alaria;* and to this group the so-called *Pterocera Bentleyi* may perhaps be referred (fig. 18, 2). *Rostellaria* and *Serapis* (or *Terebellum*), now peculiar to the Red or eastern seas, are conspicuous fossils of the European eocene, at which time their range extended to America. Some of the ancient Rostellarias have the outer lip enormously expanded, as in the *R. ampla* (*Hippocrena*) of the London clay. In the oolites and chalk there are slender fusiform shells (*Spinigera*, D'Orb., fig. 18, 1) with spines on the sides of the whirls, as in some recent *Runellæ.*

Muricidæ.—The great family of whelks, by far the most

important group of living sea-shells, is scarcely of higher antiquity than the eocene tertiary. The *Purpurina* of the oolites (fig. 18, 3), and *Columbellina* of the chalk, are

extinct genera somewhat resembling *Purpura* and *Columbella*. But since the so-called "cones" of the oolites have proved to be *Tornatellæ*, it may not be unreasonable to distrust these other presumed affinities. The huge univalve of the chalk, which Sowerby called a *Dolium*, has been described as a *Pterocera* by D'Orbigny. In the tertiaries siphonated univalves abound, and are mostly referable with certainty to recent genera. The only marked change consists in the comparative abundance of some scarce existing forms, and the absence or rarity of many now most conspicuous. Moreover, the geographical distribution of the genera has undergone a great change since the close of the eocene period. This change is most noticeable in the cold-temperate zone, and is evidently the result of altered climate. The northern seas must ever have been inclement, and the tropical seas always tropical; but the latitude of England being most liable to vicissitudes of climate, might be expected to show the greatest variety, and the most complete and rapid alterations of organic

life. In the London clay are found many species of *Clavella, Typhis, Mitra, Pseudoliva, Oliva*, and *Ancillaria;* and some extinct forms (*Leiostoma* and *Strepsidura*) related to *Fusus*. The middle tertiary, wanting in England, but largely developed in Central and Southern Europe, also contains many genera belonging now to warmer latitudes, and many species still living in the south. In the newer tertiaries of Europe these southern forms disappear, and are gradually replaced by others of an opposite character (*Trophon, Neptunia*, and *Trichotropis*), now inhabiting the Arctic and boreal coasts. The entire number of fossil *Muricidæ* amounts to 1000, or about half as many as the recent. The older tertiaries of England also contain species of *Triton, Cassidaria, Cancellaria*, and *Pyrula*, shells (now foreign to our seas), which have formerly been included in this family. As regards bulk, there are no fossil species of *Fusus, Triton*, and *Cassis* (or *Strombus* and *Voluta*) to compare with those of the present day.

Conidæ.—The Cones and Pleurotomas appear first in the chalk, and are abundant in the eocene, accompanied by an intermediate form (*Conorbis*, fig. 19, 3), and another extinct sub-genus (*Borsonia*, fig. 19, 4), in which the column is plaited, as in *Mitra*. The genus *Terebra* is commoner in the miocene.

Volutidæ.—The Volutes also appear as cretaceous fossils in Europe and Southern India; they are very abundant in the London clay, and one occurs in the English crag. The ancient species are mostly distinguished by their spires being acute, as in *Mitra* (fig. 19, 5), a peculiarity only found in one very rare living (?) species, dredged from a bed of dead shells in 132 fathoms water (792 feet) off the Cape. The crag Volute resembles the Magellanic form. *Cymba olla*, the only living European Volute, is a fossil in the *pliocene* of Majorca.

Cypræidæ.—The Cowries form another group of subtropical shells once common in the temperate zone. Several large species are found in the London clay, most nearly related to the southern *Cyprovula;* whilst the crag contains only members of the sub-genus *Trivia*, one of which still lives on our coast.

The round-mouthed shells (*Holostomata*), whether animal-feeders or vegetarians, make a conspicuous figure amongst the fossils of an earlier period than that in which the last group began to flourish. The carnivorous *Naticidæ* and *Pyramidellidæ* are represented in the palæozoic strata by *Naticopsis, Loxonema* (fig. 17, 1), and *Macrochilus* (fig. 17, 2). The violet-snail (*Ianthina*), so unlike any other existing shell-fish, seems related to the Silurian *Scalites, Raphistoma*, and *Holopea*. Shells like *Scalaria* and *Solarium* occur in the trias and oolites associated with *Chemnitziæ* (?) of extraordinary size, and species of *Eulima* and *Niso*. These families of shells and the *Cerithiadæ* are more abundant fossil than recent, the known numbers being 1500 extinct and 900 living forms. *Solaria*, with disconnected whirls and pyramidal opercula (*Bifrontia*, Dh.), are common in the eocene tertiary, and a single living species (*B. zanclæa*) has been discovered by M'Andrew.

Amongst the tertiary Naticas are many with an oblique aperture and peculiar perforation (*Globulus*, J. Sby., = *Ampullina*, Bl.), and others with prominences on the pillar (*Deshayesia*, fig. 19, 6.) The *Nerinæas* of the oolites are remarkable for the spiral ridges (like the "worm" of a screw) winding round their interior, and giving rise to the variety of singular patterns seen in sections (fig. 18, 4). A similar structure exists in the recent "telescope-shell" (*Terebralia*). The fresh-water univalves of the Wealden and older tertiaries differ but little from their recent congeners of the genera *Paludina, Potamides, Melania*, and *Melanopsis*. Fossil *Turritellæ* are of doubtful occurrence before the tertiary; the Silurian species have the peristome complete (*Holopella*, M'C.); another form (*Proto*, fig. 19, 7) is characteristic of the miocene.

The bonnet-limpets (*Calyptræidæ*) are common in the old rocks, which also contain a few species of *Chiton* and shells like *Dentalium*. Fossil *Trochidæ* are very numerous, but hitherto many *Litorinidæ* have doubtless been included with them. Perhaps no true *Turbo* is known from strata before the cretaceous. The *Euomphali* (fig. 17, 4), which characterize the older rocks, have multispiral calcareous opercula, like the recent *Cyclostrema* (= *Adeorbis*). The genus *Maclurea* (fig. 17, 9), which has been regarded as a "left-handed" *Euomphalus*, is probably very different; it has a thick shelly operculum, sinistrally spiral, and furnished with an internal process, as the Nerites are; the spire is sunk and concealed, whilst the whirls are exposed on the flattened under-side; it occurs in the older Silurian rocks of Scotland and North America. One common feature of the palæozoic spiral shells is their tendency to become irregular towards the conclusion of their growth: in *Serpularia* (= *Phanerotinus*, Sby.), the whirls are all disunited; in *Scoliostoma* (fig. 17, 3) and *Catantostoma* the aperture is expanded. Some small oolitic shells have a thickened peristome (*Crossostoma*, fig. 18, 5), like the recent *Lietia*, which commences in the older tertiary. A large proportion of the trochiform fossil shells have their whirls, whether round or angular, marked by a peculiar band, terminating in a deep slit

Mollusca.

at the aperture; most of these were solid nacreous shells belonging to the genus *Pleurotomaria*, of which but a single species survives; others in their slenderness resemble *Turritellæ*, and have been named *Murchisonia* (fig. 17, 5). The carboniferous shell called *Polytremaria* has a row of holes in place of a slit; and the Silurian *Tubina* (fig. 17, 8) has three rows of tubular spines. The *Cirrus* of the inferior oolite is a reversed shell with one row of similar ornaments; and *Trochotoma* (fig. 18, 6) has a perforation near the margin of the aperture, which is carried onward as the shell grows. *Scissurella*, which is always diminutive and not pearly, makes its first appearance only in the newer tertiary. *Haliotis* occurs in the miocene of Malta. The *Neritidæ* appear in the oolites: besides true Nerites, there are *Neritomæ* (fig. 18, 7), with a channeled outer lip: *Pileolus*, which is perfectly limpet-like above (fig. 18, 8); and *Neritopsis*, with its angular columellar notch most distinctly marked. Key-hole limpets (*Fissurellidæ*) occur as early as the carboniferous period, but are very scarce at first, and never become numerous. The oolitic *Rimula* is a minute shell supposed to be related to a very rare living species. Ordinary limpets (*Patellidæ*) of unequivocal form are found in the Bath oolite, but are afterwards less plentiful, and almost disappear from the tertiaries; M. D'Orbigny regarded them as generically distinct, but employed for them a name (*Helcion*, Mont.) synonymous with *Patella*.

Pulmonifera.—The existence of air-breathing snails in the palæozoic rocks is indicated only by the somewhat problematic *Dendropupa*, discovered by Sir C. Lyell in a coal tree of Nova Scotia. The Purbeck limestone contains a modern-looking *Physa;* and other species of extraordinary size are found in the older tertiary of France, and also in Central India, where the genus does not exist at the present day. The fresh-water eocene of the Isle of Wight and Paris has afforded many species of *Limnæa* and *Planorbis;* a *Glandina* rivalling in size the *G. truncata* of South Carolina; a *Cyclostoma*, with a sculptured operculum like the *Cyclotus Jamaicensis;* and an elongated species of the section *Megalomastoma*, which is now living in both East and West Indies. At Hordle has been found the little *Helix labyrinthicus*, still living in Texas; and in the south of France occur representatives of the Brazilian genera *Megaspira* and *Anastoma* (fig. 19, 9). In the *miocene* is found another genus (*Ferussina*, fig. 19, 10) resembling the lamp-snail, but supposed to be operculated. The *Pulmonifera* of the English *pliocene* are in a few instances extinct, at least in England; nearly all are still living here, but more or less abundant now than they were in the times of the mastodon and elephant. The extinct land-snails of the Atlantic islands Madeira and Porto Santo are associated with remains of many recent species occurring in numbers which have relatively altered, telling the same tale of gradual changes, affecting some species prejudicially, but favourable to the increase of others. The fossil land-snails of St Helena were supposed by Mr Darwin to have become finally extinct only in the last century, owing to the destruction of the native woods by the instrumentality of goats and swine.

Tectibranchiata.—The families typified by *Tornatella*, *Ringicula*, and *Bulla* played a more important part in the secondary and tertiary periods, but their affinities have been seldom understood. The cone-like *Acteonina* appeared in the carboniferous rocks, and attained a remarkable development in the lias (fig. 18, 10). They were succeeded by the *Acteonellæ*, with a plaited columella, in the cretaceous strata; and by *Volvaria* (fig. 19, 11) in the eocene. The diminutive *Ringiculæ* of our seas were preceded by large species of the same genus in the tertiaries, and by *Cinulia* (fig. 18, 9), *Globiconcha*, and *Tylostoma*, in the cretaceous strata. The genus *Varigera* has varices recurring twice in each whirl, like *Eulima;* and *Pterodonta* is winged like *Strombus*.

Mollusca.

Pteropoda.—The fragile shells of *Hyalea* and *Cleodora* are found in the newer tertiary of Italy, with *Vaginella* (fig. 19, 12), a form allied to *Cuvieria*. But the occurrence of *Pteropoda* in the older rocks is attended with considerable obscurity. The shells called *Theca* are slender and conical; *Pterotheca* has a wing-like expansion; and *Conularia* (fig. 17, 10) is a four-sided sheath, with the apex partitioned off, as in the recent *Cuvieria*. If really pteropodous, these shells are the giants of the order.

CLASS IV.—CEPHALOPODA.

Order 1.—TETRABRANCHIATA.
(*Nautiloid Cephalapoda*.)

Of the lower group of Cephalopods, possessing chambered shells similar to the pearly *Nautili*, there are 1400 extinct species, belonging to above 30 genera, while 5 or 6 species alone exist in modern seas. These fossils resemble the *Nautilus*, and differ from the dibranchiate *Spirula* in the structure of their shell, which is composed of two layers, the outer porcellanous, the inner pearly; whereas the *Spirula*—an internal shell—is entirely nacreous. They also agree with the *Nautilus* in the relative capacity of their last chamber, which seems obviously large enough to contain the whole animal. Moreover, it appears, from the position of the siphuncle and the form of the aperture, that these shells were revolutely spiral, or coiled over the back of the animal, and not involute like the *Spirula*. No traces of fossil *sepia* or horny claws have been found associated with them, nor any indications of dense muscular tissue, even in the same matrix which has preserved so completely the mummy cuttle-fish. By their form and size they were ill adapted for rapid locomotion, and must have depended for safety on the shelter afforded by their solid shell. The discoidal *Ammonites* attained a diameter approaching 3 feet, and the straight-shelled *Orthocerata* were sometimes not less than 6 feet in length. These latter must have lived habitually in a position nearly vertical; whilst the discoidal genera would creep over the sea-bed with their air-chambers above them, like a snail-shell reversed. The *Ammonites* appear to have been provided with an *operculum*, more secure than the "hood" of the Nautilus, but, like it, composed of two elements united by a straight suture. These opercula, frequently mistaken for bivalve shells, have a porous structure altogether peculiar, and are frequently sculptured on their outer convex surface; whilst their concavity exhibits only lines of growth (fig. 21, 7.) Special forms are associated, in all localities, with particular species of ammonite; and their size is adapted exactly to the specimens in which they are found. Calcareous mandibles occur in all the secondary strata, but not (hitherto) in such numbers or circumstances as to imply that they belonged to any other genus beside the true *Nautilus*. They are of two forms: those corresponding to the upper mandible (fig. 21, 8) have been called *Rhyncholites* (*Palæoteuthis* and *Rynchoteuthis* of D'Orbigny); whilst the lower mandibles constitute the "genus" *Conchorhynchus* of De Blainville (fig. 21, 9). The arms of the extinct Tetrabranchs may have been organized like those of the Nautilus, but were probably less numerous in the genera with slender shells, and in those early forms with a small many-lobed aperture. The length of the body-chamber is greatest when its diameter is least; and the prominent spines which ornament the exterior are partitioned off internally by a nacreous lamina, indicating considerable motion of the animal in its shell. When the outer shell of the fossil is removed by decomposition or the hammer, the margins of the internal *septa* (or parti-

tions of the air-chambers) are exposed. These marginal lines are called *sutures.*

The chambered shells may be divided into two principal groups: those with simple sutures, like the recent Nautilus; and the Ammonitidæ, in which the margins of the septa are lobed and foliaceous. In the former the siphuncle is central or internal (*i.e.*, at the margin next the spire); in the latter it is external (*i.e.*, at the *back* of the shell, but *ventral* as regards the animal). There are, however, *Nautili* with lobed sutures (*Aturia*, Bronn, fig. 19, 1); and some with an external siphuncle (*Cryptoceras*, D'Orb.) And on the other hand, the sutures of the Ammonite are at first very slightly lobed, and become progressively more complex; so that specimens of the *same species* have been referred to three genera—*Goniatites*, *Ceratites*, and *Ammonites*—according to their age.

With the exception of *Goniatites*, the *Ammonitidæ* are peculiar to, and co-extensive with, the secondary strata; while the *Nautilidæ*, with the exception of *Nautilus* and *Aturia*, are confined to the palæozoic rocks. But the so-called palæozoic *Nautilidæ* exhibit peculiarities suggesting very wide differences. It has been proposed to associate the greater part of them with the *Orthocerata* as a distinct family, but at present the data are defective. Like the *Ammonitidæ*, their shells assume almost every conceivable form and curvature, and the genera founded on these characters are very ill defined.

The simplest form of *Orthoceras* is like a *Nautilus unrolled;* and *Lituites* (fig. 20, 2) is the same with the apex spiral. Some of the carboniferous *Nautili* have a square back, and the whirls either compact or open in the centre (fig. 20, 1); whilst the last chamber is more or less disunited. The species with the whirls quite disunited constitute the genus *Trigonoceras*, M'C. (=*Nautiloceras*, D'Orb.) The Silurian genus *Trochoceras*, Barr, is a spiral Nautilus. *Clymenia*, a characteristic Devonian fossil, has angular sutures and an internal siphuncle; it may perhaps be coiled up ventrally like the *Spirula*. The tertiary shell called *Nautilus zic-zac* (*Aturia*, Br., fig. 19, 1, 2), which is so widely distributed in Europe, America, and India, has a siphuncle nearly marginal when young, but gradually becoming more central in the adult: it has no special relation to *Clymenia.*

Those species of *Orthocerata* in which the aperture is contracted form the genus *Apioceras*, Fischer (=*Poterioceras*, M'C.), or when also curved, the *Oncoceras* of Hall. In Barrande's genus *Ascoceras* (fig. 20, 9) the shell is flask-shaped, the chambered and siphunculated apex being apparently deciduous; the aperture is contracted, and the air-chambers occupy only the dorsal half of the shell. In *Phragmoceras* (fig. 20, 7), the shell is slightly curved to the ventral side, and the aperture is remarkably contracted, the opening for the respiratory funnel being nearly distinct from the cephalic aperture. In *Cyrtoceras* the curvature is dorsal.

In some other members of this family the siphuncle attains a remarkable size or extraordinary complexity.

In *Camaroceras* (fig. 20, 4), the siphuncle is lateral, quite simple, and equal to half the diameter of the shell. Casts of these great siphuncles were called "Hyolites" by Eichwald; they frequently contain small shells of *Orthoceras*, *Bellerophon*, and other genera. In some species the siphuncle is strengthened internally by repeated layers of shell, or partitioned off by a succession of funnel-shaped diaphragms; these constitute the genus *Endoceras* of Hall. The same author has given the name *Discosorus* to a fossil which is evidently the siphuncle of some very delicate and perishable chambered shell (fig. 20, 6). In those *Orthocerata* with siphuncles most nearly resembling the *Discosorus* they diminish rapidly towards the last chamber. Perhaps the most remarkable fossil of this group is the

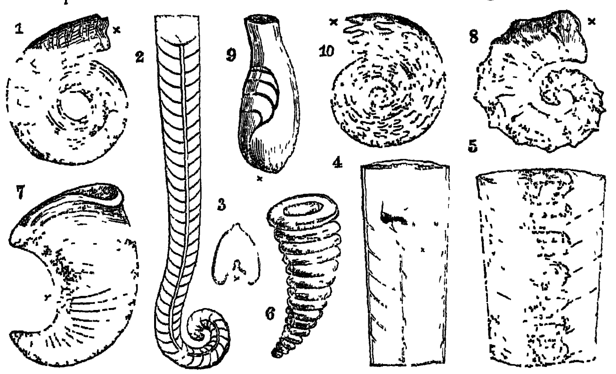

Fig. 20.

10. Goniatites, Henslowi, Sby.; *Carboniferous*, Asturias.

Huronia (fig. 20, 5), found in the upper Silurian limestone of Drummond Island. Siphuncles 6 feet in length and 1½ inch in diameter, were seen by Dr Bigsby in the cliffs; they are silicified, and stand out in bold relief from the matrix, but are unaccompanied by any vestige of the shell, except in one or two instances, where the septa are faintly indicated by coloured lines. They are sometimes overgrown with coral, and were evidently so durable as to remain on the sea-bed long after the shell itself had decayed. The joints of the siphuncle are swollen at the upper part, and the interior is filled with an irregularly-radiated structure, apparently produced by the plaiting and calcification of the lining membrane. This structure also exists and is very regular in the siphuncle of the Devonian *Orthoceras trigonale*, and in the shells referred to *Gyroceras* by D'Orbigny (fig. 20, 8); also in *Actinoceras*, a sub-genus of *Orthoceras*, discovered by Dr Bigsby, and described by Stokes (*Geol. Trans.*, vol. i., 1825). The plication of this interior structure takes place in segments corresponding to the septa, and meeting in the centres of the siphuncular beads, leaving spaces or foramina for the passage of blood-vessels to the lining membrane of the air-chambers.[1] The vascularity of the latter is well shown in the impression of septa on the fine mudstones of the Ludlow rock, often mistaken for *Spongaria*, which they somewhat resemble.

Towards the conclusion of its growth the air-chambers of the *Orthoceras* frequently become shallower, and the siphuncle diminishes in size. These indications of changed or diminished energies are accompanied by a diminution or disappearance of the internal radiated structure in the last part of the siphuncle.

In *Orthoceras bisiphonatum* (*Tretoceras*, Salter) the body-chamber is prolonged in the form of a marginal lobe, simulating a second siphuncle.

The genus *Bactrites* of Sandberger also resembles an *Orthoceras* with single-lobed sutures.

Ammonitidæ.—In the second division or family of chambered shells—those with lobed sutures and a marginal siphuncle—we find a similar series of forms,—straight, spiral, and discoidal, but more varied and more highly ornamented.

One large genus (*Goniatites*, fig. 20, 10) is found in the Devonian, carboniferous, and triassic strata, and permanently resembles the youngest form of the *Ammonites*,

[1] In the carboniferous species of *Actinoceras* (*e.g.*, *A. giganteum*), these foramina form a cross on the ventral side of the siphuncle.

having the sutures lobed but not foliated. They seldom exceed 6 inches in diameter, and are usually very much smaller.

6. Ancyloceras.
7. Trigonellites.
8. (Rhyncholites hirundo), upper mandible of Nautilus arietis, Rein., *Muschelkalk*
9. Lower mandible (Conchorynchus avirostris.)

The whirls are most frequently concealed to some extent, and often marked by cross furrows or "periodic mouths."

The *Ceratites* are distinguished by having the lobes of the sutures serrated, while the intervening "saddles" (or curves directed towards the aperture) are simple. They are found in the *trias* of Europe, Thibet, and South America; and again very rarely in the cretaceous strata of France and Syria,—a circumstance quite anomalous in the history of the geological distribution of life. Many Ammonites, perhaps all, are like Ceratites when young.

The species of Ammonite exceed 500; and their range is co-extensive with that of the secondary rocks. They are found throughout Europe, and at the Cape, in Kamtschatka, Thibet, and S. India. They are absent from a large area of the United States, but are found in the cretaceous strata of New Jersey, Missouri, and the West Indian Islands; also in Chile and Bogota. The sections into which, for the sake of convenience, this extremely natural group has been broken up, are very ill defined, and have no pretension to be considered sub-generic. The group (called *Cassiani*) characterizing the triassic period, is remarkable for many-lobed and elaborately-foliated sutures,—a circumstance more important, because it is the oldest group, and associated with *Ceratites* and the last-surviving *Goniatites* and *Orthocerata*. They abound in the "alpine limestone" of St Cassian, and Hallstatt in Austria. A second group (*Arietes*), having the back keeled, with a furrow on each side of the keel, as in the great Ammonites called *Bucklandi* and *Coneybearei*, mark the lias period; they are less plentiful in the oolites, and are represented in the greensands by the "Cristati," which are keeled, but not furrowed, and develop a "beak," or process, from the keel when adult. The "Arietes" pass by many intermediate forms into the "Falciferi" (*e.g.*, *A. serpentinus*), also characteristic of the upper lias, and these are represented by a few quoit-shaped species (*Disci*), with sharp backs, in the oolites.

Ammonites with serrated keels (*Amalthei*), exemplified by *A. spinatus* and *margaritatus*, abound in the middle and upper lias, and again in the oolites (*e.g.*, *A. cordatus* and *excavatus*). They are succeeded by the "Rothomagenses" in the chalk,—thick Ammonites with a line of tubercles in the place of the keel.

Ammonites with channelled backs (*Colliciati*) are represented in the lias (*A. anguliferus*), inferior oolites (*A. Parkinsoni*), and middle oolite (*A. anceps*), and in the cretaceous strata by numerous species (*e.g.*, *A. serratus*, *lautus*, and *falcatus*), remarkable for their elegance.

Of the species with backs more or less squared, *armatus* and *capricornus* occur in the lias, *athleta* and *perarmatus* in the Oxfordian. But the oolitic forms which have the back square, and ornamented with two rows of spines when young, like *Goweri*, *Duncani* (fig. 21, 2), and *Jason*, become rounded and unarmed in their old age.

Round-backed Ammonites abound in the lias and oolites. The snake-like *Annulatus*, the spine-bearing *coronatus*, and *fimbriatus* with its ornamental fringes, have been regarded as types of small groups. A more important division (*ligata*) is distinguished by nearly smooth whirls, constrictions recurring at regular intervals. These are seen in *A. tatricus*, and others related to *Heterophyllus*; in many neocomian Ammonites, and in *A. planulatus* of the lower chalk.

These constrictions, often accompanied by a prominent rib, undoubtedly indicate periods of rest, when the Ammonite ceased for awhile to grow. They may be traced in species belonging to other groups, as well, *e.g.*, in *biplex* and *triplicatus*, as in the *ligati*; but most frequently all indications are obliterated by subsequent growth. It has been a question whether the lateral processes of *Ammonites Duncani* (fig. 21, 2), are formed and removed periodically, or whether they are peculiar to the adults, and mark the close of their outward growth. The first conclusion is more probable from analogy; and they are commonly found with small and apparently young shells, but not (any more than the lateral spines of the living Argonaut) in those of adult size and condition.

It was remarked by the elder Sowerby that Ammonites were most beautiful when of middle growth, the ornamental characters being less developed in the young, and lost in the adult. The ribs and spines, and even the keel or furrow of the back disappear, in many instances, from the body-whirl of the full-grown shell.

Varieties of form, such as marked the palæozoic *Nautilidæ*, are met with in the *Ammonitidæ*, chiefly towards the close of their reign. The Baculite (fig. 21, 4), with its straight shell, is characteristic of the upper chalk; and the *Turrilite*, which is spiral, and usually a left-handed spiral, abounds in the lowest beds of the same formation. In *Hamites* the shell is straight, returning upon itself after a certain space, and forming a simple or complex hook. In *Ptychoceras* these limbs of the hook-like shell are in close contact. The *Toxoceras* is curved like a bow; in *Crioceras* the discoidal whirls are separate; and in *Scaphites* (including *Ancyloceras*) the shell, at first compact like an Ammonite, or open-whirled like *Crioceras*, lengthens out finally, and returns upon itself like the crozier of the *Hamite*. *Helicoceras*, again, connects the last with the *Turrilite* by its elevated spire terminating in a prolonged crozier.

Of these forms, *Ancyloceras* alone is found in the oolites; all the rest are cretaceous; and most abound in the alpine districts of the south of France.

Order 2.—DIBRANCHIATA.
(*Cuttle-fishes.*)

Of the two great divisions of cephalopodous Mollusca, that which is represented at the present day by the pearly *Nautilus* was developed in the greatest profusion and variety in the palæozoic and secondary periods; whilst the more active and intelligent cuttle-fishes and squids have not been (certainly) found in rocks older than the lias, and scarcely above 100 are found in the whole secondary and tertiary series, while twice as many have been obtained in existing seas.

The *Sepiadæ* are represented in the middle and upper oolites by the genus *Coccoteuthis* (fig. 22, 6), whose strong and granulated bone is furnished with broader lateral expansions than the recent cuttle-fishes. In the older ter-

tiaries of London and Paris, many species of *Sepia* appear to have existed, but only the solid *mucro* (fig. 22, 5) of the shell is usually preserved. In the miocene tertiary of Malta, a diminutive cuttle-bone is not rare; and at Turin a remarkable form (*Spirulirostra*, fig. 22, 7) has been discovered, in which the apex is provided with a chambered and siphonated cavity like the shell of the *Spirula*. Two other genera, *Beloptera* (fig 22, 8) and *Belemnoris*, very imperfectly known by rare and fragmentary examples, occur in the eocene tertiary.

Remains of the *Calamaries* (*Loligidæ*) are often found in the fine-grained and laminated argillaceous limestones of the lias and Oxford clays, as at Lyme Regis, and Böll of Solenhofen. Some of these are slender, like the pens of the recent *Omonastrephes*, and furnished with a small conical appendix, as in that genus; whilst others are broad, and pointed at each end (*Beloteuthis*). The most common form has the shaft wide and longer than the wings, and is truncated posteriorly. It has a nacreous lining, and is usually accompanied by a large and well-preserved ink-bag (fig. 22, 4). These were called *Belemnosepia* by Agassiz and Buckland, who supposed them to belong to the same animal with the Belemnite. They have also been called *Loligo-sepiæ* and *Loliginites;* but the name *Geoteuthis*, given by Count Münster, appears least objectionable. One species (*Mastigophorus latificum*) is of frequent occurrence in the Oxford clay near Chippenham, which retains not only the horny (*chitinous*) pen and ink-bag, but also the muscular slieve, the rhombic terminal fins, and at least the bases of the arms, with the minute hooks, and traces of the mandibles. Horny claws, like those of the uncinated Calamary (*Onychoteuthis*), have been observed arranged in double series in the lias of Watchett, and they sometimes occur in great numbers in the coprolitic remains of the *Enaliosauri*. The most remarkable examples of this kind are preserved in the lithographic limestones of Solenhofen, and show that the extinct Calamary had ten nearly equal arms, the tentacles, in their retracted condition, being undistinguishable from the rest—each furnished with 20 to 30 pairs of formidable hooks. What further evidence was

needed respecting the nature of this creature has been supplied by the Chippenham fossils, which in all probability are identical in genus, if not in species, with the *Acanthoteuthis*, described by Münster. One of these extraordinary fossils—the mummy of a cuttle-fish more ancient than the chalk formation and the upper oolites—is represented in fig. 22, 2, reduced to one-sixth from the original in the British Museum. Nine of the arms are preserved, the sclerotic plates of the eyes, the bases of the large lateral fins, the small ink-bag, and the conical shell. This shell, which is chambered internally, like the *phragmocone* of the Belemnite (fig. 22, 1), has an outer sheath of fibrous structure, one-fourth of an inch thick at the apex, and furnished with two converging ridges on its dorsal side; the external surface, however, is horny (or chitinous), like the pen of the Calamary. These chambered shells occur in great numbers, and are so like the phragmocones of the associated Belemnites, both in structure and proportions, that it is difficult to avoid believing they are in some way related; but hitherto they have only been noticed in the laminated Oxford clay of Wilts and the equivalent lithographic shales of Solenhofen.

The Belemnite, on the other hand, is found in all the oolitic and cretaceous strata, from the lowest lias to the upper chalk. In its ordinary imperfect state, it is a cylinder pointed at one end, and truncated or excavated by a funnel-shaped cavity (*alveolus*) at the other, and has a radiating fibrous structure, with less distinct concentric laminæ of growth. But even this "guard," which corresponds simply to the *mucro* of the cuttle-bone, exhibits such remarkable modifications of form, that nearly 100 species have been founded upon no higher evidence. In some Belemnites of half an inch diameter, the guard is scarcely an inch longer than the phragmocone, whilst in others it attains a length of ten inches, and is tubular, as in *B. acuarius*. Some are fusiform, others laterally compressed; some have a longitudinal groove extending from the apex along the upper or under side, and in others the apex is furrowed laterally as well. The Belemnites of the chalk have been called *Belemnitellæ* (D'Orb.), because they have a slit in the ventral side of the alveolar border of the guard; their external surface also exhibits more distinct traces of vascular impressions.

Specimens of Belemnite have been discovered in which the guard had been broken during the lifetime of the animal; but the broken portions being held together by the investing organized integuments, had been re-united by the deposition of new layers of the fibrous structure peculiar to the guard. Several examples of Belemnites, with the apex injured and healed during life, are preserved in the British Museum. In all perfect Belemnites, the *alveolus* is occupied by a *phragmocone*, with tender nacreous walls and septa, and terminating in a minute globular apex, and perforated by a ventral *siphuncle* (fig. 22, 1). The last chamber is rarely preserved, and appears to have thinned off into a mere horny sheath, with sometimes two pearly bands like knife-blades on the dorsal side. It must have been sufficiently capacious to contain all the viscera. The ink-bag has been very rarely found, and is even smaller than in the last genus, as if in relation to the more greatly developed shell.

The *Conoteuthis* (fig. 22, 3) of the Gault has an oblique phragmacone, with a very thin shell, and seems to have been attached to a slender style, like the funnel-shaped appendix of the gladius in the recent sagittated Calamary.

Mr Dana has described, under the name *Helicerus Fugiensis*, a belemnitoid fossil from the "slate" rock of Cape Horn. It is half an inch in diameter, has a thick fibrous guard, and the slender phragmacone terminates in a fusiform spiral nucleus.[1]

Subjoined is a table of the extinct genera of the molluscous province :—

---

[1] For the drawings and most of the facts relating to invertebrate fossils, the writer is indebted to his experienced colleague in charge of that department of the British Museum, Mr S. P. Woodward, F.G.S.

Vertebrata.

BRACHIOPODA.—Trigonosemus, Lyra, Magas, Rhynchora, Zellania, Stringocephalus, Meganteris; Spirifera, Cyrtia, Suessia, Athyris, Merista, Retzia, Uncites; Camarophoria, Porambonites, Pentamerus, Atrypa, Anoplotheca; Orthis, Orthisina, Strophomena, Koninckia, Davidsonia, Calceola; Producta, Chonetes, Aulosteges, Strophalosia; Trematis, Siphonotreta, Obolus.

CONCHIFERA.—Gryphæa, Exogyra, Limanomia, Carolia, Placunopsis, Neithea, Eligmus; Pteroperna, Aucella, Ambonychia, Cardiola, Eurydesma, Pterinea, Monotis, Posidonomya, Aviculopecten, Gervillia, Streblopteria, Pulvinites, Inoceramus, Trichites; Megalina, Orthonotus, Modiolopsis, Hoplomytilus; Macrodon, Isoarca, Bakewellia, Nuculina, Nucinella, Cucullella, Ctenodonta; Myophoria, Axinus, Lyrodesma; Diceras, Monopleura, Requienia; Hippurites, Radiolites, Caprinella, Caprina, Caprotina; Lithocardium, Conocardium, Corbicella, Sphæra, Unicardium, Tancredia, Volupia; Pleurophorus, Myoconcha, Anthracosia, Megalodon, Pachydomus, Pachyrisma, Cleobis, Mæonia, Opis, Cardinia, Hippopodium, Megaloma; Grateloupia, Sowerbya, Quenstedtia, Goniophora, Redonia; Cercomya, Myacites, Goniomya, Grammysia, Ceromya, Cardiomorpha, Edmondia, Ribeiria.

GASTEROPODA.—Bellerophon, Porcellia, Cyrtolites, Ecculiomphalus; Rimella, Hippocrena, Alaria, Spinigera, Amberlya; Leiostomus, Strepsidura, Purpurina, Columbellina, Borsonia, Conorbis; Euspira, Naticopsis, Globulus, Deshayesia, Loxonema, Macrochilus; Diastoma, Nerinæa, Brachytrema, Ceritella, Vicarya, Scoliostoma, Proto, Holopella, Catantostoma, Naticella; Platyceras, Metoptoma, Hypodema, Deslonchampsia; Euomphalus, Ophileta, Phanerotinus, Serpularia, Discohelix, Platystoma, Crossostoma, Pleurotomaria, Murchisonia, Polytremaria, Cirrus, Trochotoma, Platyschisma, Scalites, Rhaphistoma, Holopea, Maclurea; Neritoma, Velates, Pileolus; Helminthochiton; Lychnus, Dendropupa, Ferussina; Cylindrites, Acteonina, Acteonella, Cinulia, Globiconcha, Varigera, Tylostoma, Pterodonta, Volvaria, Chilostoma; Vaginella, Theca, Pterotheca, Canularia.

CEPHALOPODA.—Aturia, Discites, Nautiloceras, Trigonoceras, Temnochilus, Lituites, Trocholites, Trochoceras, Clymenia; Orthoceras, Camaroceras, Huronia, Actinoceras, Discosorus, Gonioceras, Tretoceras, Apioceras, Gomphoceras, Phragmoceras, Cyrtoceras, Gyroceras, Ascoceras; Goniatites, Bactrites, Ceratites, Ammonites, Crioceras, Toxiceras, Ancyloceras, Scaphites, Helicoceras, Turrilites, Hamites, Ptychoceras, Baculites; Teudopsis, Beloteuthis, Geoteuthis, Leptoteuthis, Belemnites, Acanthoteuthis, Helicerus, Conoteuthis, Coccoteuthis, Belosepia, Spirulirostra, Beloptera, Belemnosis.

PROVINCE IV.—VERTEBRATA.

There is an enormous series of subaqueous sediment, originally composed of mud, sand, or pebbles, the successive bottoms of a former sea, derived from pre-existing rocks, which has not undergone any change from heat, and in which no trace of organic life has yet been detected. These non-fossiliferous, non-crystalline, sedimentary beds form, in all countries where they have yet been examined, the base-rocks on which the Cambrian or oldest Silurian strata rest.

Whether they be significative of ocean abysses never reached by the remains of coeval living beings, or whether they truly indicate the period antecedent to the beginning of life on this planet, are questions of the deepest significance, and demanding much farther observation before they can be authoritatively answered.

It has been shown that every type of invertebrate animal is represented in the superimposed stratified deposits called Cambrian and lower Silurian.

Vertebrata.

An important work,[1] embodying the labours of the accomplished naturalist and acute observer, Dr Christian H. Pander, has recently been published by the Russian government, descriptive of the fossil fishes of the Silurian formations of that empire. Of some hundred fossils described and beautifully figured in this work, and referred to different genera and species of fishes, from lower Silurian rocks, the writer, after the closest comparison and consideration of the evidence, is disposed to regard only those referred by Pander to the genera *Ctenognathus*, *Cordylodus*, and *Gnathodus*, as having any probable claims to vertebrate rank; and to this admission must be appended the remark, that the parts referred to jaws and teeth may be but remains of the dentated claws of *Crustacea*. With regard to the fossils called "Conodonts," on which the main part of M. Pander's evidence of lower Silurian fishes rests, the following remarks, penned after microscopic examination of specimens kindly submitted to the writer by Sir Roderick Murchison, are applicable to them.

Minute, glistening, slender, conical bodies, hollow at the base, pointed at the end, more or less bent, with sharp opposite margins, might well be lingual teeth of Gastropods, acetabular hooklets of Cephalopods, or teeth of cartilaginous fishes. Against the latter determination is the minute size of the "Conodont" bodies. Their basal cavity doubtless contained a formative pulp, but the proof that the product of such pulp was "dentine" is wanting: the observed structure of the hooklet presents concentric conical lamellæ of a dense structureless substance, containing minute nuclei or cells.

In some specimens the base is abruptly produced and divided from the body of the hooklet by a constriction,—a form unknown in the teeth of any fishes, but presented by certain lingual teeth of Gastropods,—*e.g.*, the lateral teeth of *Sparella*. In other Conodonts the elongated base is denticulate or serrate, as in the lateral teeth of *Buccinum* and *Chrysodomus*. It is improbable, however, that they belong to any conchiferous toothed Mollusk, the shells of such being wanting in the deposit where the Conodonts are most abundant.

The more minute hooklets have a yellowish, transparent, horny appearance; the larger, perhaps older ones, present a harder whitish appearance. Their analysis by Pander yielded "carbonate of lime," carbonic acid being evolved by application of dilute nitric acid, and oxalic acid producing an obvious precipitate. Some English analysts have believed that the Conodonts yielded a trace of phosphate of lime.

The detached condition of the hooklets, and the integrity of the thin border of the basal pulp-cavity, indicate that they have not been broken away from any of those kinds of attachment to a bone which the minute villiform teeth of osseous fishes would show signs of. The Conodonts have been supported upon a soft substance, such as the skin of a Mollusk or worm, the mucous membrane of a mouth, or throat, or the covering of a proboscis; but to select the teeth of cyclostomous or plagiostomous fishes as the exclusive illustration of the above condition, is to take a partial and limited view of the subject.

In comparing the Conodonts with the teeth of fishes, they present, as Dr Pander recognises, most resemblance with the conical, pointed, horny teeth of Myxinoids and Lampreys in that class: and the absence of any other hard part in the strata containing the Conodonts tallies with the condition of the cyclostomatous skeleton; but not more than it does with the like soft condition of annelidous worms and naked Mollusks. But the teeth of all known Cyclostomes are

[1] *Monographie der Fossilen Fische* (*Untersilurische Fische, Conodonten*, &c.), 4to, Petersburgh, 1856.

Vertebrata.

Plagiostomes.

much less slender and are less varied in form than in the Conodonts. Certain lingual plates of Myxinoids are serrate, but not with a main denticle of much greater length,—such as shown in the form of the Conodont called *Machairodus* by Pander. Most cyclostomous teeth are simple, thick cones, with a subcircular base; and every known tooth of a cyclostomous fish is much larger than any of the forms of *Conodon*, which rarely equal half a line in length. This minuteness of size, with the peculiarities of form, supports a reference of the Conodonts rather to some soft invertebrate genus. Certain parts of small Crustacea,—*e.g.*, the pygidium or tail of some minute *Entomostraca*,—resemble in shape the more simple Conodonts; but when we perceive that these bodies occur in thousands, detached, with entire bases, and that any part of the carapace, or shell of an Entomostracan or other Crustacean, has been rarely detected in the lower Silurian Conodont beds, it is highly improbable that they can have belonged to an organism protected by a substance as susceptible of preservation as their own substance. Much more likely is it that the body to which the minute hooklets were attached was as soluble and perishable as the soft pulp upon which the Conodont was sheathed. The writer finds no form of spine, denticle, or hooklet in any Echinoderm, and especially in any soft-bodied one, to match the Conodonts; and concludes that they have most analogy with the spines, or hooklets, or denticles of naked Mollusks or Annelides. The formal publication of these minute ambiguous bodies of the oldest fossiliferous rocks, as evidences of fishes, is much to be deprecated.

Order I.—PLAGIOSTOMI.

(*Sharks, Rays*)

Char.—Endo-skeleton cartilaginous or partially ossified; exo-skeleton placoid; gills fixed with five or more gill-apertures; no swim-bladder; scapular arch detached from the head; ventrals abdominal; intestine with spiral valve.[1]

The earliest good evidence which has been obtained of a vertebrate animal in the earth's crust is a spine, of the nature of the dorsal spine of the dog-fish (*Acanthias*), and of the dorsal spines of the extinct *Acanthodii*. It occurs in the most recent deposits of the Silurian period, in the formation called "Ludlow rock." Its discovery is due to Murchison;[2] its determination to Agassiz, who assigns it to a genus of plagiostomous cartilaginous fishes called *Onchus*.

The *Onchus* spines from the Ludlow bone-beds are compressed, slightly curved, less than two inches in length, with no trace at their base of the joint characteristic of the dorsal spines of the "sheat-fishes" (Ganoids of the family *Siluridæ*), or "file-fishes" (*Balistidæ*). The sides of the spine are finely grooved lengthwise, with rounded ribs between the grooves. They are referred to two species—*Onchus Murchisoni*, and *O. semistriatus*. Sir P. Egerton has lately figured another species from the argillaceous beds near Ludlow, which is more curved, and is armed along the posterior edge; the longitudinal ribs are fine and numerous, but are constricted at intervals, as in the genus *Ctenacanthus*, and become subtuberculate at the base. He deems them significant of a distinct genus of shark-like fishes.[3]

With the dorsal spines of *Onchus* are found petrified portions of skin, tubercular and prickly, like the shagreen of shark's skin, and referred to a genus called *Sphagodus*; also coprolitic bodies of phosphate and carbonate of lime, including recognisable parts of the small Mollusks and Crinoids which inhabited the sea-bottom in company with the Onchus-fish. No vertebræ, or other parts of the endo-skeleton of a fish, have been discovered, unless the fragments of a calcified bar, with tooth-like processes, called *Plectrodus*, be truly jaws with teeth. They resemble, however, parts of the pincer-claws of Crustaceans, as well as of the jaws and teeth of fishes, and do not indicate that class so satisfactorily as the *Onchus* spines and *Sphagodus* shagreen. Yet the denticles are confluent with an outer ridge of the bone, according to the "pleurodont" type, and consist of separated large teeth, with minute serial teeth in the interspaces; and the large teeth are grooved longitudinally.[4]

If the Plectrodonts be jaws with anchylosed teeth, they belong to an order distinct from the *Plagiostomi*. If they should belong to any of the fishes indicated by the dorsal spines and shagreen skin, a combination of characters would be exemplified not known in other formations or in any existing fishes.

No detached teeth unequivocally referable to a plagiostomous genus, nor any true ganoid scale of a fish, have yet been found in the formations that have revealed these earliest known evidences of vertebrate animals. What, then, it may be asked, were the conditions under which so immense an extent, as well as amount, of sediment was deposited,—including chambered Cephalopods, Gastropods, Lamellibranchs, Brachiopods, various and large trilobitic Crustaceans, with Crinoids, Polypes, and Protozoa,—that precluded the preservation of the fossilizable parts of fishes, if that class of vertebrate animals had existed in numbers, and under the variety of forms, comparable to those that people the ocean at the present day? Bonitos now pursue flying-fishes through the upper regions of an ocean as deep as any known part of the Silurian seas of which the deposits afford an idea of greatest depth. If fishes of cognate habits with the present deep-sea fishes, under whatever difference of form such Silurian fishes may have been manifested, had really existed, we might reasonably expect to find the remains of some of the countless generations that succeeded each other during that vast and indefinite period, sufficing for the gradual deposition of sedimentary beds of thousands of feet in depth or vertical thickness.

The evidences of plagiostomous fishes afforded by fossil spines will be here pursued. In most of the existing cartilaginous fishes of this order the defensive spine which stands erect in front of the dorsal fin is smooth; such is the case in the dog-fishes (*Spinacidæ*) in which each dorsal fin is fronted with a spine. In the Port-Jackson sharks (*Cestraciontidæ*) the spine in front of each dorsal is bony, and is armed along its hinder or concave border with bent spines. The fin is connected with this border, and its movements are regulated by the elevation or depression of the spine during the peculiar rotatory action of the body of the shark. This action of the spine in raising and depressing the fin resembles, Dr Buckland has remarked, that of the moveable or jointed mast, raising and lowering backwards the sail of a barge. But their more obvious use, in the small Plagiostomes possessing such spines, is as defensive weapons against the larger and stronger voracious fishes.

Certain bony fishes are similarly armed,—*e.g.*, sticklebacks (*Gasterostei*), sheat-fishes (*Siluridæ*), trigger-fishes (*Balistes*), and some species of snipe-fishes (*Fistularidæ*). In the latter family the *Centriscus humerosus* (fig. 23) shows a dorsal spine, denticulated behind, as in the Cestracionts, but the base of the spine in bony fishes is peculiarly modified for

[1] For an explanation of the technical terms in these characters, see the article ICHTHYOLOGY, especially of the scales, vol. xii., p. 216.

[2] *Silurian System*, ch xlv., p. 606.

[3] In a formation in Indiana, United States of America, referred by Messrs Norwood and Dale Owen to the Silurian formation, a badly-preserved fossil, considered as an Ichthyolite, and referred to a genus allied to *Pterichthys*, has been discovered, and called *Macropetalichthys raphidolabis*. (Silliman's *Journal*, 1846, p. 367.)

[4] Egerton, *Proc. Geol Soc.*, March 1857, p. 288, pl. x., figs. 2–4.

Vertebrata.

articulation with another bone. In the Plagiostomes the base of the spine is hollow, becomes thin and smooth when the body of the spine is sculptured, and is in the recent fish implanted in the flesh.

The following genera of plagiostomous fishes have been

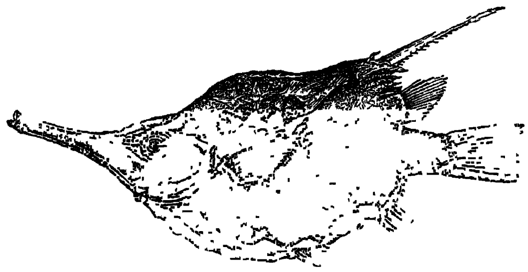

Fig. 23.

Centriscus humerosus.

founded on the fossil spines, or "ichthyodorulites," which have been discovered in the "Devonian," or "Old Red Sandstone series." *Onchus* (represented by *O. semistriatus*, *O. heterogyrus*), *Dimeracanthus*, *Haplacanthus*, *Narcodes*, *Naulas*, *Byssacanthus*, *Cosmacanthus*, *Homacanthus* (fig. 24), *Ctenacanthus*, *Ptyacanthus*, *Climatius*, *Parexus*, *Odontacanthus*, and *Pleuracanthus*.

The genus *Homacanthus* is founded on small compressed spines, with fine recurved teeth on the back edge, and longitudinal striæ on the sides. Specimens of *Homacanthus arcuatus* (fig. 24) have been found in Devonian formations near St Petersburg.

Fig. 24. *Homacanthus arcuatus.* (Devonian, Russia.)

The carboniferous series of formations includes the mountain limestone, millstone grit, and the coal measures (see fig. 1). In this series the genus *Onchus* is still represented by the *O. sulcatus*, *O. rectus*, and *O. subulatus;* and the genus *Homacanthus*, by *H. macrodus* and *H. microdus*, from the carboniferous limestone of Armagh. *Ptyacanthus*, *Ctenacanthus*, and *Pleuracanthus* are also forms common to the Devonian and carboniferous periods. The spine of the latter genus is denticulated along both margins, a structure which is presented, in existing Plagiostomes, only by species of the ray family: *Pleuracanthus*, therefore, as Agassiz concludes, may offer the earliest example of the flat form of cartilaginous fish, which is represented by the sting-rays (*Trygon*, *Myliobates*) in the present seas. The ichthyodorulite (*ichthys*, a fish; *dora*, a spear; *lithos*, a stone) here selected to illustrate this fossil, is a portion of the spine of the *Pleuracanthus levissimus* (fig. 25), from the carboniferous beds near Dudley. The other plagiostomous genera based upon fossil spines from the coal formations are,—*Oracanthus*, *Gyracanthus*, *Nemacanthus*, *Cosmacanthus*, *Leptacanthus*, *Homacanthus*, *Trystichius*, *Asteropterychius*, *Physonemus*, *Sphenacanthus*, *Platyacanthus*, *Dipriacanthus*, *Erismacanthus*, *Orthacanthus*, *Cladacanthus*, *Lepracanthus*.

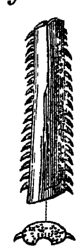

Fig. 25. *Pleuracanthus levissimus.* (Coal, Dudley).

Immediately above the coal-measures lie a variable series of sands and clays of different colours, including the coal plants: above this, a marl-slate in thin layers, containing scanty evidences of fishes; but these are more abundant and instructive in the superincumbent magnesian limestone, in which formation near Belfast ichthyodorulites of the genus *Gyropristis* (Ag.), have been found. Above this are the penean red sandstones, in which, at Westoe, have been found fossil spines closely allied to, if not identical with, the *Gyracanthus formosus* (Ag.) The foregoing formations constitute the uppermost of the palæozoic series called "Permian," from the Russian province in which these strata are most extensively developed. Their relative position is known by the term "magnesian limestone" in the "Table of Strata," fig. 1.

Vertebrata.

The superimposed strata, marked "new red sandstone," includes also a varied series of red and white sands, marls, and conglomerates, forming collectively the system called "triassic." The ichthyodorulites of this system are referable to the genera *Nemacanthus*, *Leiacanthus*, and *Hybodus*. In the "lias," which is the oldest or lowest of the great "oolitic" system, the dorsal spines of the genus *Hybodus* (fig. 26), are the largest and most abundant; this genus, however, is represented by detached teeth in the keuper and muschelkalk members of the "trias." The lias formations give evidence that the dorsal spines and fins of *Hybodus* were two in number; and the genus is shown, both by the structure of the spine and the form of the teeth, to have had its nearest affinities with the *Cestracion* amongst existing Plagiostomes. *Hybodus* continued to be represented by successive and varying specific forms up to, and including, the cretaceous period. *Hybodus* is therefore a genus of cartilaginous fishes eminently characteristic of the secondary or mezozoic period in palæontology, and ranges through every formation of that period. The specimen selected for the illustration of the dorsal spine of *Hybodus* is that of the *H. subcarinatus*, from the Wealden of Tilgate Forest.

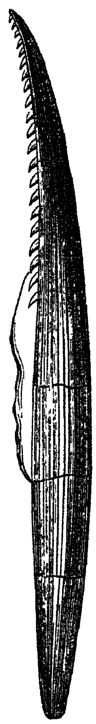

Fig. 26. *Hybodus subcarinatus.* (Wealden.)

Large fossil spines, longitudinally grooved, have been found associated with the teeth of the extinct cestraciont genus of the chalk called *Ptychodus*.

In the tertiary formations, the fossil spines present for the most part the generic characters of those of existing Plagiostomes,—*e.g.*, *Spinax*, *Trigon*, and *Myliobates;* but one form, found in the eocene beds near Paris, is the type of the extinct genus *Aulacanthus* of Agassiz.

The teeth of the plagiostomous fishes,—viz., sharks (*Squalidæ*), rays (*Raiidæ*), and Cestracionts, are described in the article ODONTOLOGY (vol. xvi., pp. 422–424). From the account and figures there given, it will be seen that the teeth are very numerous, and that, being attached only by ligament to the membrane of the mouth, they must soon fall off in the decomposition of the dead fish, become scattered abroad by the movements of the body through the action of the waters, and sink into the sediment.

FAMILY I.—CESTRACIONTIDÆ.

(Port-Jackson Shark.)

The existing genus which has thrown most light upon the fossil teeth which have thus become imbedded in the oceanic deposits of the palæozoic and mezozoic periods, is the *Cestracion*, now restricted to the Australian and Chinese seas, where it is represented by two or three species, and suggests the idea of a form verging towards extinction. It formerly flourished under a great number of varied generic or family modifications, represented by species, some of which attained dimensions far exceeding the largest known living Cestracions. The dentition of these fishes is adapted to the prehension and mastication of crustaceous and testaceous animals; they are of a harmless, timid character; and have the before-described denticulate dorsal spines given to them as defensive weapons. Figure

Vertebrata.

27 gives a side view of the upper and lower jaws of the "Port-Jackson shark," showing the oblique disposition of the large crushing teeth, which cover like a pavement the working borders of the mouth. Figure 28, p. 424, article ODONTOLOGY, gives a view of the crowns of the teeth of the upper jaw of the same species. From their mode of attachment, these teeth would become detached from the jaws of the dead fish, and dispersed in the way above described; and it is by such detached fossil teeth that we first get dental evidence of the Cestraciont family in former periods of the earth's history.

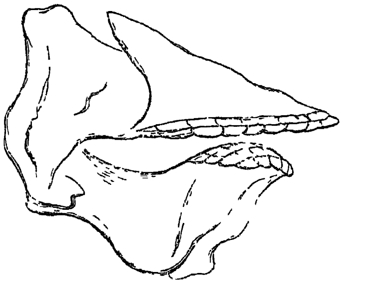

Fig. 27.
Cestracion Philippi (recent).

The teeth of the Hybodonts are conical, but broader and less sharp than those of true sharks. The enamel is strongly marked by longitudinal grooves and folds. One cone is larger than the rest, and called the "principal;" the others are secondary. In one genus (*Cladodus*, Ag.), the secondary cones go on enlarging as they recede from the "principal;" and teeth of this genus, referred by Eichwald to the *Hybodus longiconus*, have been discovered in the old red sandstone in the vicinity of Petersburg.

In the *Orodus*, the cones are more compressed, trenchant, and distinct from the body of the tooth than in *Hybodus*; but they present a principal and secondary cones. Fig. 28 is a tooth of the *Orodus cinctus* (Ag.), from the carboniferous beds near Bristol. The *O. porosus* and *O. compressus* are from deposits of similar age near Armagh.

Fig. 28.
Orodus cinctus (tooth).
(Carboniferous.)

If fig. 29 be compared with fig. 28, p. 424, vol. xvi., it would seem as if the several teeth of each oblique row in *Cestracion* had been welded into a single dental mass in *Cochliodus*, the proportions and direction of the rows being closely analogous. Whether in *Cochliodus* there were any small anterior prehensile teeth, is hypothetical; the large crushing dental plates must have been admirably adapted to crack and bruise the shells of Molluscs and Crustaceans. The *Cochliodus contortus* (Ag.) (fig. 29) has been found in the carboniferous formations near Bristol and Armagh, aud the genus is peculiar to that geological period.

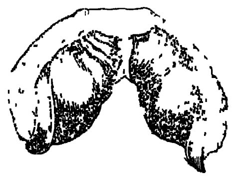

Fig. 29.
Cochliodus contortus, Ag.
(Carboniferous.)

Teeth referable to the genus *Hybodus* occur in all the secondary rocks from the trias to the chalk inclusive.

A form of tooth which more closely resembles the crushing-teeth of Cestracion, is that on which the genus *Acrodus* is founded, and which also ranges from triassic strata to the upper chalk of Maestricht. The species here selected (fig. 30) is the *Acrodus nobilis*, from the lias of Lyme Regis. The upper figure shows the grinding surface, which, from its finely and transversely striated character and dark colour, has suggested to the quarrymen the name of "fossil leeches." The older fossilists regarded these teeth as petrified Vermes; but the structure, as shown by the microscope, is closely similar to that of the teeth of Cestracion.[1] Portions of the jaw of the *Acrodus* have been discovered which show that these teeth were arranged, as in *Cestracion*, in oblique rows, with at least seven teeth in each row. *Acrodus lateralis* is a muschelkalk fossil, *A. hirudo* a Wealden, and *A. transversus* a cretaceous fossil. No tooth referable to the genus has been found in any tertiary stratum.

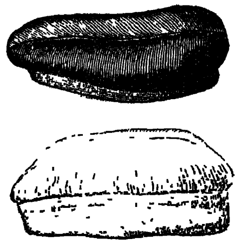

Fig. 30.
Acrodus nobilis (tooth).
(Lias.)

Vertebrata.

The genus *Ptychodus* is founded on teeth usually of large size, and of a more or less square form (fig. 31). The crown is deeper than the root, which is obtuse and truncate. The enamelled summit of the crown is granulate at the margin, and raised in the middle into an obtuse eminence, disposed in large transverse, parallel, sometimes wavy and rather sharp ridges. With teeth of this form are sometimes found others of smaller size, with more convex rounded crowns, doubtless forming the extremes of the multiserial pavement which, as in modern sharks and rays, covered the broad jaws of the Ptychodonts. Large dorsal spines have been found so associated with the above-described teeth as to indicate the affinity of the *Ptychodus* to the Cestraciont family of sharks. All the specimens and species referable to this genus have been found in the cretaceous strata.

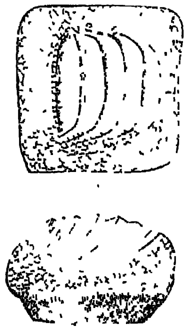

Fig. 31.
Ptychodus latissimus.
(Chalk.)

FAMILY II.—SQUALIDÆ
(*Sharks.*)

The well-marked, saw-shaped tooth (fig. 32), so closely resembles the lower jaw-teeth of the sharks, called "grisets" by the French (*Notidanus*, Cuv.), as to be referred to that genus by Agassiz. Such teeth nevertheless occur in strata of oolitic age (*Notidanus Munsteri*, Ag., fig. 32). Other species,—*e. g.*, *N. pectinatus*,—are found in the chalk of Kent; and *N. serratissimus*, in the eocene clay at Sheppy.

The tooth (fig. 33) on which Agassiz has founded the genus *Corax* indicates, by its close resemblance to those of *Carcharias*, its relationship with the true sharks (*Squalidæ*). Most of the species of *Corax*, including *C. falcatus*, are cretaceous; a few are tertiary: all are extinct.

Notidanus Munsteri.
(Upper Oolite.)

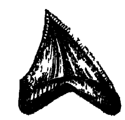

Fig. 33.
Corax falcatus.
(Chalk.)

Fig. 34.
Galeocerdo aduncus.
(Miocene.)

Another form of shark's tooth, deeply notched at one margin, and with the rest of the border finely denticulate, resembles more that of the "Topes" or gray sharks (*Galeus*, Cuv.), and is referred by Agassiz to the genus *Galeocerdo*. The species are found in both the cretaceous and tertiary formations; *Galeocerdo aduncus* (fig. 34) is from the miocene of Europe and America. In the same tertiary series are found the teeth of the *Hemipristis serra*, Ag. (fig. 35).

Odontaspis (Ag.), presents a form of tooth most like that in the blue sharks (*Lamna*) of the present seas. Species of *Odontaspis* occur in the cretaceous and tertiary beds. The *O. Hopei* (fig. 36) is from the London clay of Sheppy. It indicates a destructive and formidable species of shark.

[1] See Owen' *Odontography* vol. i. p. 54, pls. 14 and 15.

With these fossil teeth of sharks are found, though sparingly, in both the cretaceous and tertiary beds, petrified bodies of vertebræ, showing by their extreme shortness in comparison with their breadth, by their bi-concavity,

(London clay, Sheppy.)

and the fissures on the external surface (as shown on the upper figure of cut 37), that they belonged to a shark closely allied to the Porbeagle, (*Lamna*, Cuv.)

Family III.—Raiidæ.

(*Rays.*)

Fossil evidences of this peculiar family of cartilaginous fishes have been discovered in oolitic, cretaceous, and tertiary formations, and consist of defensive spines, dermal tubercles, and teeth, but chiefly the latter. The most peculiar and distinctive modifications of the dental system, presented by the eagle-rays (*Myliobatidæ*) are unequivocally shown by fossils of the tertiary formations, and have not been found in earlier strata.

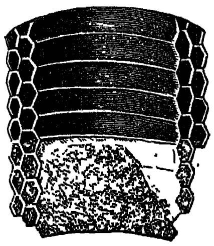

Fig. 38.
Myliobates toliapicus.
(Eocene, Sheppy.)

The form, structure, and arrangement of the dental plates of the existing *Myliobates* are described and illustrated in the article Odontology, p. 423, figs. 26 and 27. To this genus, as now restricted, certain fossils from the London clay of Sheppy (*Myliobates toliapicus*, Ag., fig. 38) belong.

In *Zygobates* (fig. 39), the middle series of teeth is less broad; and a still narrower series is interposed between it and the small lateral teeth. Existing rays showing this modification are found in Brazilian seas; fossil teeth of this genus, *e.g.*, *Zygobates Woodwardi*, Ag. (fig. 39), occur in the tertiary crag (probably miocene) of Norfolk, and in the miocene mollasse of Switzerland.

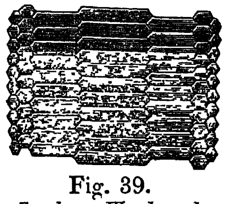

Fig. 39.
Zygobates Woodwardi.
(Miocene.)

When the teeth form broad transverse undivided plates, as in fig. 40, they characterize the genus *Ætobates.* Fossils of this genus occur in the English eocenes and the Swiss mollasse.

In the "crag" of Norfolk and Suffolk, and in marine pliocene beds, fossils have been found which closely resemble the osseous and spinigerous plates that beset the skin of the ray, thence called "thornback" (fig. 41), and which indicate the existence of a species allied to the *Raia clavata.*

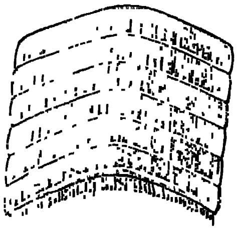

Fig. 40.
Ætobates subarcuatus.
(Eocene, Bracklesham.)

Thus we obtain evidence of fishes of the plagiostomous order in the marine deposits of every formation from the upper Silurian beds to the present period. But none of the palæozoic fossils are referable to any existing genus. A few only of the mezozoic Plagiostomes, and those chiefly from the chalk are so determinable. Most of the secondary Plagiostomes belong or are allied to a family (*Cestraciontidæ*), now nearly extinct; the evidence of the generic forms of Plagiostomes characteristic of the present time become common only in the tertiary periods. No fossil species is the same with any existing one.

Fig. 41.
Raia clavata
(Dermal spines)

Order II.—HOLOCEPHALI.

(*Chimæroid Fishes.*)

Char.—Jaws bony, traversed and encased by dental plates; endo-skeleton cartilaginous; exo-skeleton as placoid granules; most of the fins with a strong spine for the first ray; ventrals abdominal; gills laminated, attached by their margins; a single external gill aperture.

To judge from the paucity of existing representatives of this order of cartilaginous fishes, it would seem, like the Cestracionts, to be verging towards extinction. One genus (*Chimæra*, Linn.) is founded on a single known species of the northern seas called "king of the herrings" (*Chimæra monstrosa*); another genus (*Callorhynchus* of Gronovius) is represented by two known species in the Australian and Chinese seas. The only parts of chimæroid fishes likely to be fossilized are the jaws and spines. The bony and dental substances are so combined in the more or less beak-shaped jaws, that they characterize the order, and are never found separate. It is chiefly on such fossil mandibles, and portions of them, that the evidence of the *Holocephali* in former geological periods rests. These singular fishes ranged, under different generic and specific modifications, from the bottom of the oolitic series to the present period.

Genus Ischiodon, Egerton.—Of this genus, *I. Johnsoni* is from the lias of Dorsetshire; *I. Egertoni* from the Kimmeridge of Shotover; and *I. Townshendi*, a magnificent species, from the Portland stone. Two species (*I. Agassizii* and *I. brevirostris*) are from the cretaceous beds; at which period the genus appears to have perished.

Genus Ganodus, Egerton (including *Ganodus* and *Psittacodus* of Agassiz).—This genus is exclusively represented by species from the oolitic slate of Stonesfield,—*e.g.*, *G. Bucklandi*, *G. Colei*, *G. Owenii.*

Genus Edaphodus, Egerton (including *Edaphodon* and *Passalodon* of Buckland).—The large *E. Sedgwickii* is from the greensand near Cambridge; the still larger *E. gigas* from the chalk of Kent and Sussex. The ichthyodorulite called *Psittacodus Mantelli* by Agassiz may be the dorsal spine of this species. Three species, including the *E. Bucklandi*, are found in the eocene of Bagshot and Bracklesham; and one species (*E. helveticus*) is from the mollasse of Switzerland.

The genus *Elasmodus*, Egerton, is exclusively represented by species,—*e. g.*, *E. Hunteri*, from the London clay of Sheppy.

Order III.—GANOIDEI.

Char.—Endo-skeleton in some osseous, in some cartilaginous, in some partly osseous and partly cartilaginous; exo-skeleton formed by enamelled bones; fins usually with the first ray a strong spine.

Sub-Order 1.—PLACOGANOIDEI.

(*Placodermes*,[1] Pander.)

Char.—Endo-skeleton cartilaginous, or retaining the notochord; head and more or less of the trunk protected by large ganoid, often reticulated, plates; heterocercal.

The last term signifies a form and structure of tail illustrated by fig. 42, and to be seen in the sharks, dog-fishes,

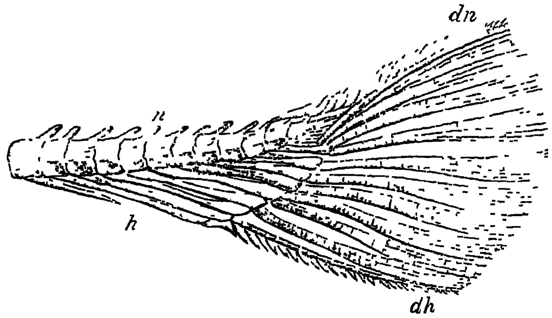

Fig. 42.

Heterocercal Tail (*Lepidosteus osseus*).

and sturgeons of the present day: it results from a prolongation of the vertebral column into the upper lobe *dn*, producing an unsymmetrical form of the caudal fin, which is contrasted with the symmetrical form of the same fin presented by most fishes of the present day, and illustrated by the skeleton of the perch, in art. ICHTHYOLOGY, fig. 10, p. 208, vol. xii., in which the vertebral column terminates at the middle of the base of the caudal fin. There are a few exceptional intermediate forms and structures of this fin.

The fossil remains of the singular fishes of the extinct order *Placoganoidei* were first discovered about 1813, in formations of the "old red" or Devonian age in Russia, and are preserved in museums at St Petersburg and Dorpat. The relation of these specimens to the class of fishes was first announced by Professor Asmuss,[2] and shortly after, the generic names *Asterolepis* and *Bothriolepis* were invented by Professor Eichwald,[3] to express certain modifications of the external surface of portions of the ganoid plates, subsequently recognised as constituting the buckler of the fore-part of the extinct fishes. In September 1840 Mr Hugh Miller submitted to the geological section of the British Association, at Glasgow, the first discovered specimens affording a recognisable idea of the form of one of these "old red" fishes, and for this form Professor Agassiz assigned the generic name *Pterichthys* (*pteron*, a wing, *ichthys*, a fish). Although, therefore, the term *Asterolepis* had been attached to a fragment of the cuirass of this fish a few months previously, yet, as no recognisable generic characters were associated with such name, and as *Asterolepis* has been applied also to another genus,—the *Heterostius* of Asmuss,—the example of British palæontologists will be here followed, in retaining the name *Pterichthys* for the genus. "Of all the organisms of the system," wrote the lamented Hugh Miller in his work on the *Old Red Sandstone*, "one of the most extraordinary, and the one in which Lamarck would have most delighted, is the *Pterichthys*, or winged fish, an ichthyolite which the writer had the pleasure of introducing to the acquaintance of geologists nearly three years ago (1840), but which he first laid open to the light about seven years earlier" (1833).

Genus PTERICHTHYS (fig. 43).—The head and the anterior half of the trunk are defended by ganoid plates,—*i. e.*, plates composed of a hard bone coated with enamel; those of the trunk forming a buckler composed of a back-plate (fig. 43) and breast-plate (fig. 44), articulated together at the sides. The rest of the trunk was defended by small ganoid scales, flexible, like scale-armour, and bore a small dorsal fin (fig. 43, *d*), and a terminal heterocercal fin, very rarely displayed

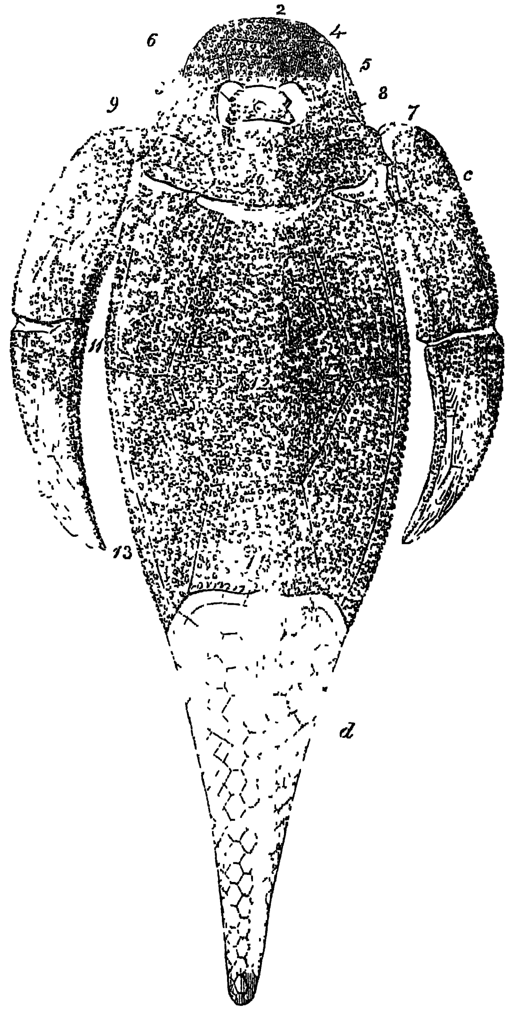

Fig. 43.

Pterichthys Milleri, dorsal surface (Devonian), after Pander.

in fossil specimens. The pectoral spines, *c*, are formed of ganoid material, like the buckler. The armour of the head, or helmet, appears to have been articulated by a moveable joint to the trunk-buckler. One of the few existing ganoid fishes (*Lepidosteus*) is remarkable for the degree in which the head moves upon the trunk. The component dermal plates of the helmet correspond in some measure with the position of the cranial bones in osseous fishes, but not sufficiently to sanction the application to them of corresponding names. They are indicated by figures in the cut 43: 2 is the front terminal or *rostral* plate; it is followed in the median line by four other plates in the following order:—4, *premedian*; 6, *median*; 8, *postmedian*; 10, *nuchal*; 3 is the *marginal*, and 7 the

[1] This term is used by other German writers as the equivalent of the PLACOIDEI of Agassiz, which answers to the *Plagiostomi* of Cuvier.

[2] *Bulletin Scient. par l'Acad. Imp. des Sciences de St Petersburg*, 1840, t. vi., p. 220.

[3] Ibid., t. vii., p. 78, communicated March 13th, 1840. Dr Fleming had recognized certain fossil scales as those of fishes in the "Old Red" of Fifeshire, in 1827.

postmarginal; 5 is the *prelateral*, and 9 the *postlateral*.

The dorsal shield of the trunk-cuirass is composed of two mid-plates and two on each side. 12 is the "*dorsomedian*," 14 the *post-dorsomedian;* 11 is the *dorsolateral*, 13 the *post-dorsolateral*. The ventral shield (fig. 44) consists of one mid-plate and three or four side-plates: 15 is the *pre-ventrolateral*, 19 the *ventrolateral*, 21 the *post-ventrolateral;* the small supplementary plate marked 17 is sometimes confluent with 19; 16 is the *ventromedian* plate; its margins are bevelled off and overlapped by the lateral plates.

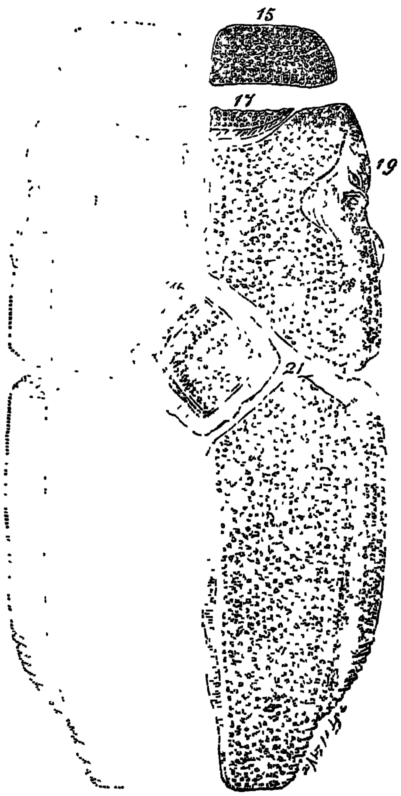

Fig. 44.

Pterichthys; Plastron or Ventral Shield. (Devonian), after Pander.

In the first-formed imperfect specimens of *Pterichthys*, the ventral shield was deemed the dorsal one. Sir P. Egerton has the merit of having first discerned its true position.

The pectoral spines are long and slender, and consist of two principal segments, both defended by finely tuberculated ganoid plates, like those of the head and trunk. From their form, they would seem to have served to aid the fish in shuffling along the sandy bottom or bed, if left dry at low-water. The fins attached to the flexible part of the body indicate a certain power of swimming, though not with any great rapidity. The jaws are small, and possess confluent denticles.

The type-species is the *Pterichthys Milleri;* others have been based upon proportions of the cuirass, of the pectorals, and the tail; all are from the "old red," and the great majority have been found in the Devonian strata of Ross-shire, Caithness, and other Scotch localities.

Genus CEPHALASPIS (*kephale*, head, *aspis*, buckler).—In this genus the posterior angles of the shield-shaped helmet are produced backwards in a pointed form, giving to the head the form of a "saddler's knife;" in other respects the genus closely resembles *Pterichthys*.

Mr D. Page has recently acquired specimens of *Cephalaspis* from Lanarkshire tile-stones, forming the base of the Devonian system, which show a dorsal fin, pectoral fins, and a large heterocercal fin, besides a well-marked capsule of the eye-ball.

Genus COCCOSTEUS (*kokkos*, berry, *osteon*, bone).—If a heterocercal fin were added in outline to the restoration of the fish of this genus, given in fig 45, a correct idea would be given of the "old red" fish, which, in the progress of its reconstruction, has suggested so many strange notions of its nature and affinities.

The helmet and cuirass are firmly united, and there is no trace of the jointed appendages, like pectoral fins, which characterize *Pterchthys*. The unprotected part of the trunk shows an ossification of the neural and hæmal spines, and of their appendages, the rays of a "dorsal" and "anal" fin; and by the analogy of *Cephalaspis*, the tail was most probably terminated by an unequal-lobed fin. The lower jaw is composed of two rami, loosely connected at the symphysis; so that, when displaced, as in fig. 46, 24, and as commonly in crushed fossil specimens, they gave the notion of the fish being provided with laterally-working jaws, like

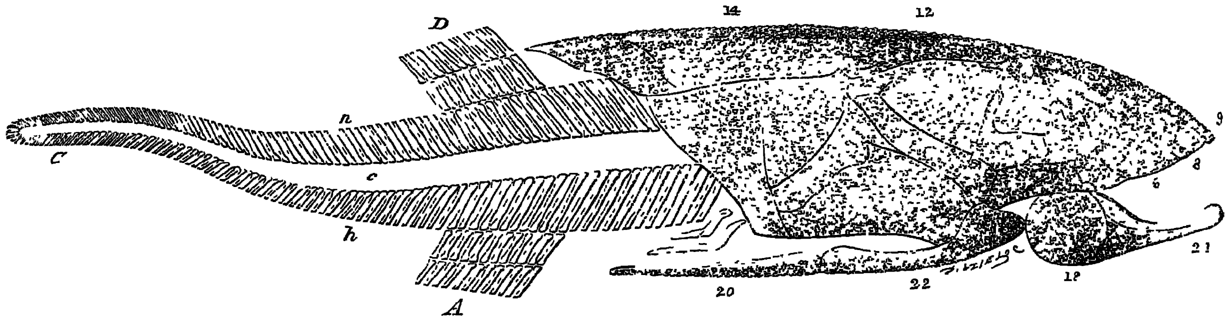

Fig. 45.

Coccosteus decipiens (Old Red Sandstone), after Pander.

those of the lobster. But, in reality, the jaw worked vertically upon a fixed upper jaw; both jaws being provided with from ten to twelve teeth on each side, anchylosed to the bone; each ramus of the jaw consisting of a premandibular (figs. 45 and 46, 24) and a postmandibular (fig. 45, 18) element.

An under-view of the cephalothoracic buckler of *Coccosteus*, according to Dr Pander's restoration, is given in fig. 46, showing the sutures of most of the cephalic plates, and the external surface of the plates of the plastron. 9, *Rostral plate;* 7, *premedian;* 5, *median;* 8, *prelateral;* 6, *lateral;* 16, *postmandibular;* 24, *premandibular;* 15, *pre-ventromedian;* behind the lozenge-shaped *ventromedian*, and on each side, are (22) the *pre-ventrolateral* and (23) the *post-ventrolateral*. The same figures mark the above plates in the side view (fig. 45), with the addition of (12) the *dorsomedian* and (14) the *post-dorsomedian*.

The blank space between the neural (n) and hæmal (h) spines of the fossil endo-skeleton indicates the position of the soft "notochord" (c), which has been dissolved away. The cylindrical gelatinous body, so called,—in Latin *chorda dorsalis*,—pre-exists to the formation of the bony bodies of the vertebræ in all vertebrate animals; and the development of those bodies seems never to have gone beyond this embryonal phase in any palæozoic fish; such fishes are accordingly termed "notochordal," retaining the notochord.

There are but two genera of existing fishes which manifest, when full grown, such a structure, associated with

Vertebrata. ossified peripheral elements of the vertebræ, viz., the *Protopterus* of certain rivers of Africa,[1] and the *Lepidosiren* of certain rivers of South America. Those fishes alone would,

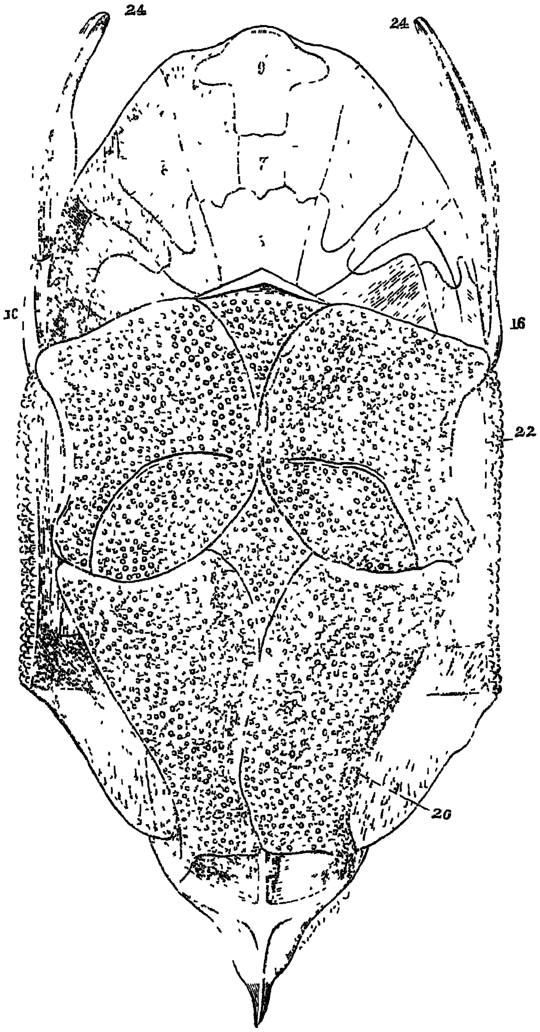

Fig. 46.
Cephalothoracic Buckler, ventral aspect, *Coccosteus decipiens* (Devonian).

if fossilized, present the appearance of the vertebral column shown in fig. 45, and which characterizes all the oolitic fossil ganoid fishes (see figs. 54 and 55). It is a strong illustration of a principle of "progression," this persistence in palæozic and most mezozoic fishes of an embryonic vertebral character, transitory in nearly all existing fishes.

The external "ganoid" surface of the buckler plates of *Coccosteus* is ornamented with small hemispherical tubercles; whence the generic name, signifying "berry-bone." The similarity of this ornamentation to that of the plates of the buckler in some *Tortoises*, led to the belief, when the coccosteal plates were first found, of their being evidence of the chelonian genus *Trionyx* in Devonian beds. Passing notions also got into print of the crustaceous affinities of *Coccosteus;* whence the trivial name of the type-species *decipiens*, or the "deceiving" *Coccosteus.*

Strange as seem the forms and structure of the placoganoid fishes of the "old red" period, there are not wanting existing species which throw much truer light on their nature than any existing *Chelonia* or *Crustacea.* The singular little family of "trunk-fishes" (*Ostracionidæ*) shows species in which the body is inclosed in a more or less quadrangular cuirass, composed of suturally-articulated ganoid plates, which are usually tuberculated on the external surface, and with the angles prolonged into spines in some species, like those of the helmet of *Cephalaspis.* The caudal part of the trunk protrudes from the back opening of the cuirass, as in *Coccosteus* and *Pterichthys*, and ossification of the endo-skeleton is incomplete. The species of this family are for the most part natives of seas of tropical or warm temperate latitudes. Vertebrata.

In another family of existing fishes, called "Siluroids," there are species in which the broad cranial bones, connate with dermal ossifications, form a helmet to the head, whilst one or two dermal spine-bearing bones combine to form the part called "buckler" by Cuvier.[2] In the genus *Doras*, the lateral line is armed with bony ganoid plates; and in *Callichthys*, these biserial plates are developed so as to incase the whole body. But generally, as in *Pimelodus*, the hinder muscular part of the trunk is undefended, as in *Coccosteus.* The ganoid plates of the head and back shields are fretted with rows or ridges of confluent tubercles, radiating from the centre to the circumference of the plate, whilst the inner surface is smooth, as in *Coccosteus* (fig. 46); and, moreover, the dorsal plate in existing Siluroids sends down a median ridge from its inner surface, like that from the "dorso-median" plate in *Coccosteus.* The point of resemblance to be mainly noticed, however, is the contrast furnished by the powerful armature of the head and back with the unprotected nakedness of the posterior portions of the creature—a point specially noticeable in *Coccosteus*, and apparent also, though in a lesser degree, in some of the other genera of the old red, such as the *Pterichthyes* and *Asterolepides.* "From the snout of the *Coccosteus* down to the posterior termination of the dorsal plate the creature was cased in strong armour, the plates of which remain as freshly preserved in the ancient rocks of the country as those of the *Pimelodi* of the Ganges on the shelves of the Elgin museum; but from the pointed termination of the plate immediately over the dorsal fin to the tail, comprising more than one-half the entire length of the animal, all seems to have been exposed, without the protection of even a scale; and there survives in the better specimens only the internal skeleton of the fish and the ray-bones of the fins. It was armed, like a French dragoon, with a strong helmet and a short cuirass; and so we find its remains in the state in which those of some of the soldiers of Napoleon's old guard, that had been committed unstripped to the earth, may be dug up in the future on the fatal field of Borodino, or along the banks of the Dwina or the Wap. The cuirass lies still attached to the helmet, but we only find the naked skeleton attached to the cuirass. The *Pterichthys* to its strong helmet and cuirass added a posterior armature of comparatively feeble scales, as if, while its upper parts were shielded with plate-armour, a lighter covering of ring or scale armour sufficed for the less vital parts beneath. In the *Asterolepis* the arrangement was somewhat similar, save that the plated cuirass was wanting. It was a strongly-helmed warrior in slight scale-armour; for the disproportion between the strength of the plated head-piece and that of the scaly coat was still greater than in the *Pterichthys.* The occipital star-covered plates are, in some of the larger specimens, fully three-quarters of an inch in thickness, whereas the thickness of the delicately-fretted scales rarely exceeds a line.

"Why this disproportion between the strength of the armature in different parts of the same fish should have obtained, as in *Pterichthys* and *Asterolepis*, or why, while one portion of the animal was strongly armed, another portion

[1] See *Linnæan Transactions*, vol. xviii.; and *Proceedings of the Linnæan Society*, April 2, 1839.

[2] *Histoire des Poissons*, tom. xii.

Vertebrata.

should have been left, as in *Coccosteus*, wholly exposed, cannot of course be determined by the mere geologist. His rocks present him with but the fact of the disproportion, without accounting for it. But the natural history of existing fish, in which, as in the *Pimelodi*, there may be detected a similar peculiarity of armature, may perhaps throw some light on the mystery. In Hamilton's *Fishes of the Ganges*, the habitats of the various Indian species of *Pimelodi*, whether brackish estuaries, ponds, or rivers, are described, but not their characteristic instincts. Of the *Silurus*, however, a genus of the same great family, I read elsewhere that some of the species, such as the *Silurus Glanis*, being unwieldy in their motions, do not pursue their prey, which consists of small fishes, but lie concealed among the mud, and seize on the chance stragglers that come in their way. And of the *Pimelodus gulio*, a little strongly-helmed fish with a naked body, I was informed by Mr Duff, on the authority of the gentleman who had presented the specimens to the Museum, that it burrowed in the holes of muddy banks, from which it shot out its armed head, and arrested, as they passed, the minute animals on which it preyed. The animal world is full of such compensatory defences; there is a half-suit of armour given to shield half the body, and a wise instinct to protect the rest. Now it seems not improbable that the half-armed *Coccosteus*, a heavy fish, indifferently furnished with fins, may have burrowed, like the recent *Silurus Glanis* or *Pimelodus gulio*, in a thick mud, of the existence of which in vast quantity, during the times of the old red sandstone, the dark Caithness flagstones, the fœtid breccia of Strathpeffer, and the gray stratified clays of Cromarty, Moray, and Banff unequivocally testify; and that it may have thus not only succeeded in capturing many of its light-winged contemporaries, which it would have vainly pursued in open sea, but may have been enabled also to present to its enemies, when assailed in its turn, only its armed portions, and to protect its unarmed parts in its burrow."[3]

Sub-Order 2.—LEPIDOGANOIDEI.

FAMILY I.—DIPTERIDÆ.

This family includes a few heterocercal fishes with a double anal as well as dorsal fin. The head is large and flattened; the teeth subequal; the scales perforated by small foramina; the notochord persistent.

In the genus *Dipterus* (fig. 47), the two dorsals, *d* 1, *d* 2, are opposite the two anals, *a* 1, *a* 2: the ventrals, *v*, are in

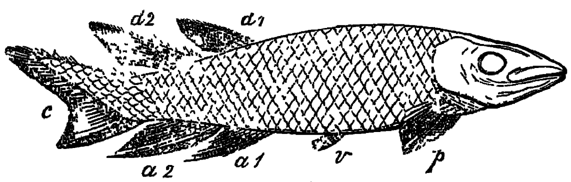

Fig. 47.
Dipterus macrolepidotus (Devonian).

advance of the first anal and first dorsal. The *Dipterus macrolepidotus* is characterized by the large size of its scales. Its remains are found in the old red sandstone of many localities of Scotland and England.

In the allied genus *Diplopterus* the vertical fins are opposite, but the dorsals are wider apart, and the teeth are larger and fewer. Four species have been recognised in the "old red" of Gamrie, Orkney, and Lethenbar, Ross-shire. Two species occur in the carboniferous series.

In the genus *Osteolepis* the vertical fins are alternate in position, the first dorsal being near the middle of the back. All the species of this genus are from the "old red."

Vertebrata.

FAMILY II.—ACANTHODII.

The species of this family are characterized by their very small scales: they are heterocercal and notochordal. There is a strong spine in front of each fin. The head is large; the orbits approximate; the mouth wide, and opening obliquely upwards, so that they have somewhat the aspect of the *Uranoscopi*. The principal genera are from the old red sandstone, and are as follows:—*Cheiracanthus*, with a single dorsal situated in front of the anal; *Cheirolepis*, in which the dorsal is situated behind the anal; and *Diplacanthus* (fig. 48), in which there are two dorsals.

The *Diplacanthus striatus* is found in the "old red" of Cromarty. In fig. 48, as in the other figures, *p* is the pectoral fin, *d* the dorsal, *v* the ventral, *a* the anal, and *c* the

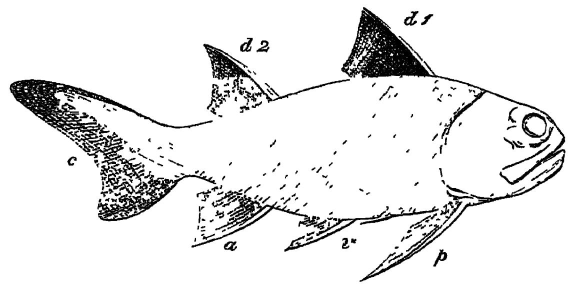

Fig. 48.
Diplacanthus striatus.

caudal. In this species the upper lobe of the caudal is much prolonged. The fin-spines in the *Acanthodii* were, like those of the recent dog-fish (*Spinax*), simply imbedded in the flesh, with their base, as it were, unfinished, not provided, as in the Siluroids and other modern bony fishes, with a joint-structure. Some species of *Acanthodii* existed in the seas of the carboniferous period.

FAMILY III.—CŒLACHANTHI.

The species of this family are characterized by the hollowness of the rays or spines; whence the name. The caudal fin has a peculiar structure, the vertebral column being continued into and beyond its middle part, supporting a kind of slender appendage between the two normal lobes. The species of the genus are most abundant in the Devonian and carboniferous formations; but some occur in oolitic and even cretaceous beds; but all became extinct before the tertiary epoch.

Glyptolepis had a heterocercal tail, with rounded scales, smooth externally, and with radiating compartments internally. The *G. microlepidotus*, of which a magnified view of some scales is given in fig. 49, occurs in the old red sandstone of Scotland and England.

FAMILY IV.—HOLOPTYCHIIDÆ.

The type-genera of this family were first recognised and characterized by the fossil scales, under the name *Holoptychius* (Ag.), and by the fossil teeth, under the name *Rhizodus* (Ow.) They include species which have left their remains in the "old red" and the coal measures. They are nearly allied to the Cœlacanthians, having, like them, but partially ossified bones and spines, the interior of which retained their primitive gristly state, and appear hollow in the fossils. The head was defended by large externally sculptured and tuberculate ganoid plates. The teeth consist of two kinds,—small

Fig. 49.
Glyptolepis microlepidotus (Devonian).

[1] Hugh Miller, *Rambles of a Geologist*, p. 288.

serial teeth, and large laniary teeth,—at long intervals; both kinds showing the "labyrinthic" structure[1] at their base, which is anchylosed to the jaw-bone. Large fossil teeth, with the more complex "dendritic" disposition of the tissues, characterize a genus (*Dendrodus*), most probably of the Holoptychian family.

The generic term *Rhizodus* is now retained for the *Holoptychians* of the coal measures which have more robust and obtuse serial teeth, and longer, sharper, and more slender laniaries, exemplified by the *R. Hibberti*.[2] Species of true *Holoptychius*,—*e.g.*, *H. giganteus* (Ag.), *H. nobilissimus* (Ag.), occur in the old red sandstone. A most noble specimen of the latter species, 2 feet 6 inches in length, discovered in the old red sandstone at Clashbinnie, near Perth, is now in the palæontological series of the British Museum. It is chiefly remarkable for the size and bold sculpturing of the ganoid scales (fig. 50).

Fig. 50.
Scale of *Holoptychius nobilissimus* (Devonian), ½ nat. size.

"The amount of design exhibited in the scales of some of the more ancient Ganoids,—design obvious enough to be clearly read,—is very extraordinary. A single scale of *Holoptychius nobilissimus*, fast locked up in its red sandstone rocks, laid by, as it were, for ever, will be seen, if we but set ourselves to unravel its texture, to form such an instance of nice adaptation of means to an end as might of itself be sufficient to confound the atheist. Let me attempt placing one of these scales before the reader in its character as a flat counter of bone, of a nearly circular form, an inch and a half in diameter, and an eighth part of an inch in thickness; and then ask him to bethink himself of the various means by which he would impart to it the greatest possible degree of strength. The human skull consists of two tables of solid bone, an inner and an outer, with a spongy cellular substance interposed between them, termed the *diploë*; and such is the effect of this arrangement, that the blow which would fracture a continuous wall of bone has its force broken by the spongy intermediate layer, and merely injures the outer table, leaving not unfrequently the inner one, which more especially protects the brain, wholly unharmed. Now, such also was the arrangement in the scale of the *Holoptychius nobilissimus*. It consisted of its two well-marked tables of solid bone, corresponding in their dermal character, the outer to the cuticle, the inner to the true skin, and the intermediate cellular layer to the *rete mucosum*; but bearing an unmistakeable analogy also, as a mechanical contrivance, to the two plates and the *diploë* of the human skull. To the strengthening principle of the two tables, however, there were two other principles added. Cromwell, when commissioning for a new helmet, his old one being, as he expresses it, "ill set," ordered his friend to send him a "*fluted pot*,"—*i.e.*, a helmet ridged and furrowed on the surface, and suited to break, by its protuberant lines, the force of a blow, so that the vibrations of the troke would reach the body of the metal deadened and flat. Now, the outer table of the scale of the Holoptychius was a "fluted pot." The alternate ridges and furrows which ornamented its surface served a purpose exactly similar with that of the flutes and fillets of Cromwell's helmet. The inner table was strengthened on a different but not less effective principle. Now, the inner table of the scale of the Holoptychius was composed on this principle, of various layers or coats, arranged the one over the other, so that the fibres of each lay at right angles with the fibres of the others in immediate contact with it. In the inner table of one scale I reckon nine of these alternating, variously-disposed layers; so that any application of violence, which, in the lath-splitter, would *run lengthwise along the grain* of four of them, would be checked by the *cross grain* in five. In other words, the line of the *tear* in five of the layers was ranged at right angles with the line of the *tear* in four. There were thus in a single scale, in order to secure the greatest possible amount of strength,—and who can say what other purposes may have been secured besides?—three distinct principles embodied, the principle of the two tables and *diploë* of the human skull, the principle of those of the variously-arranged coats of the human stomach, and the principle of Oliver Cromwell's "fluted pot." There have been elaborate treatises written on those ornate flooring-tiles of the classical and middle ages, that are occasionally dug up by the antiquary amid monastic ruins, or on the sites of old Roman stations; but did any of them ever tell a story half so instructive or so strange as that told by the incalculably more ancient ganoid *tiles* of the palæozoic and secondary period?"[4]

Such are some of the forms and structures of fishes that swam in the seas from which were deposited the sediment that has hardened into the "old red sandstones" of Great Britain, Russia, and other parts of the world. And in this process of consolidation the carcases of the fishes entombed in the primæval mud have had their share. For, just as a plaster-cast boiled in oil derives greater density and durability from that addition, so the oily and other azotized and ammoniacal principles of the decomposing fish operated upon the immediately surrounding sand so as to make it harder and more compact than the sediment not reached by the animal principles. Accordingly it has happened that in the course of the upheaval and disturbance of old red strata, parts of it, broken up and exposed to the action of torrents, have been reduced to detritus, and washed away, with the exception of certain nodules, generally of a flattened elliptic form, which are harder than the surrounding sandstone. Such nodules form the bed of many a mountain stream in "old red sandstone" districts of Scotland. If one of these nodules be cleft by a smart and well-applied stroke of the hammer, the cause of its superior density will be seen in a more or less perfect specimen of the fossilized remains of some animal, most commonly a fish.

But the placoganoid and ganoid, heterocercal and notochordal, fishes of the Devonian epoch existed in such vast shoals in certain favourable inlets, that the whole mass of the sedimentary deposits has been affected by the decomposing remains of successive generations of those fishes. The Devonian flagstones of Caithness are an instance. They owe their peculiar and valuable qualities of density, tenacity, and durability wholly to the dead fishes that rotted in their primitive constituent mud. In no other part of the world, perhaps, can the builder set a large flagstone on its edge with assurance of its holding long together in that position. A great proportion of the county of Caithness formed, before its upheaval, the bottom of what may truly be termed a "piscina mirabilis." Yet there are minds, one at least,[5] who, cognisant of the wonderful structures of the extinct Devonian fishes—of the evidence of design and adaptation in their structures—of the altered nature of the sediment surrounding them, and its dependence on the admixture of the decomposing and dissolved soft parts of the old fish—would deliberately reject the conclusions which healthy human reason must, as its Creator has constituted it, draw from such evidences of His operations. There are now individuals, one at least, who prefer to try to make it be believed that God had recently, and at once, called into being all these phenomena; that the fossil bones, scales, and teeth, had never served their purpose,—had never been recent,—were never truly developed, but created fossil; that the

[1] See art. ODONTOLOGY, vol. xvi., p. 412, fig. 12. [2] Ibid., p. 413, fig. 14. [3] Owen's *Odontography*, vol. ii., p. 75, pls. 35 and 36.
[4] Hugh Miller, *Rambles of a Geologist*, p. 284. [5] See *Omphalos*, by P. H. Gosse, 8vo, 1858.

creatures they simulate never actually existed; that the superior hardness of the inclosing matrix was equally due to primary creation, not to any secondary cause; that the geological evidences of superposition, successive stratification, and upheaval were, equally with the palæontological evidences, an elaborate design to deceive and not instruct! Surely, on such hypothesis, the workmanship must be that of the father of lies, not of the Author of Truth, and the imaginer of such hypothesis must be a Manichean at heart.

The sub-order of Placoganoids, so richly represented in the Devonian epoch, disappears in the carboniferous one; the Ganoids, with rhomboid scales, increase in number. These are characteristically represented by the genus *Palæoniscus*, species of which range throughout the carboniferous and Permian beds. *Palæoniscus* (fig. 51) is characterized by the heterocercal tail and moderate-sized fins, the dorsal, *D*, being single, and opposite the interval between the anal, *A*, and ventral, *V*, fins: each fin has an anterior spine.

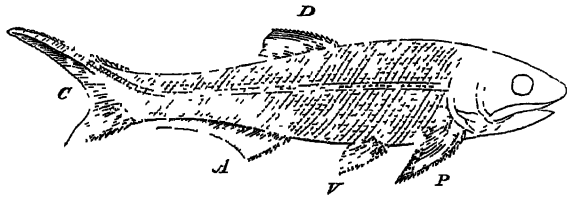

Fig. 51.
Palæoniscus (Permian).

The fore-part of the head is obtuse; the jaws armed with numerous small close-set teeth, or *en brosse*. The ganoid scales are rhomboidal: in the *Palæonisci*, from the coal formations at Burdie House, near Edinburgh, their outer surface is striate and punctate; *e.g.*, in *P. ornatissimus*, *P. striatus*; but in the *Palæonisci* of other British localities, and of the continental and American coal formations, the scales are smooth; *e.g.*, in *P. fultus*, from North America, *P. Duvernoyi* and *P. minutus*, from the coal beds of Munster-Appel. In the *Palæonisci* from the Permian copper schales and zechstein, the scales are striate or punctate. The *Palæoniscus Freieslebeni* is the most common, and was the first recognised species of the genus.

Amblypterus, with a geological range like that of *Palæoniscus*, differs in its shorter and deeper tail, and larger body-fins, which are devoid of anterior spines. In fig. 52 *a* indicates the outer surface of parts of two series of the rhomboidal ganoid scales; and *b* the inner surface of two scales, showing the ridge produced at one end into a projecting peg, which fits into a notch of the next scale, in the way that tiles are pegged together in the roof of a house. The species affording the above is the *Amblypterus striatus* from the coal-formations at Newhaven.

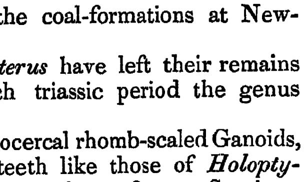

Fig. 52.
Scales of *Amblypterus striatus* (Carboniferous).

Several species of *Amblypterus* have left their remains in the muschelkalk, at which triassic period the genus seems to have passed away.

Magnificent species of heterocercal rhomb-scaled Ganoids, with large dispersed laniary teeth like those of *Holoptychius*, sometimes of a size rivalling those of great Saurians, for which they have been mistaken, have left their remains in the coal strata at Carluke, near Glasgow, and other localities, and constitute the genus *Megalichthys* of Agassiz. The head is defended by strong ganoid plates, of a beautiful polish; the trunk-scales are usually granulate exteriorly.

The sub-order *Pycnodontes* is represented in the carboniferous strata by the heterocercal genus *Platysomus* (fig. 53), and by the species *P. parvulus*, which has been found

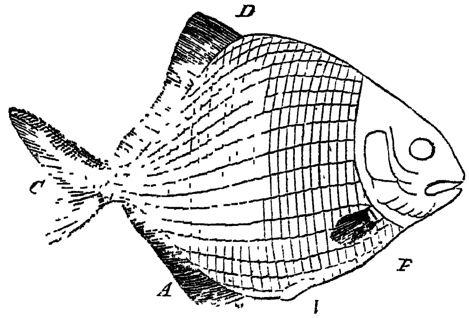

Fig. 53.
Platysomus gibbosus (zechstein of Mansfeld).

n that formation at Leeds; but most of the pycnodont fishes belong to the mezozoic period.

Pygopterus, *Acrolepis*, *Eurynotus*, *Elomichthys*, *Plectrolepis*, *Graptolepis*, *Orognathus*, *Pododus*, *Acanthodes*, and *Diplopterus* are carboniferous genera of Ganoids, with rhomboid scales. *Cœlacanthus*, *Isodus*, *Phyllolepis*, *Hoplopygus*, *Uronemus*, *Colonodus*, *Centrodus*, *Asterolepis*, *Psammosteus*, and *Osteoplax*, are genera of Ganoids with rounded scales, represented by species in carboniferous strata.

Of the above-named genera, *Acrolepis*, *Pygopterus*, *Palæoniscus*, *Platysomus*, and *Cœlacanthus*, continue to be represented in Permian beds; in which also are found species of the ganoid genera *Dorypterus*, *Holacanthodus*, and *Globulodus*, if the teeth on which the latter is based be not those of *Platysomus*.

The formations of the mezozoic or secondary periods give evidence of the full development of the ganoid order. In the lowest or "triassic" division this order is still represented by heterocercal and notochordal species belonging to some of the genera of the Permian period, as, *e.g.*, *Cœlacanthus*, *Amblypterus*, and *Palæoniscus*. The genus *Placodus*, a supposed pycnodont fish of the muschelkalk, has been shown to be a conchivorous Saurian.[1] In the oolitic division the heterocercal Ganoids are almost completely superseded by homocercal genera, which now, for the first time, appear on the stage of life; but the ossification of the endo-skeleton is still incomplete. In the cretaceous series the Teleostian, or well-ossified bony fishes, are numerous; and here also first are seen fishes with the flexible "cycloid" or "ctenoid" scales, and of genera which continue to be represented by living species.

Of 33 genera of fishes in the lias, 4 only were represented in older strata, while the rest extend into the upper oolitic beds. Of these, 19 genera are Ganoids with rhomboid scales, and two (*Leptolepis* and *Gyrosteus*) have rounded scales. The sub-order *Sturionii*, represented by the sturgeons of the present seas, makes its first appearance in the lias, under the generic form of *Chondrosteus*, which has recently received a full description and illustration in a memoir communicated by Sir P. Egerton to the Royal Society of London.[2] In this it is shown "that *Chondrosteus*, though essentially sturionian, yet evidences a transitional form between the sturgeons and more typical Ganoids; that its food was similar to that of the existing members of the family, but that it was procured in a tranquil sea, rather than in the tumultuous waters frequented by sturgeons at the present time."

[1] Owen, in *Phil. Trans.* 1858, p. 169.

[2] *Proceedings of the Royal Society*, April 20, 1858.

Sub-Order 3.—PYCNODONTES.

The name of this group of ganoid fishes refers to the form of the greater proportion of the teeth, especially those attached to the palate and hind alveolar part of the lower jaw: the few anterior teeth are small and sub-prehensile; but the whole dentition bespeaks fishes adapted to feed on small testaceous and crustaceous animals.

The Pycnodonts were for the most part deep-bodied fishes, symmetrically compressed from side to side. They were notochordal; a few of the earlier forms (*Platysomus, e.g.*, fig. 53) were heterocercal, but the majority of the sub-orders were homocercal.

In the lias, most beautiful fossil fishes of this group are found, which were referred by Bronn to the genus *Tetragonolepis*, and by Agassiz to the lepidoid sub-order. Sir P. Egerton has, however, shown that the dentition is truly "pycnodont," having a very close resemblance to that of *Microdon*, but with the masticatory apparatus smaller in proportion to the size of the fish. The scales, moreover, instead of being articulated by interlocking pegs and sockets, as in fig. 52, are joined in a peculiar way, which Sir P. Egerton describes as follows:—"Each scale bears upon its inner anterior margin a thick solid bony rib, extending upwards beyond the margin of the scale, and sliced off obliquely above and below, on opposite sides, for forming splices with the corresponding processes of the adjoining scales. These splices are so closely adjusted, that without a magnifying power, or an accidental dislocation, they are not perceptible. When *in situ*, and seen internally, these continuous lines decussate with the true vertebral apophyses, and cause the regular lozenge-shaped pattern so characteristic of the pycnodont family."[1]

The Pycnodonts so characterized are further distinguished from the closely-resembling lepidoid genus *Dapedius*, by having the small anterior teeth conical and single-pointed, instead of being bifurcate; and although this character is subject to occasional variations, nevertheless, on taking a comprehensive view of all the dapedioid species, it seems to have been sufficiently constant to warrant the continuance of the separation of the group into the unicuspid and bicuspid species. And Sir P. Egerton has accordingly proposed to apply the generic terms *Æchmodus* (from αἰχμή, *a point*, and ὀδοὺς, *a tooth*),[2] for the unicuspid and pycnocodont species, formerly termed *Tetragonolepis*, and to continue the name *Dapedius* for the bicuspid and unequivocally lepidoid homocercal deep-bodied Ganoids, many beautiful species of which are found in the lias.

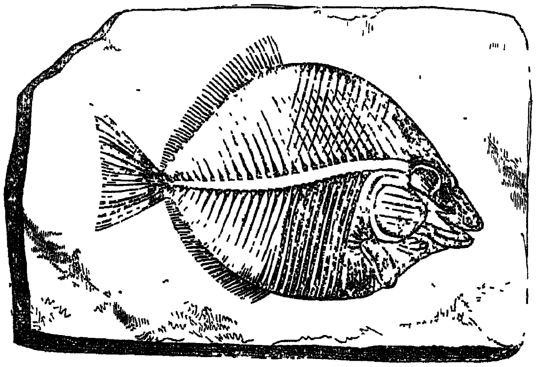

Fig. 54.
Pycnodus rhombus (Upper Oolites).

Genus Pycnodus (fig. 54).—The type-genus of this sub-order is characterized by the large size of the round flat crowned teeth, which cover the broad jaws as by a pavement of from three to five rows;[3] at the fore-part of the jaws are two or more trenchant incisive teeth both above and below.

The oblique inner processes of the scales, and which in some species appear as distinct dermal ossicles decussating the neural spines, are limited in *Pycnodus* to the space between the occiput and the dorsal fin (fig. 54).

This species of *Pycnodus* abound in the oolitic formations above the lias: the one figured (*P. rhombus*) is from a calcareous deposit, so charged with animal remains as to be fœtid, at Torre d'Orlando, near Naples. Species of *Pycnodus* (*P. cretaceous, e.g.*) occur in the chalk of Kent; and one species (*P. toliapicus*) has left its remains in the eocene clay of Sheppy. Some teeth from German miocene have been referred to this genus; but at this period, if not at the earlier tertiary one, *Pycnodus* became extinct.

Sub-Order 4.—LEPIDOSTEIDÆ, Muller.

Char.—Ganoids with rhomboid scales and conical teeth; a single dorsal.

Family I.—Sauroidei, Agassiz.

Char.—Some of the teeth much larger than the rest, and laniariform.

Genus Caturus.—In this genus the jaws are armed with close-set, large, conical teeth; the scales are delicate; all the species are homocercal and notochordal (fig. 55). The

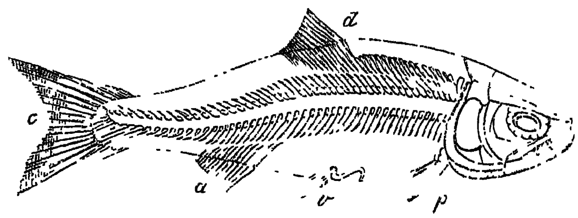

Fig. 55.
Caturus furcatus (Oolite, Solenhofen).

dorsal, *d*, is opposite the ventral, *v*, all the fins are of moderate size. One species of *Caturus* (*C. Bucklandi*) is from the lias; but the majority, like *C. furcatus*, are from the lithographic slates of Solenhofen. The most recent known species (*C. similis*) is from the chalk of Kent.

Pachycormus, Saurostomus, Sauropsis, Thryssonotus, and *Eugnathus*, are among the well-marked genera of the Sauroid family. It is represented at the present day by the North American genus *Lepidosteus;* but in this fish not only is the notochord converted into bony vertebral bodies, but these are united by ball-and-socket joints.

Sub-Order 5.—CYCLOGANOIDEI.

Family I.—Leptolepidæ.

The Ganoids of this family are homocercal, and have rounded scales. In the type-genus (*Leptolepis*, fig. 56), the scales are extremely thin, yet a fine layer of ganoin may be discovered in them. The teeth are minute and *en brosse*, with two of larger size in front of the mouth. It has not been determined whether the notochord is ossified; but traces of distinct vertebral bodies appear to the writer to be discernible in some specimens. Species of *Leptolepis* range from the lias to the calcareous slates of Eichstadt.

[1] *Proceedings of the Geological Society*, May 1853, p. 276.
[2] Ibid., May 1854, p. 367.
[3] For the disposition of these teeth on the palate, see Owen's *Odontography*, vol. i., pl. 34, figs. 1 and 2; and for their microscopic structure, ibid., p. 71, pl. 33.

They are very common in the lithographic slates of Solenhofen and Pappenheim.

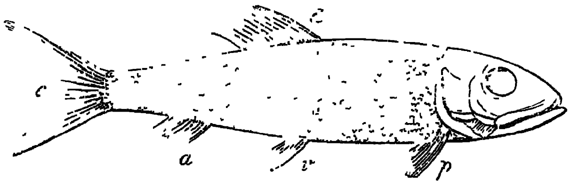

Fig. 56.
Leptolepis sprattiformis (Oolite, Solenhofen).

Genus Macropoma.—Fine specimens of homocercal ganoid fishes, with rounded scales, sculptured externally, as in fig. 57, have been discovered in the chalk formations of Kent and Sussex. They have been referred by Agassiz to the genus called *Macropoma*, significative of the large size of the gill-cover, and to the cœlacanthal family; but traces of vertebral bodies are apparent in some specimens. Casts of the "interior" of the alimentary canal, showing impressions of a broad spiral valve, are preserved in certain specimens in the British Museum. One species (*M. Egertoni*) is from the Speeton clay; the other (*M. Mantelli*) from the chalk.

Fig. 57.
Macropoma Mantelli.
(Chalk.)

In the tertiary division the ganoid order rapidly diminishes, and its place is taken by fishes with better ossified internal skeletons, and with thinner, more flexible, and usually soluble scales. The gills are supported on bony arches, and are protected by branchiostegal rays, and by an operculum or gill-cover. The aortic bulb is provided with but two valves; and the optic nerves decussate. For this group, including the majority of existing fishes, and of those which made their appearance during the tertiary period, Müller proposed the name "Teleostei," which almost corresponds with the "osseous fishes" of Cuvier. After the full and accurate illustration of this great group in the article Ichthyology, little is required to be added by way of illustration from extinct species.

Order IV.—ACANTHOPTERI.

Sub-Order 1.—CTENOIDEI.

Char.—Endo-skeleton ossified; exo-skeleton as ctenoid scales (fig. 58); fins with one or more of the first rays unjointed or inflexible spines; ventrals in most beneath or in advance of the pectorals; swim-bladder without air-duct.

Of this order may be given two genera, both of which are now extinct. One (*Semiophorus*) belongs to the chetodont family;[1] the other (*Smerdis*) to the Percoids.[2]

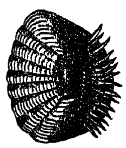

Fig. 58.
Scale of *Perca* (Recent).

The genus *Semiophorus*, Ag. (fig. 59), is represented exclusively by extinct species peculiar to the tertiary deposits at Monte Bolca. It is characterized by the extreme height or prolongation of the anterior part of the dorsal fin, D, and for the correlative elongation of the slender pointed ventral fins. The anal fin, A, is much shorter than the dorsal. Owing to the soluble nature of the scales, and to the well-ossified skeleton, the fossils of this, as of most other tertiary fishes, are exemplified by the vertebral column and skull more than by the skin.

Sub-Order 2.—CYCLOIDEI.

Genus Smerdis.—The species composing this genus are of small size, and are wholly extinct; they likewise are chiefly met with in the tertiary ichthyolite beds of Monte Bolca; but some (*e.g.*, the *Smerdis minutus*, fig. 60) are

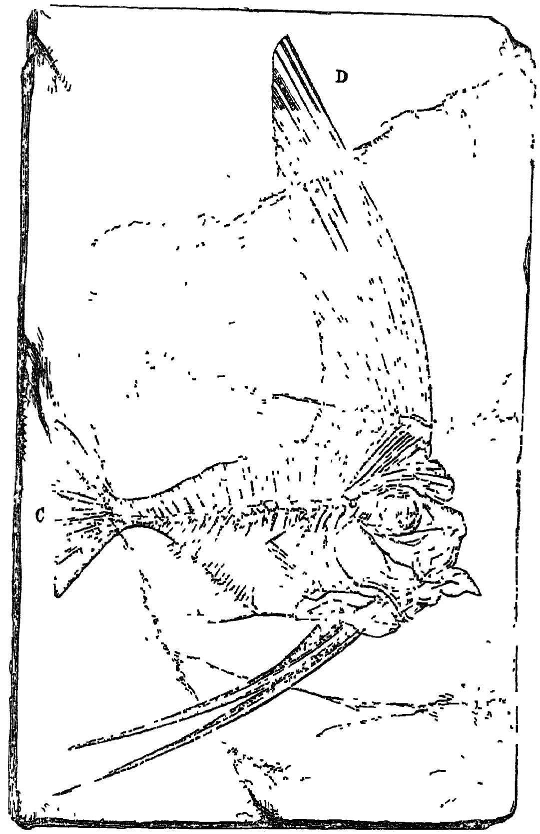

Fig. 59.
Semiophorus velicans (Monte Bolca).

from eocene deposits in France. In all the species the first suborbital or lacrymal bone is stongly dentate, as is

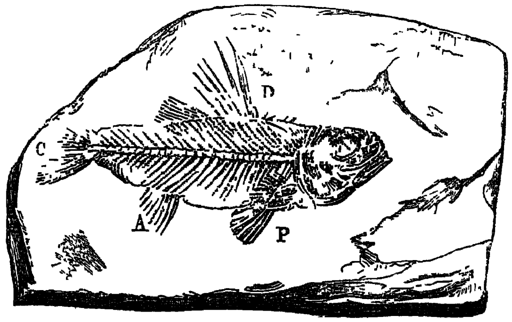

Fig. 60.
Smerdis minutus (Gypsum of Provence).

also the preoperculum; but this has no spine at the angle. The operculum terminates behind by a rounded prominence. There are two dorsals. The scales are minute, but are occasionally preserved. Those of *Smerdis minutus* present, under a magnifier, the structure shown in fig. 61.

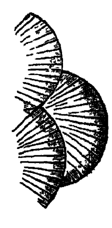

Fig. 61.
Scales of *Smerdis minutus* (mag.)

In the article Ichthyology, figures are given of the two kinds of existing sword-fish (*Xiphias*, fig. 112; and *Histiophorus*, fig. 113); in the former the sword-like prolongation of the confluent premaxillaries is flattened, in the latter it is rounded.

[1] See art. Ichthyology, pp. 299–232.

[2] Ibid., p. 273.

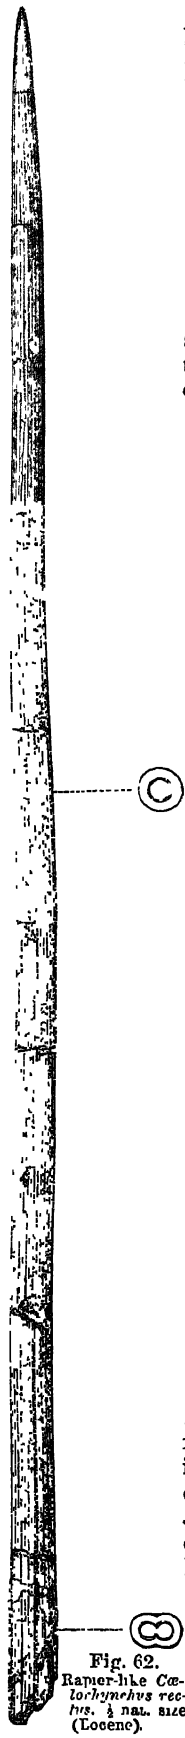

Fig. 62.
Rapier-like *Cœlorhynchus rectus*. ½ nat. size (Eocene).

Fossil remains of a rounded rapier-like sword, but much longer and more slender than in the existing *Histiophorus*, have been found in the eocene clay at Sheppy and Bracklesham. They are referred to an extinct genus of the xiphioid family by Agassiz, called *Cœlorhynchus*, or "hollowbeak." The most perfect specimen hitherto found is figured in fig. 62, of half the natural size. It forms part of the instructive collection of Captain Le Hon at Brussels. The upper transverse section shows the single cavity at the middle of the rostrum; and the lower section shows the double or divided cavity near its base.

Order V.—Anacanthini.

Char.—Endo-skeleton ossified; exo-skeleton in some as cycloid, in others as ctenoid scales; fins supported by flexible or jointed rays; ventrals beneath the pectorals, or none; swim-bladder without air-duct.

Family.—Pleuronectidæ.

(*Flat-Fishes.*)

In this family the symmetrical form is lost, and both eyes are on one side of the head. Species of still existing genera of this much-modified family have been found in tertiary deposits. The little turbot (*Rhombus minimus*, *e.g.*, fig. 63) occurs in the tertiary deposits of Monte Bolca. An equally extinct species of sole (*Solea antiqua*) has been found in tertiary marls near Ulm.

Fossil fishes of the cod, mullet, carp, salmon, and herring genera, are found in the tertiary formations, but are distinct from all known species.

The Ganoids are reduced to the genera *Lepidosteus* and *Acipenser*, but may have been represented by the palates with crushing teeth, to which the names *Pisodus*[1] and *Phyllodus*[2] have been given. With respect to the fishes of the tertiary period, "they are so nearly related," says Agassiz, "to existing forms, that it is often difficult, considering the enormous number (above 8000) of living species, and the imperfect state of preservation of the fossils, to determine exactly their specific relations. In general I may say that I have not yet found a single species which was perfectly identical with any marine existing fish, except the little species *Mallotus villosus*, which is found in the nodules of clay of unknown geological age in Greenland."

For a list of the genera and species of fossil fishes known at the date of publication, reference may be made to the article Fossil Ichthyology. Since that was written, it has been determined that the "schists of Glaris" and of "Monte Bolca," belong to the eocene tertiary period.

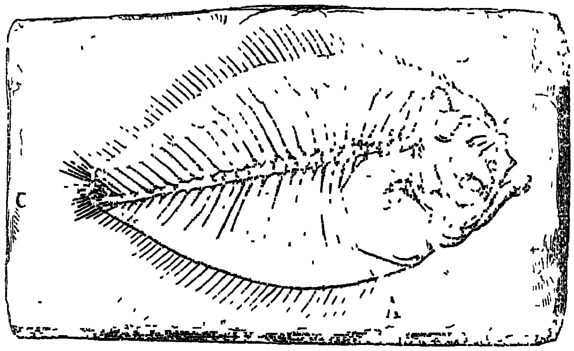

Fig. 63.

Rhombus minimus (Monte Bolca).

We cannot, from present knowledge, assign to any past period of the earth's history a characteristic derived from a fuller and more varied development of the entire class of fishes than has since been manifested, nor predicate of the present state of the class that it has degenerated in regard either to the number, bulk, powers, or range of modifications of the piscine type. A retrospect of the genetic history of fishes imparts an idea rather of mutation than of development, to which the class has been subject in the course of geological time. Certain groups, now on the wane, have existed in plenary development, as, *e.g.*, the ganoid order in the mezozoic period, and the cestraciont form of Plagiostomes in both palæozoic and mezozoic times.

As to the variety of the forms of fishes, seeing that the earth yields no evidence of Ctenoids or Cycloids[3] anterior to the cretaceous epoch, yet still retains living representatives of both Ganoids and Placoids, the present would appear to be the culminating period in the development of fishes, in respect of the number of ordinal forms or modifications of the class. It represents, however, rather a period of mutation of the piscine character, depending upon the progressive assumption of a more special piscine type, and progressive departure from a more general vertebrate type. The Scomberoids, as fishes, are at the head of the piscine modification of the vertebrate type. And as the retention of general vertebrate characters implies closer affinity with the proximate cold-blooded class, so a higher character of organization may be predicated of the palæozoic Placoids and Ganoids than of the Ctenoids and Cycloids forming the great bulk of the class at the present day. The comparative anatomist dissecting a Shark, a Polypterus, or a Lepidosteus, would point to the structures of the brain, heart, generative organs, and in the last two genera to the air-bladder, as being of a higher or a more reptilian character than the corresponding parts would present in most other fishes. But the palæontologist would point to the persistent notochord, and to the heterocercal tail in palæozoic and many mezozoic fishes, as evidence of an "arrest of development," or of a retention of embryonic characters in those primæval fishes.

No class of animals is more valuable in its application to the great point now mooted by the Uniformitarians and Progressionists of the present day than that of fishes; for they are exempt from the attack of the Uniformitarian

2 Ibid., p. 139, pl. 47, figs. 1 and 2.

3 See for the explanation of these terms in the system of Agassiz the article Fossil Ichthyology, *Ency. Brit.*, vol. xii.

on the score of the defect of negative evidence, to which attack conclusions from the known genetic history of air-breathing animals are open. Many creatures living on land may never be carried out to sea; but marine deposits may be expected to yield adequate evidence for general conclusions as to the character of the vertebrate animals that swarmed in the seas precipitating such deposits.

One other conclusion may be drawn from a general retrospect of the mutations in the forms of the fishes at different epochs of the earth's history,—viz., that those species, such as the nutritious cod, the savoury herring, the rich-flavoured salmon, and the succulent turbot, have greatly predominated at the period immediately preceding and accompanying the advent of man; and that they have superseded species which, to judge by the bony Garpikes (*Lepidosteus*), were much less fitted to afford mankind a sapid and wholesome food.

ICHNOLOGY.[1]

In entering upon the genetic history of the class of reptiles, we have to inquire, as in that of fishes, in what period of the earth's history the class was introduced, and under what forms; at what period it attained its plenary development, in regard to the size, grade of structure, number and diversities of its representatives; and the relations which the existing members of the class bear to its past condition. Fifteen years ago, the oldest known reptilian remains were those of the so-called "Thuringian Monitor," from the Permian copper-slates of Germany. Five years ago, the batrachian *Apateon*, or *Archegosaurus* of the Bavarian coal-field, represented the known commencement of reptilian existence. In October 1851 the following notice appeared in the *Elgin Courant* for the 10th of that month:—

"*Geological Discovery.*—A fossil has been obtained from the old red sandstone at Spynie, near Elgin, which serves to establish the fact that air-breathing Vertebrata of the order *Sauria* existed during the deposition of the Devonian system of rocks, which hitherto had only been surmised from the discovery of impressions of foot-prints on the surface of the strata. This fossil, or rather impression, was brought to a gentleman in Elgin, who now possesses it, by a quarryman, who with praiseworthy care preserved the fragments, without tampering with the impression to any injurious extent, so that its character is unmistakeable. It presents the figure of a reptile about four inches in length, showing the head containing fragments of conical teeth, part of the neck, the back-bone and ribs, the pelvic bones and hind legs, with part of the tail (the rest of the tail, which seems to have been long, being still unexposed). The appearance of this small specimen is very striking,—the animal matter in its decomposition having stained the matrix to a dark ochre, while the rest of the stone is a pale gray, almost white. No doubt this interesting relic will receive a more scientific description than we can pretend to give, but we cannot resist the impulse to announce the occurrence in this district of an object so well calculated to forward the investigations of geologists."[2]

An accurate drawing of this fossil was transmitted to the writer by its possessor, Mr Patrick Duff of Elgin, together with the newspaper containing his announcement of the discovery; and the writer's opinion, written on the inspection of that drawing in October 1851, was to the effect that it was a true saurian reptile. The fossil itself was subsequently transmitted to London, and submitted to different palæontological authorities. To the present writer was kindly accorded the opportunities of having the requisite drawings made for the illustration of the fossil in his *History of British Fossil Reptiles;* the results of a minute and careful comparison of the impression were briefly given in the *Literary Gazette* of December 20; and the name *Leptopleuron*, significative of its most conspicuous lacertian character, was proposed for it. Other palæontologists regarded the fossil as a batrachian reptile,[3] and Dr Mantell assigned to it the name of *Telerpeton;* but all concurred that it belonged to an air-breathing vertebrate animal. The following is the summary of the grounds on which the writer's conclusions as to the higher affinities of the little Elgin reptile, in its class, were based:—

"*Vertebrate air-breathing Life in the Old Red Sandstone.*

"Our readers may recollect that the geological world was startled by the announcement, in the *Elgin Courant* of October 10th, of the discovery of a fossil reptile in the 'old red' at Spynie, near Elgin. The specimen has been submitted to the examination of Professor Owen, from whom we have received the following notice of its nature and affinities:—

"Royal College of Surgeons, *Dec.* 15, 1851.

"Mr Duff, the proprietor of the very remarkable fossil recently discovered in a sandstone of the Devonian system of rocks at Elgin, transmitted me a drawing of it, with the request that I would undertake its examination; to which having gladly acceded, the specimen itself was brought to me by a friend of Mr Duff's. It is the impression, in two pieces of a gray variety of the old red sandstone, of a long and slender four-footed vertebrate animal, four inches and a half in length, clearly belonging, by the form, proportions, and positions of the scapular and pelvic arches, and their appended limbs, to the reptilian class. The osseous substance has disappeared; the cavities in the sandstone which contained it remain, stained by a deposit of an ochreous tint. The impressions are so well defined as clearly to show that there were twenty-six vertebræ between the skull and sacrum, two sacral vertebræ, and thirteen caudal vertebræ, before the tail disappears by dipping into an unexposed part of the matrix. Impressions of twenty-one pairs of ribs are preserved, all very slender, short where they commence near the head, but rapidly gaining length as they are placed further back. The cervical and anterior ribs are expanded, but not bifurcate, at their vertebral end; all the ribs articulate close to the bodies of the vertebræ. In the crocodilian reptiles the anterior ribs are bifurcate, and the posterior ones, with a simple head, articulate with long diapophyses. The distinctive characters of the batrachian skeleton are the double occipital condyle; ribs wanting, or very short and subequal; a single sacral vertebra, and rib-shaped ilium. The first character cannot be determined, the occipital articulation not being preserved in the fossil. Instead of the second character, the fossil shows ribs of varied length, and most of them much longer than in the salamanders, newts, or any known Batrachian. With regard to the third character, the impression in the matrix clearly shows two sacral vertebræ and a short subquadrate pelvis.

"Both the humerus and the femur show the lacertian sigmoid shape, and near equality of length, which distinguish them alike from the crocodilian and batrachian orders; they are likewise, as in lizards, relatively longer than in the newts and salamanders. Near the imperfect impression of the head may be seen the hollow bases of some large, slightly-compressed, conical teeth, which also tell for the saurian and against the batrachian nature of this ancient reptile. I propose to call it *Leptopleuron lacertinum*.[4] Many particulars of minor import, bearing upon the more immediate affinities of this most rare and interesting fossil, have been noted, and will be given, with the figures, in my *History of British Fossil Reptiles*, for which work Mr Duff has kindly consented to place the

[2] *Elgin Courant*, Oct. 10, 1851.

[3] The following notice of this determination of the fossil will be found in the *Athenæum* of Dec. 13, in the title of a paper to be read at the ensuing meeting of the Geological Society:—"Notice of the occurrence of Fossil Foot-Tracks, and the Remains of a Batrachian Reptile, in the Old Red Sandstone of Morayshire, by Capt. Brickenden and Dr Mantell."

[4] Λεπτός, *slender*, πλευρόν, *rib;* for this compound we have the authority of *Poikilopleuron*, already applied to an extinct genus of Saurians.

Ichnology. specimen at my disposal. In the meanwhile, I beg to offer the above *précis* of the main characters of the fossil.

"RICHARD OWEN."

Admitting the saurian affinities of the *Leptopleuron*, it may have been, like the little *Amblyrhynchus* of the Gallopagos Islands, a lizard of marine habits. As no part of the osseous texture is preserved, and the impressions of the vertebræ are only those of the neural arches, we cannot be assured that the bodies of the vertebræ may not have been unossified, and in the same embryonal stage as in some reptiles, next to be noticed, from the coal formations. It is most probable, however, that the *Leptopleuron* was more nearly allied to the thecodont than to the labyrinthodont Reptilia.

Very recently the remains of a true saurian reptile, protected by pitted bony plates like those of crocodiles, but with a broad coracoid like that of *Cetiosaurus* or *Polyptychodon*, have been discovered in the same formation and locality.[1] The matrix is a fine-grained whitish sandstone, with a cement of carbonate of lime. It belongs, according to Sedgwick and Murchison, to the uppermost beds of the "old red" or Devonian system. As yet, however, no characteristic Devonian or old red fossils of any class have been discovered associated with the foregoing evidences of reptiles, which, according to the determination of strata by characteristic fossils, would belong to the secondary or mezozoic period. In the same sandstone, in the quarry at Cummingstone, near Elgin, a continuous series of thirty-four impressions have been observed by Captain Binkendon, and attributed by him to the foot-prints of a quadruped. The impressions are in pairs, forming two parallel rows, the hind one being one inch in diameter, and larger than the fore one in the proportion of three to four. The stride of the animal, on this hypothesis, must have been about four inches.

There are several circumstances under which impressions made on a part of the earth's surface, soft enough to admit them, may be preserved after the impressing body has perished. When a shell sinks into sand or mud, which in course of time becomes hardened into stone, and when the shell is removed by any solvent that may have filtered through the matrix, its place may become occupied by crystalline or other mineral matter, and the evidence of the shell be thus preserved by a cast, for which the cavity made by the shell has served as a mould. If the shell has sunk with its animal within it, the plastic matrix may enter the dwelling-chamber as far as the retracted soft parts will permit; and as these slowly melt away, their place may become occupied by crystallized deposits of any silicious, calcareous, or other crystallizable matter that may have been held in solution by water percolating the matrix, and such crystalline deposit may receive and retain some colour from the soft parts of which it thus becomes a cast.

Evidences of soft-bodied animals, such as *Actiniæ* and *Medusæ*, and of the excremental droppings of higher animals, have been thus preserved. Fossil remains, as they are called, of soft plants, such as sea-weeds, reeds, calamites, and the like, are usually casts in matrix made naturally after the plant itself has wholly perished.

Even where the impressing force or body has been removed directly or shortly after it has made the pressure, evidence of it may be preserved. The hailstone, the ripple wave, the rain-drop, even the wind that bore it along and drove it slanting on the sand, have been registered in casts of the cavities which they originally made on the soft sea-beach; and the evidence of these and other meteoric actions, so written on imperishable stone, have come down to us from times incalculably remote. Every form of animal life that, writhing, crawling, walking, running, hopping, or leaping, could leave a track, depression, or foot-print, behind it, might thereby leave similar lasting evidence of its existence, and also to some extent of its nature.

Ichnology.

The interpretation of such evidences of ancient life has much exercised the sagacity of naturalists since Dr Duncan, in 1828, first inferred the existence of tortoises at the period of the deposition of certain sandstones in Dumfriesshire, from the impressions left on those sandstones, and the casts afterwards formed in those impressions. The faculty of interpreting has been still more racked by similar evidences of more extraordinary foot-prints, probably of large batrachian reptiles, first noticed in 1834 at Hildberghausen in Saxony, in sandstones of the same geological age as those in Scotland.

The vast number and variety of such impressions, due either to physical or meteoric forces, to dead organic bodies, parts or products, or to the transitory actions of living beings, have at length raised up a distinct branch of palæontological research, to which the term "Ichnology" has been given.

In this class of evidences the impressions called "protichnites"[2] (fig. 64), left upon the "Potsdam sandstones" of the older Silurian age in Canada, are the most ancient; but the foot-prints of birds surpass all others in regard to their number, distinctness, and variety of sorts.

But how, it may be asked, are such foot-prints preserved? A common mode may be witnessed daily on those shores where the tide runs high, and the sea-bottom is well adapted to receive and retain the impressions made upon it at low-water.

Dr Gould of Boston, U.S., first called the attention of naturalists to this interesting operation on the shores of the Bay of Fundy, where the tide is said to rise in some places 70 feet in height. The particles deposited by that immense tidal wave are derived from the destruction of previously existing rocks, and consist of silicious (flinty) and micaceous (talcky) particles, cemented together by calcareous (limy) or argillaceous (clayey) paste, containing salts of soda, especially the muriate (common salt), and coloured with various shades of the oxide of iron, of which the red oxide predominates. The perfection of the surface for receiving and retaining an impression depends much upon the micaceous element. Vast are the numbers of wading and sea birds that course to and fro over the extensive tract of plastic red surface left dry by the far retreat of the tide in the Bay of Fundy. During the period that elapses between one spring tide and the next, the highest part of the tidal deposit is exposed long enough to receive and retain many impressions; even during the hours of hot sunshine, to which, in the summer months, this so-trodden tract is left exposed, the layer last deposited becomes baked hard and dry, and before the returning tidal wave, turbid with the same comminuted materials of a second stratum, has power to break up the preceding one, the impressions left on that stratum have received the deposit. A cast is thus taken of the mould previously made, and the sediment superimposed by each succeeding tide, tends more and more surely to fix it in its place. Then, let ages pass away, and the petrifying influences consolidate the sand layers into a fissile rock: it will split in the way it was formed, and the cleavage will expose the old moulds on one surface and the casts on the other.

Another condition for fixing the impressions on a sandy shore is the following:—When an extensive level tract is

---

[1] They were submitted by Sir R. Murchison to the writer's examination at the meeting of the British Association at Leeds, September 24, 1858: similar fossils had previously been assigned to the class of fishes, by the name *Steganolepis*

[2] See Owen, "Description of the Impressions and Foot-prints of the Protichnites from the Potsdam Sandstone of Canada," *Quarterly Journal of the Geological Society*, 1852, p. 214.

[3] Logan, ibid., p. 2.

left dry by the retreating tide, as at the estuary of the small rivers entering the Bay of Morecombe, on the Lancashire coast, those rivers occasionally overflow the sands at low-water, and deposit in the foot-prints made previous to such overflow the fine mud which sudden heavy rains have brought down from the surrounding hills. Again, those sudden "freshets," as they are locally called, sometimes as quickly subside, and the thin layer of argillaceous mud is left dry on the sand before the returning tide. Such layer of mud readily receives and retains the foot-prints of the many birds that course over the flat expanse; and as the tide returns, it deposits in such foot-prints a layer of the fine sand which the rising waters hold in suspension.

The best-defined foot-prints in the new red sandstone quarries at Stourton, on the Cheshire coast, are found where strata of sandstone are separated by a thin layer of argillaceous stone, which, when exposed, soon breaks up and crumbles away. This layer has, however, received the impressions when it was plastic, and the superincumbent deposit of sandstone retains those impressions in relief upon its under surface. The observations which have just been recorded, of the circumstances that produce an interposition of a thin layer of claystone between thicker beds of sandstone, and which circumstances the writer has witnessed in the Bay of Morecombe, explain the formation and the preservation of the best "ichnites" of the labyrinthodont and other reptiles in the new red sandstone of Stourton.

There is a third condition under which impressions, and casts of impressions, on a sandy beach may be preserved. On a dry windy day clouds of fine sand are drifted along the surface exposed at low-water, are spread lightly over all its little inequalities, and fill up every impression that may have been made on it since it was left bare by the retreating waves. On the return of the tide, the fine sand filling the impressions is moistened, and more wet fine sand is added to it; and a cast is thus fixed in the moulds, to be more and more firmly fixed by each deposition from successive tidal waves.

Thus may be witnessed the actual conditions and the circumstances daily occurring that tend to preserve foot-prints and other impressions made on the sea-shore, and which have operated in past time to similarly preserve the impressions then made on tracts alternately exposed and covered by the tidal wave. The merit of having first discerned the nature and cause of the numerous small hemispheric pits and tubercular casts in relief on the surface of certain sandstone slabs, is due to John Cunningham, Esq., F.G.S., architect, of Liverpool.[1] Since that light was thrown on their nature, they have been recognised under various modifications, as impressions of soft rain, of the big-dropped thunder-shower, of rain driven obliquely by the gale, and making impressions with the side of the cup highest opposite the point whence the wind blew, of frozen rain or hail, &c. Whenever a stratum is proved to be a "sedimentary" one,—*i. e.*, to be due to the precipitation of its constituent particles from water, in which they had been previously suspended,—we have evidence of some expanse of water,—proof, in fact, of the existence of that element, with all its properties of condensation by cold, and expansion and vaporization by heat and exposure. Evaporation makes the raw material of rain. No wonder, then, that impressions of rain-drops should be seen on the oldest sedimentary rocks. Conditions are co-ordinated in meteoric as in organic phenomena; one being given, the rest may be deduced.

The oldest rocks in which rain-drop impressions have been observed are those of the Cambrian age at Longmynd, Wales, described and figured by Mr Salter.[2] Many of the micaceous flags of the same formation are covered with ripple, or current marks. They show borings of worms, and a trace of a trilobite (*Palæopyge*) nearly allied to the *Dikelocephalus*—the oldest known trilobite of America (Lower Silurian or Cambrian at St Croix, Minnesota).

It is in "Potsdam sandstones" of the same geological antiquity that the impressions have been discovered which the writer has interpreted to be those of a large entomostraceous Crustacean, in evidence of which the following sample, applicable to a single species, may be given, in illustration of the ichnologist's mode of work.

Protichnites septem-notatus (fig. 64).

The subject so named consists of a series of well-defined impressions, continued in regular succession along an extent of 4 feet; and traceable, with an inferior degree of definition, along a further extent of upwards of 2 feet.

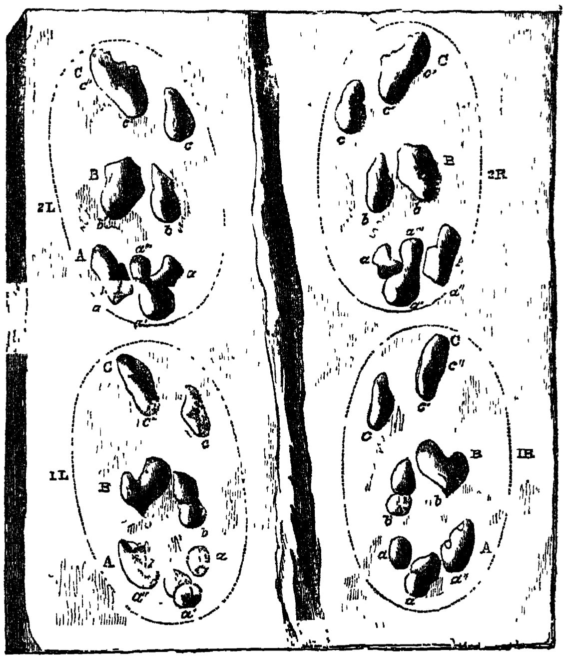

Fig. 64.

Protichnites 7-notatus (Cambrian).

In the extent of 4 feet there are thirty successive groups of foot-prints on each side of a median furrow, which is alternately deep and shallow along pretty regular spaces of about $2\frac{1}{2}$ inches in extent. The number of prints is not the same in each group; where they are best marked, as in fig. 64, 1 L, we see 3 prints in one group, *a*, *a′*, *a″*, 2 prints in the next, *b*, *b′*, and 2 in the third, *c*, *c′*, which is followed by a repetition of the group of 3 prints, *a*, *a′*, *a″*, making the numbers in the three successive groups 3, 2, 2; the three groups of impressions being recognisably repeated in succession along the whole series of tracks on both sides of the median groove.

The principal foot-prints are disposed in pairs, placed with different degrees of obliquity, in each of the three groups, towards the median track; the innermost print in the second, B, and third, C, pairs, which are best marked, being usually rather more than half the size of the outer print, *b′* and *c′*.

The two foot-prints of the same pair are a little further apart from each other, in the three succeeding pairs, as at *a′*, *a″*, *b*, *b′*, *c*, *c′*, especially in the second and third groups of each set; the two forming the pair *a′*, *a″* again approximating in the next series, and the pairs *b*, *b′* and *c*, *c′* diverging in the same direction and degree; and this alternate approximation and divergence is repeated throughout the entire series of the present tracks.

But what strikes the ichnologist, heretofore conversant chiefly with the foot-prints of bipeds or quadrupeds, is the occurrence in

---

[1] Communicated by Dr Buckland to the meeting of the British Association at Newcastle, 1838; and subsequently by Mr Cunningham to the Geol. Soc. (*Proc. of the Geol. Soc.*, vol. iii., 1839, p. 99.)

[2] *Quar. Jour. of the Geol. Soc.*, vol. xii., 1856, p. 250, pl. iv., fig. 4.

Ichnology. the present series of the third impression a, which complicates the most approximated pair A, being placed in front and a little to the inner side of the hindmost impression, a', of that pair. The superadded impression a, is about the same size as the innermost in each pair, the average diameter of that impression being 5 lines.

Taking this view of the impressions, it appears that whilst the innermost in each pair, a', b, c, are of equal size, the outermost, a'', b', c', 1 L, progressively increase in size, from the most approximated to the most divergent of the three pairs; that of the first, a'', being narrow in proportion to its length, that of the second, b', as broad as long, and the outermost, c', c'', of the third pair being oblong, but larger than that in the first pair. In some places where the most approximated pair of impressions, a', a'', are deeply marked, they are complicated by a fourth shallow and very small pit, a''', 2 L, midway between the third, a, and the outermost, a'', of the pair of impressions.

There are no clear or unequivocal marks of toes or nails on any of the impressions which form the lateral pairs or triplets. Their margins are not sharply defined, but are rounded off, and sink gradually to the deepest part, which is a little behind the middle of the depression. There is a slight variation in the form and depth of the answerable impressions, but not such as to prevent their correspondence being readily appreciable through the whole of the extent here described; that is to say, the innermost of each of the three pairs here described as first, A, second, B, and third, C, may be identified with the corresponding innermost impression on the opposite side, and with the same impression of the same pair in the three preceding and the three succeeding pairs.

The impressions selected for fig. 64 clearly demonstrate that the animal, progressing in an undulating course, made at each action of its locomotive members, answering to the single step of the biped and the double step of the quadruped, not fewer than, in *Protichnites 7-notatus*, fourteen impressions, seven on the right and seven on the left; and in *Protichnites* 8-*notatus*, sixteen impressions, eight on the right and eight on the left; these seven and eight impressions respectively being arranged in three groups,—viz., in *Protichnites* 7-*notatus*, three, two, and two, in *Protichnites* 8 *notatus*, three, two, and three,—the groups being re-impressed, in successive series, so similarly and so regularly as to admit of no doubt that they were made by repeated applications of the same impressing instruments, capable of being moved so far in advance as to clear the previous impressions and make a series of new ones at the same distance from them as the sets of impressions in the series are from each other. What then was the nature of these instruments? To this three replies may be given, or hypotheses suggested:—They were made either, first, as in the case of quadrupedal impressions, each by his own limb, which would give seven and eight pairs of limbs to the two species respectively; or, secondly, certain pairs of the limbs were bifurcate, as in some insects and crustaceans, another pair or pairs being trifurcate at their extremities; and each group of impressions was made by a single so subdivided limb, in which case we have evidence of a remarkably broad and short, and, as regards ambulatory legs, hexapod creature; or, thirdly, three pairs of limbs were bifurcate, and the supplementary pits were made by small superadded limbs, as in some crustaceans; or, fourthly, a single broad fin-like member, divided at its impressing border into seven or into eight obtuse points, so arranged as to leave the definite pattern described, must have made the series of three groups by successive applications to the sand.

The latter hypothesis appears to be the least probable,—first, as being most remote from any known analogy; and, secondly, because there are occasional varieties in the groups of foot-prints which would hardly accord with impressions left by one definitely subdivided instrument or member. Thus in the group of impressions marked 1 L in fig. 64, the outer impression, c', is single, but in the preceding set it is divided; whilst the impressions a, a', are confluent in that set, and are separate in 1 L. The same variety occurs in the outer pair, c', c'', in *Protichnites* 8-*notatus*.

Yet, with respect to the hypothesis that each impression was made by its own independent limb, there is much difficulty in conceiving how seven or eight pairs of jointed limbs could be aggregated in so short a space of the sides of one animal. So that the most probable hypothesis is, that the creatures which have left these tracks and impressions on the most ancient of known sea-shores belonged to an articulate and probably crustaceous genus, either with three pairs of limbs employed in locomotion, and severally divided to accord with the number of prints in each of the three groups, or bifurcated merely, the supplementary and usually smaller impressions being made by a small and simple fourth, or fourth and fifth pair of extremities.

The great entomostraceous king-crab (*Limulus*), which has the small anterior pair of limbs near the middle line, and the next four lateral pairs of limbs bifurcate at the free extremity, the last pair of lateral limbs with four lamelliform appendages, and a long and slender hard tail, comes the nearest to my idea of the kind of animal which has left the impressions on the Potsdam sandstone.

Reptilia.

The shape of the pits, so clearly shown in the ice-rubbed slabs, impressed by *Protichnites* 8-*notatus*, accords best with the hard, subobtuse, and subangular terminations of a crustaceous ambulatory limb, such as may be seen in the blunted legs of a large *Palinurus* or *Birgus*; and it is evident that the animal of the Potsdam sandstone moved directly forwards after the manner of the *Macroura* and *Xiphosura*, and not sideways, like the brachyurous Crustaceans.

The appearances in the slab impressed by the *Protichnites multinotatus* favour the view of the median track having been formed by a caudal appendage, rather than by a prominent part of the under surface of the trunk

The imagination is baffled in the attempt to realize the extent of time past since the period when the creatures were in being that moved upon the sandy shores of that most ancient Silurian sea; and we know that, with the exception of the microscopic forms of life, all the actual species of animals came into being at a period geologically very recent in comparison with the Silurian epoch.

The deviations from the living exemplars of animal types usually become greater as we descend into the depths of time past: of this the Archegosaur and Ichthyosaur are instances in the reptilian class. and the *Pterichthys* and *Coccosteus* in that of fishes. If the vertebrate type has undergone such inconceivable modifications during the Secondary and Devonian periods, what may not have been the modifications of the articulate type during a period probably more remote from the secondary period than this is from the present time. In all probability no living form of animal bears such a resemblance to that which the Potsdam foot-prints indicate as to afford an exact illustration of the shape and number of the instruments, and of the mode of locomotion, of the silurian *Protichnites*.

Since the foregoing interpretation of the silurian Ichnites of North America was published, similar impressions have been observed in rocks of the like high antiquity in Scotland, as at Binks, Eskdale, which have received the name of *Protichnites Scoticus*.[1]

CLASS I.—REPTILIA.

Sub-Class 1.—AMPHIBIA.

(*Batrachia.*)

Genus BATRACHOPUS (*Batrachopus primævus*, King.)—In 1844 the scientific world was startled with the announcement by Dr King of Greensburg, Pennsylvania, of the fact that he had discovered unquestionable fossil footmarks of reptiles in the sandstone of the coal measures, in Westmoreland county, near that town. No reptilian footprints or saurian remains had previously been found lower in the series than the *new red sandstone*. Dr King states the impressions to be "near 800 feet beneath the topmost stratum of the coal formation."

Sir C. Lyell, in *Silliman's Journal*, July 1846, describes his visit to Greensburg, where he examined these footmarks, and sustained Dr King's observation and description of them. He considered them to be allied to the labyrinthodont foot-prints which have been referred to the genus *Cheirotherium*. He says,—"They consist, as before stated, of the tracks of a large reptilian quadruped, in a sandstone in the middle of the carboniferous series, a fact full of novelty and interest; for here in Pennsylvania, for the first time, we meet with evidence of the existence of air-breathing quadrupeds capable of roaming in those forests where the Sigillaria, Lepidodendron, Caulopteris, Calamites, ferns, and other plants flourished."

These foot-marks were first observed standing out in relief from the lower surface of slabs of sandstone resting on thin layers of fine unctuous clay, which also exhibited the cracks due to shrinking and drying. Now these cracks, where they traversed the foot-prints, had produced distortion in them, for the mud must have been soft when the animal walked over it and left the impressions; whereas, when it afterwards dried up and shrunk, it would be too hard to receive such indentations, and could only affect them in the way of subsequent dislocation.

[1] Harkness and Salter "On the Lowest Rocks of Eskdale," *Quarterly Journal of the Geological Society*, vol. xii., pp. 238, 243, fig. 2.

No less than twenty-three footsteps, the greater part so arranged as to imply that they were made successively by the same animal, were observed by Dr King in the same quarry.

Everywhere there was a double row of tracks, and in each row they occur in pairs, each pair consisting of a hind and fore foot, and each being at nearly equal distances from the next pair. The hind foot-print is about one-third larger than the fore foot-print: it has five toes, but the front one only four; some of them exhibit a stunted rudiment of the innermost toe or "pollex," which is the undeveloped one. The outermost toe in the hind foot-print is shorter and rather thicker than the rest, and stands out like a thumb on the wrong side of the hand.

With this general resemblance to the foot-prints of Labyrinthodon, from the new red sandstones of Europe, there are well-marked distinctions. In the first place, the right and left series of impressions are wider apart, indicative of a broader-bodied animal. The front print in *Batrachopus* has only four well-developed toes instead of five, as in *Labyrinthodon*; it is also proportionably larger, —the fore foot in *Labyrinthodon* being less than half the size of the hind foot. The distance between the fore and hind print of each pair, and of one such pair from the next on the same side, is nearly the same in *Batrachopus* and *Labyrinthodon*.

Genus SAUROPUS, Rogers.—Very similar foot-prints were discovered and described by Mr Isaac Lea in a formation of red shales, at the base of the coal measures at Pottsville, 78 miles N.E. of Philadelphia. These are of older date than the preceding, inasmuch as a thickness of 1700 feet of strata intervenes between the foot-prints at Greensfield and these older Pottsville impressions.

Professor H. D. Rogers, in 1851, announced his discovery in the same red shales, between the Devonian and carboniferous series, of three species of four-footed animals, which he deems to have been rather saurian than batrachian, seeing that each foot was five-toed; one species, the largest of the three, presented a diameter for each foot-print of about two inches, and showed the fore and hind feet to be nearly equal in dimensions. It exhibits a length of stride of about 9 inches, and a breadth between the right and left footsteps of nearly 4 inches. The impressions of the hind feet are but little in the rear of the fore feet. With these foot-marks were associated shrinkage cracks, such as are caused by the sun's heat upon mud, and rain-drop pittings, with the signs of the trickling of water on a wet beach,—all confirming the conclusions derived from the foot-prints, that the quadrupeds belonged to air-breathers, and not to a class of animals living in and breathing water.

ORDER I.—GANOCEPHALA.

Genus APATEON, Von M.; ARCHEGOSAURUS,[1] Goldf.—Certain fossils, discovered in the sphærosideritic clay-slate forming the upper member of the Bavarian coal measures; and also in splitting spheroidal concretions from the coal-field of Saarsbruck, near Treves, had been referred to the class of fishes (*Pygopterus Lucius*, Agassiz). But a specimen from the Brandschiefer of Munster-Appel presented characters which were recognised by Dr Gergens to be those of a salamandroid reptile.[2] Dr Gergens placed his "salamander" in the hands of H. von Meyer for description, who communicated the result of his examination in a later number of the under-cited journal.[3] In this notice the author states that the salamander affinities of the fossil in question, for which he proposes the name of *Apateon pedestris*, "are by no means demonstrated."[4] "Its head might be that of a fish as well as that of a lizard, or of a Batrachian." "There is no trace of bones or limbs." M. von Meyer concludes by stating that, in order to test the hypothesis of the *Apateon* being a fossil fish, he has sent to Agassiz a drawing with a description of it.

Three years later, better preserved and more instructive specimens of the problematical fossil were obtained by Professor von Dechen from the Bavarian coal-fields, and were submitted to the examination of Professor Goldfuss of Bonn: he published a quarto Memoir on them, with good figures, referring them to a saurian genus which he calls *Archegosaurus*, or primæval lizard, deeming it to be a transitional type between the fish-like Batrachia and the lizards and crocodiles.[5]

The estimable author, on the occasion of publishing the above Memoir, transmitted to the writer excellent casts of the originals therein described and figured. These casts were presented to the museum of the Royal College of Surgeons, and were described by him in his Catalogue of the Fossil Reptiles, 4to, 1850. The conclusions which the writer formed thereupon as to the position and affinities of the *Archegosaurus* in the reptilian class were communicated in the *Quarterly Journal of the Geological Society*, vol. iv., 1848. One of the specimens appeared to present evidence of persistent branchial arches. The osseous structure of the skull, especially of the orbits, through the completed zygomatic arches, indicated an affinity to the Labyrinthodonts; but the vertebræ and numerous very short

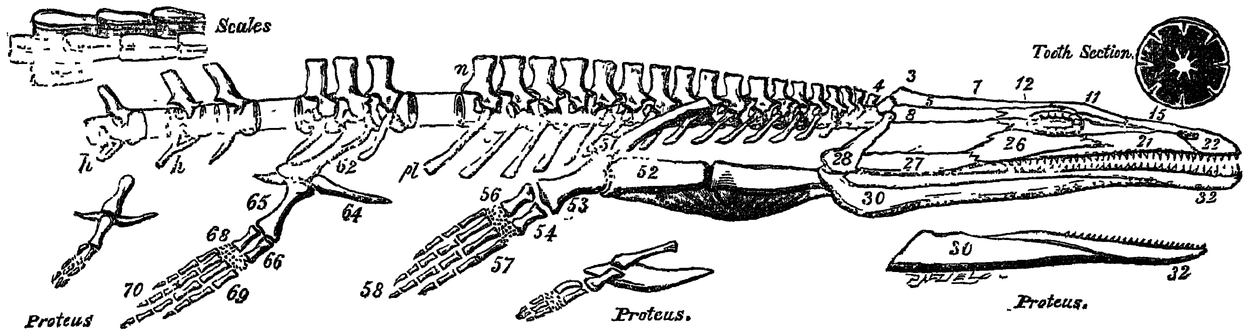

Fig. 65.

Apateon or *Archegosaurus* (Carboniferous).

ribs, with the indications of stunted swimming limbs, impressed the writer with the conviction of the near alliance of the *Archegosaurus* with the *Proteus* and other perennibranchiate reptiles.

This conclusion of the affinity of *Archegosaurus* to existing types of the reptilian class is confirmed by subsequently-discovered specimens, some of which have been acquired by the British Museum, others have been described and figured by H. von Meyer in his *Palæontographica* (Bd. vi, 2to Lief. 1857); more especially by his discovery of the embryonal condition of the vertebral column,—*i. e.*, of the persistence of the notochord, and the restriction of ossification to the arches and peripheral vertebral elements. In this structure the old carboniferous reptile resembled the existing *Lepidosiren*,

Reptilia.

and affords further ground for regarding that remarkable existing animal as one which obliterates the line of demarcation between the fishes and the reptiles.

Coincident with this non-ossified state of the basis of the vertebral bodies of the trunk (fig. 65, *ε*), is the absence of the ossified occipital condyles which characterizes the skull in better developed *Batrachia*. The fore part of the notochord has extended into the basi-sphenoid region, and its capsule has connected it by ligament to the broad flat ossifications of expansions of the same capsule, forming the basi-occipital or basi-sphenoid plate. In fig 63 are represented the chief modifications of the vertebræ, as shown in the neck, thorax, abdomen, sacrum, and tail. The vertebræ of the trunk in the fully-developed full-sized animal present the following stage of ossification:—

The neurapophyses (fig. 65, *n*) coalesce at top to form the arch from the summit of which was developed a compressed, sub-quadrate, moderately high spine, with the truncate or slightly convex summit expanded in the fore and aft direction so as to touch the contiguous spines in the back; the spines are distinct in the tail. The sides of the base of the neural arch are thickened and extended outwards into diapophyses, having a convex articular surface for the attachment of the rib, *pl*; the fore-part is slightly produced at each angle into a zygapophysis looking upwards and a little forward; the hinder part was much produced backwards, supporting two thirds of the neural spine, and each angle developed into a zygapophysis, with a surface of opposite aspects to the anterior one. In the capsule of the notochord three bony plates were developed, one on the ventral surface, and one on each side, at or near the back part of the diapophysis. These bony plates may be termed cortical parts of the centrum, in the same sense in which that term is applied to the element which is called "body of the atlas" in man and Mammalia, and "sub-vertebral wedge-bone" at the fore part of the neck in Enaliosauria.

As such neural or inferior cortical elements co-exist with seemingly complete centrums in the *Ichthyosaurus*, thus affording ground for deeming them essentially distinct from a true centrum, the term "hypopophysis" has been proposed for such independent inferior ossifications in and from the notochordal capsule; and by that term may be signified the sub-notochordal plates in *Archegosaurus*, which co-exist with proper hæmapophyses (*h*) in the tail. In the trunk they are flat, subquadrate, oblong bodies, with the angles rounded off; in the tail they bend upwards by the extension of the ossification from the under to the side parts of the notochordal capsule; sometimes touching the lateral cortical plates. These serve to strengthen the notochord and support the intervertebral nerve in its outward passage. The ribs (*pl*) are short, almost straight, expanded and flattened at the ends, round and slender at the middle. They are developed throughout the trunk and along part of the tail, co-existing there with the hæmal arches, as in the Menopome.[1] The hæmal arches (*h*), which are at first open at their base, become closed by extension of ossification inwards from each produced angle, converting the notch into a foramen. This forms a wide oval, the apex being produced into a long spine; but towards the end of the tail the spine becomes shortened, and the hæmal arch reduced to a mere flattened ring.

The size of the canal for the protection of the caudal blood-vessels indicates the powerful muscular actions of that part, as the produced spines from both neural and hæmal arches bespeak the provision made for muscular attachments, and the vertical development of the caudal swimming organ.

The skull of the *Archegosaurus* appears to have retained much of its primary cartilage internally, and ossification to have been chiefly active at the surface; where, as in the combined dermo-neural ossifications of the skull in the sturgeons and salamandroid fishes,—*e.g. Polypterus, Amia, Lepidosteus*, these ossifications have started from centres more numerous than those of the true vertebral system in the skull of saurian reptiles This gives the character of the present extinct order of *Batrachia*.

The skull is much flattened or depressed, triangular, with rounded angles, and the front one more or less produced according to the species; and in some species according to the age of the individual. The base is concave; the sides nearly straight, or slightly concave. The basi-occipital appears to have retained its primordial soft, unossified state.

Of the ex-occipitals, in a distinctly ossified state, no clear view has yet been had. The super-occipital (fig. 65, 4) is represented, as in the salamandroid fishes, by a pair of flat bones, more probably developed in the epicranial membrane and integument than in the cartilaginous protocranium.

The pair of bones external to these, and forming the prominent angles of the occipital region, represent the "par-occipitals."

The lower peripheral surface of the basi-sphenoidal cartilage is ossified with a concave border towards the notochord behind, to the capsule of which it seems to have been attached. The ali-sphenoids were doubtless cartilaginous, and the protocranium there unaltered, as it was apparently in the ex-occipital region.

The peripheral ossifications above representing the "parietal" (7), form a pair of oblong flat bones, with the "foramen parietal" in the mid-suture. External to these, and wedged between them, the super- and par-occipitals, are the pair of bones answering to the "mastoids" (8). They give attachment externally and below to the tympanic (28), and to a subsidiary bony plate, holding the position of that development of the mastoid which roofs over the temporal fossa in the *Chelonia*. it may be termed "supra-squamosal" (the bone between 8 and 27 in fig. 65). The frontal bones (11), divided by a mid-suture, like the parietals, increase in length, and are continued far in advance of the orbits. The bone (12) which occupies the position of the post-frontal in *Chelonia* is ossified from two centres, one articulating with the mastoid (8), the other, which is external to it, with the supra-squamosal. This other bone may be termed the "post-orbital," as proposed by Von Meyer The post-frontal extends forward above the orbit to meet the pre-frontal, separating the frontal (11) from the orbit, as in the sturgeon (*Acipenser*), *Polypterus*, and *Lepidosteus*, and also in some *Chelones*.

The pre-frontal extends far forward, terminating in a point between the nasal (15) and lacrymal. The nasals (15), divided by the median suture, extend to the external nostrils, their prolongation varying with the species and age of the individual.

Thus far the ossification of the superficies of the skull of *Archegosaurus* closely conforms to that of the salamandroid ganoid fishes above cited; and the homologous bones are determinable without doubt.

The lacrymal bone obviously answers to the front large suborbital scale-bone in fishes; its large size and forward extension in *Archegosaurus* is a mark of that affinity.

The upper jaw consists of pre-maxillary (22), maxillary (21), and palatine bones. The pre-maxillaries are divided by a median suture, as in *Lepidosteus* and *Crocodilus*, and are short bones, the breadth exceeding the length in *A. latirostris*, and also in the young of *A. Decheni*; but in the old animal opposite proportions prevail. In *A. Decheni* each pre-maxillary contains eight teeth; in *A. latirostris* not less than eleven. The maxillary (21) which extends from the pre-maxillary to beneath and beyond the orbit, presents a great length, varied according to species and age; it is of small vertical extent, and terminates in a point, which reaches the tympanic. Anteriorly it unites with the pre-maxillary, and enters into the formation of the back boundary of the nostril; mesially it unites above with the lacrymal and suborbital, and below forms the outer boundary of the choanal aperture, joining the vomer anteriorly, and the palatine posteriorly. The palatine is a long narrow bone, rather expanded at both extremities; it forms anteriorly the hinder border of the choanal aperture, and mesially throughout a great part of its extent the outer boundary of the great palatal vacuity. It supports a row of teeth, of which one or two at the fore part are of large size.

Between the orbit and the maxillary extends an oblong flat bone (26), forming the lower or outer border of the orbit, uniting with the pre-frontal and lacrymal anteriorly, with the maxillary below, and with the tympanic (9) and another bone behind. In this position, and in its connections, it agrees with the malar of the crocodile, and also with the suborbital bone or bones of fishes. The latter are unequivocally muco-dermal bones, and may not be the homologues of the endo-skeletal malar bone of saurians, birds, and mammals.

To which of the bones, therefore, suborbital or malar, the one in question of the *Archegosaurus* answers, may be doubtful. The writer inclines to view it as a dermal ossification, and to conclude that, as in the higher *Batrachia*, the true malar and the zygomatic arch are not developed. Admitting the doubt on this point, the bone (26) may be termed the "suborbital."

With regard to the next bone (27), the same question, whether it answers to the squamosal in the crocodile, or whether it is a dermal ossification, applies.

If a homology with a determinate endo-skeletal bone in the crocodile and higher vertebrates were to be predicated, it would be as the "squamosal." Essentially it indicates the tendency to excessive dermal ossification of the skull, like that which extends into the superficial temporal fascia from the squamosal and mastoid in the *Chelonia*; this separate ossification in *Archegosaurus* roofs over the temporal fossa. It appears like a posterior repetition of the supernumerary surface-bones called post-orbital and paramastoid, and, like them, corresponds in position with the posterior suborbital scale-bones in *Amia* and *Lepidosteus*.

The hinder angles of the skull are formed by the tympanic; in

[1] "Principal Forms of the Skeleton," Orr's *Circle of the Sciences*, p. 187, fig. 11.

young individuals the tympanic does not extend backward beyond the par-occipital, but as age advances it projects further backward. It appears to abut internally against the pterygoid.

The two rami of the mandible were loosely united at a short symphysis, not exceeding the breadth or depth of the jaw at that point; the depth gradually augments to near the articular end, but never exceeds a sixth, and is usually only an eighth of the length of the jaw, no definite coronoid process being developed, the upper and lower borders are nearly straight as far as the deepest part. The lower border behind this part rises rather abruptly to an angle, which is just below the articular pit. The angular element (30) presents a convexity answering to the point of ossification whence some faint ridges radiate upon its outer surface. The dentary (32), if it does not form the articular surface, begins very near it, and each ramus appears to be composed of these two bones. The dentary develops the coronoid rising. Neither articular nor splenial element has been clearly demonstrated. If an articular element has existed, it has been very small.

From fishes the lower jaw of *Archegosaurus* differs in the great length or forward extension of the angular piece (30); but it resembles the piscine type in the simplicity of its composition. The angular piece is, however, longer in the Ganoids,—*e.g.*, *Amia*, *Polypterus*, *Lepidosteus*,—than in other fishes; and in *Lepidosiren* its proportions are almost those of the *Archegosaurus*. It offers similar proportions to those in *Archegosaurus*, in the mandible of the *Axolotl* and *Proteus* (fig. 65)

The teeth have the simple conical pointed shape. They are implanted in the premaxillary, maxillary, mandibular, and vomerine bone, and in a single row in each.

In the short premaxillaries there are from 8 (*A. Decheni*) to 12 (*A. latirostri*); they are rather larger than the maxillary teeth. These follow in an unbroken series to beneath and beyond the orbit, and are about 30 in number; but their interspaces are such as would lodge double that number in the same extent of alveolar border.

The vomerine teeth are in a single row, parallel with and near to the maxillary row; one or two behind the choane are much larger than the rest, which resemble the maxillary teeth in size. The mandibular teeth extend backward to the coronoid rising, and decrease in size, the front ones being the largest.

Each tooth is implanted by a simple base in a shallow cup-shaped socket, with a slightly raised border, to which the circumference of the tooth becomes anchylosed. The tooth is loosened by absorption and shed to make way for a successor. These are developed on the inner, hind, and fore part of the base of the old tooth.

The teeth are usually shed alternately. They consist of osteodentine, dentine, and cement. The first substance occupies the centre; the last covers the superficies of the tooth, but is introduced into its substance by many concentric folds, extending along the basal half. These folds are indicated by fine longitudinal, straight striæ along that half of the crown. The section of the tooth at that part (see fig. 65, tooth-section) gives the same structure which is shown by a like section of a tooth of the *Lepidosteus oxyurus*.[1]

The same principle of dental composition is exemplified in the teeth of most of the ganoid fishes of the carboniferous and Devonian systems, and is carried out to a great and beautiful degree of complication in the "old red" Dendrodonts.

The repetition of the same principle of dental structure in one of the earliest genera of *Reptilia*, associated with the defect of ossification of the endo-skeleton and the excess of ossification in the exo-skeleton of the head and nape, decisively illustrate the true affinities and low position in the reptilian class of the so-called *Archegosauri*.

Resting upon and protected by the throat-plate in the middle line, there is a longish slender bone, which must belong to the median series of the hyoid system, either basi- or uro-hyal; it is most probably homologous with the uro-hyal of *Amphiuma* and other Perennibranchiates.

That two pairs of longish slender bones projected outward and backward from the median series, is shown by more than one specimen of *Archegosaurus* (vol. xii., fig. 10). The anterior pair is the longest; these are situated as if they had been attached, one to each side of the broad "throat-plate," which may have represented a basi-hyal. The anterior pair are homologous with the corresponding longer pair of appendages to the broad basi-hyal of *Amphiuma*, and are cerato-hyals. The shorter posterior pair answer to the branchi-hyals in *Amphiuma* and other Perennibranchs. There is no such pair in the hyoidean arch of any known Saurian.

Just external to the ends of the above lateral elements of the hyoid apparatus feeble traces of arched series of bony nuclei were detected by Goldfuss, and interpreted by him as remains of partially ossified branchial arches In this determination the writer agrees with Goldfuss. In all those specimens possessing them they present the outline of two or three arches in dots, or slightly curved series of dots or points. In the small relative size of these indications of branchial arches, the *Archegosaurus* agrees with the *Amphiuma*.

No doubt, in the fully-grown *Archegosaurus*, the lungs would be equal to the performance of the required amount of respiration, but the retention of such traces of the embryonal water-breathing system in the adult leads to the inference that the animal must have affected a watery medium of existence for as great a proportion of its time as is observed to be the case in the existing perennibranchiate reptiles; in which, notwithstanding the degree of development of the lungs, the great proportion of the respiratory functions seems to be performed by the gills.

The additional marks of affinity to fishes which the *Archegosaurus* presents in its persistent notochord, its cartilaginous basi-occipital, its dermal ossifications on the head, and its minute body-scales (fig. 65, scales), remove it further from the saurian reptiles, and exhibit it more strongly in the light of an osculant form between the Batrachians and the Ganoids

Throat-Plates.—The under surface of the body between the head and trunk, is defended by broad bony plates, three in number. One is median and symmetrical, of an elongate lozenge shape, with the angles rounded off, slightly convex externally, a little produced along the middle of the anterior half into something like a low *quasi*-keel. The outer surface is sculptured by radiating furrows, except at so much of the marginal part as is overlapped by the lateral pieces, and by the scapular arch. The lateral throat-plates are attached to the anterior half of the sides of the median one, are shaped like beetles' elytra, and converge forwards. Their centre of ossification is towards their outer and back part, from which the external ridges and grooves radiate towards the inner border

Von Meyer[2] compares these dermal shields to the ento- and episternal elements of the plastron of Chelonia; their truer homology seems to the writer to be with the median and lateral large throat-plates or scales of *Megalichthys* and *Sudis gigas*. The entosternal element is the only endo-skeletal piece uncombined with a dermal ossification in most Chelonia. The epi-sternal, like the hyo- and hypo-sternals, appear to be abdominal ribs, with superadded dermal ossifications in *Chelonia*.

The scapulæ (51) are instructively exhibited in the very young specimen of the *Archegosaurus* figured in t. xiv., fig. 4, of Von Meyer's treatise. The coracoids being doubtless wholly cartilaginous at that stage, are not discernible in the specimen referred to. The upper slender end of the scapula is opposite the side of the vertebral column, about the fifth neurapophysis from the head, and it curves gently downward and forward, expanding at its humeral end.

This expansion is more sudden in the fully-developed animal, giving the bone the shape of a rudder, and the direction of the scapula is changed. At least in the specimens (the great majority) in which the skeleton is seen from above, the slender dorsal end of the scapula is seen overlying, or near the hinder border of, the lateral throat-plate, and it extends outward and backward to its expanded humeral end.

The coracoids (52) are a pair of flat reniform plates, with the convex border turned forward, the concave one backward, they seem to have overlapped the smooth margins of the posterior half of the median throat-plate. It is most probable that, as in *Amphiuma*, a portion of the broad coracoid remained in the cartilaginous state, and that the full reniform plate answers to the ossified part of that coracoid which it resembles in shape and relative position

The position of the slender scapulæ, styliform and rib-like, as in the Perennibranchiates, is instructively shown in t. xviii., figs. 1 and 2, of M. von Meyer's treatise. The coracoids, as in *Amphiuma*, form the chief part of the articular cavity for the humerus.

The perennibranchiate affinities of *Archegosaurus* are shown as clearly by the scapular as by the hyoidean arch. The fore-limb does not exceed half the length of the head The humerus (53) is a short thick bone, slightly constricted at the middle, expanded and rounded at both ends, the proximal one being the largest. For some time the bone is hollow and open at each end; when ossification finally closes the terminal apertures, it shows that the ends were connected to the coracoid and to the fore arm by interposed ligamentous matter,—not, as in true Saurians, by a synovial joint. Of the two bones of the fore arm the ulna is a little longer and larger than the radius (54). Both bones present the simplest primitive form, gently constricted in the middle, with the proximal

1 Wyman, *American Journal of the Natural Sciences*, Oct. 1843.

2 "Die kehlbrust platten konnte man der unpaarigen Platte und dem ersten Platten-paar im Bauchpanzer der Schildkroter vergleichen." (*Op. cit.*, p. 100.)

Reptilia.

ends a little concave, the distal ones a little convex. The space between the antibrachium and the metacarpus plainly bespeaks the mass of cartilage representing, as in *Amphiuma*, the carpal segment (56) in *Archegosaurus*. No trace of a carpal bone is found save in the largest and oldest examples, in which five or six small roundish ossicles are aggregated near the ulnar side of the carpus. Four digits are present; and considering the pollex to be, as usual, wanting, the second digit, answering to the medius of pentadactyle feet, is the largest, and includes at least four phalanges (58); these, with the metacarpals (57), are long, slender, terminally expanded, and truncate. They obviously supported a longish, narrow, pointed paddle. The outermost or little finger was the shortest, and has the shortest metacarpal and first phalanx.

It is true that in *Mystriosaurus* the fore limbs are relatively as short as in *Archegosaurus*; and the oolitic crocodile recalls the arrest of development of the same limbs in the marsupial Potoroos; but in *Archegosaurus*, not only is the small size of the fore limbs, but also their type of structure, especially that of their scapular arch, closely in accordance with that in the *Perennibranchiata*, as shown in the tridactyle fore limb of the *Proteus anguinus*, of which a figure is added to that of the *Archegosaurus* in fig. 65.

The ilium (62), like the scapula, is expanded at its articular or femoral end. It is less long and slender; one border is straight, the other concave, by the expansion toward that border of the femoral end. Two shorter bones on each side complete the pelvis below. One is of a simple form, straight, thicker in proportion to its length than in the ilium: it may be ischium.

The other bone is shown, with its fellow, in t. xiii., fig. 6, and xviii., figs. 8 and 9, of Von Meyer's treatise. That author compares the pair of bones to the *Aptychus* in shape; they may be the pubic bones. On this hypothesis, they are restored to their true position at 64 (pubis) in fig. 65. The femur (65) is slightly expanded, and truncate at both ends; it is not longer than the ilium. The tibia (66) and fibula are separate bones, like those of the fore arm; the margins, which are turned toward each other, are most concave. They are rather more than half the length of the femur.

The foot-bones are separated by a fibro-cartilaginous tarsal mass (68) from those of the leg. The form of the phalanges, expanded and truncate at both ends, bespeaks their simple ligamentous joints, and that they supported, like the fore limb, a fin or limb adapted simply for swimming. The argument for the saurian affinities of *Archegosaurus*, based by V. Meyer on the short fore-limbs of *Mystriosaurus*, already invalidated by the difference of structure, is controverted by the fact, that the hind limbs of *Archegosaurus*, like those of the Perennibranchs, are not only as simple in structure, but also as short, as the fore limbs.

In 1852 Sir Charles Lyell and Mr Dawson, in the course of their investigations of the coal strata of Nova Scotia, remarkable for the erect fossil trees in certain parts, discovered in the hollow of the trunk of one of these trees (*Sigillaria*, 2 feet in diameter), which was wholly converted into coal, some small bones, which Professor Wyman of Boston surmised to have belonged to a batrachian reptile. By the professor's advice they were brought to England and submitted to the writer, who has described and figured them[1] as batrachian, under the name *Dendrerpeton Acadianum*, and with close affinities, from the plicated structure of the teeth, the sculpturing of some broad cranial plates, and the structure and proportions of certain limb-bones, to the genus *Apateon* or *Archegosaurus*.

Genus Raniceps.—In about the centre of the great carboniferous basin of Ohio, United States, at the mouth of the "yellow creek," is a seam of coal 8 feet in thickness, the lower four inches of which is "cannel coal." In this has been found the skull, part of the vertebral column, scapular arch, and fore limbs of a reptile referred by Professor Wyman[2] to the batrachian sub-class, under the name of *Raniceps*. Two closely-allied fossils, also referred to *Batrachia*, have been found in the same formation and locality.

Order II.—Labrinthodontia.

Genus Baphetes, Ow.

Sp. *Baphetes planiceps*.—In January 1854 the writer communicated to the Geological Society of London a description of part of a fossil cranium of an animal, from the Pictou coal, Nova Scotia, measuring 7 inches across the orbit. From the characters then specified, the fossil was determined to be the fore part of the skull of a sauroid Batrachian of the extinct family of the Labyrinthodonts. It agreed with them in the number, size, and disposition of the teeth; in the proportions and mode of connection of the premaxillaries, maxillaries, nasals, prefrontals and frontals; and in the resultant peculiarly broad and depressed character of the skull. The traces of the nostrils were less definite and satisfactory than the remains of the orbits; but the latter were decisive against a piscine nature. The fossil also presents the same well-marked external sculpturing as in the Labyrinthodonts; and amongst the genera that have been established in that family, the form of the end of the muzzle, or upper jaw, in the Pictou coal specimen, best accorded with that in the *Capitosaurus* and *Metopias* of Von Meyer and Burmeister. But the orbits had been evidently larger and of a different form than in the reptiles so called; and, for the convenience of distinction and reference, the writer proposed to name the fossil *Baphetes planiceps* (βάπτω, *I dip* or *dive*), in reference to the depth of its position and the shape of its head.

Being thus introduced at the carboniferous period to the labyrinthodont order, which attained its full development in the triassic period, we shall proceed to notice the more decisive evidences and typical illustrations of that extinct order of *Batrachia*.

The name of this sub-class is from the Greek word *batrachos*, signifying a frog; and it is represented in the present animal-population of England by a few diminutive species of frogs, toads, and newts, or water-salamanders. But, at the period of the deposition of the new red sandstone, in the present counties of Warwick and Cheshire, the shores of the ancient sea, which were then formed by that sandy deposit, were trodden by reptiles having the essential bony characters of the *Batrachia*, but combining these with other bony characters of crocodiles, lizards, and ganoid fishes; and exhibiting all under a bulk which, as made manifest by the fossils and foot-prints, rivalled that of the largest crocodiles of the present day. The form of the largest Labyrinthodonts, if we may judge by the great breadth and flatness of the skull, must, however, have more resembled that of the toad or land-salamander.

The Batrachians have no fixed type of external form like the higher orders of reptiles, but some, as the broad and flat-bodied toads and frogs, most resemble the Chelonians, especially the soft-skinned mud-tortoises (*Trionyx*); other Batrachians, as the *Cæcilia*, resemble Ophidians; a third group, as the newts and salamanders, represent the Lacertians; and among the perennibranchiate reptiles there are species (*Siren*) which combine with external gills the mutilated condition of the apodal fishes.

Thus it will be perceived that, even if the entire skeleton of one of the new red sandstone Batrachians had been obtained, there is no fixed or characteristic general outward form in the batrachian order whereby its affinity to that group could have been determined. The common characters by which the Batrachians, so diversified in other respects, are naturally associated into one group or sub-class of reptiles, besides being taken from the condition of the circulating and generative systems, and other perishable parts, are, however, fortunately as strongly manifested in modifications of the skeleton, and principally in the skull. This is joined to the atlas by the medium of two tubercles, developed exclusively from the exoccipitals; the bony palate is formed chiefly by two broad and flat bones, called "vomerine" by Cuvier, and generally supporting teeth. It is only in the Batrachians among reptiles that examples are found of two or more rows of teeth on the same bone, especially on the lower jaw (*Cœciliæ*, *Sirenes*). With regard to vertebral characters, no such absolute batrachian modifications can be adduced as those above cited from the anatomy of the cranium. Some Batrachians, as is well known, have the vertebræ united by ball-and-socket joints, as in most recent reptiles; others by biconcave joints, as in a few recent and most extinct Saurians. Some species have ribs, others want those appendages; the possession of ribs, therefore, even if longer than those of the *Cœciliæ*, by a fossil reptile combining all the essential batrachian characters of the skull, would not be sufficient ground for pronouncing such reptile to be a Saurian.

[1] *Quarterly Journal of the Geological Society*, vol. ix., 1853.

[2] *American Journal of Science and Arts*, March 1857.

Much less could its saurian nature be pronounced from the circumstance of its possessing large conical striated teeth,—as the ordinary characters of size, form, number, and even presence or absence of teeth, varies much in existing Batrachians, the location of teeth on the vomerine bones being the only dental character in which they differ from all other orders of reptiles.

The writer's first acquaintance with the remarkable fossils under consideration was founded on the examination, in 1840, of portions of teeth from the new red sandstone of Coton End quarry, Warwickshire. The external characters of these teeth corresponded with those which had previously been discovered by Professor Jaeger in the German Keuper formation in Wirtemberg, and on which the genus *Mastodonsaurus* had been founded (fig. 66).

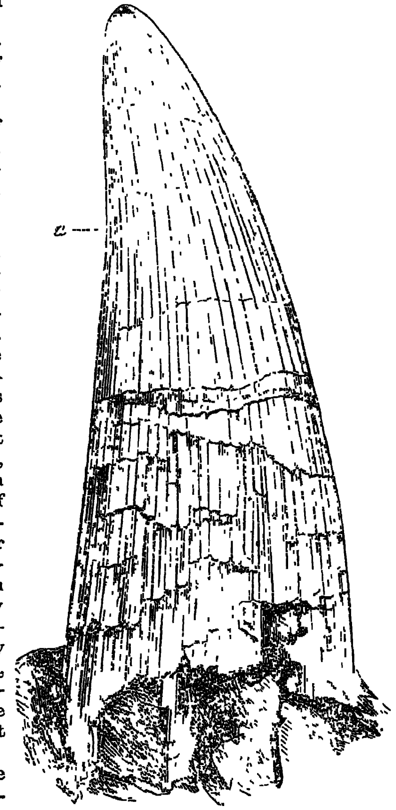

Fig. 66.
Canine tooth of the *Labyrinthodon Jagaeri* (nat. size).

The results of a microscopic examination of the teeth of the *Mastodonsaurus* from the German Keuper, and of those from the new red sandstone of Warwickshire, have been detailed in the art. ODONTOLOGY (vol. xvi., p. 412). They proved that the teeth from both localities possessed in common a very remarkable and complicated structure (fig. 67), to the principle of which,—viz., the convergence of numerous inflected folds of the external layer of cement towards the pulp cavity, a very slight approach was made in the fang of the tooth of the *Ichthyosaurus*, and that a closer approximation to the labyrinthic structure in question was made by the teeth of several species of fishes, and by those of *Archegosaurus*, while the teeth of existing Batrachians were simple like those of most Saurians.

Thus, inasmuch as the extinct animals in question manifested in the intimate structure of their teeth an affinity to fishes, it might be expected that, if they actually belonged to the class of reptiles, the rest of their structure would manifest the characters of the lowest order,—viz., the *Batrachia*, the existing members of which pass, though not by the dental character alluded to, yet by so many other remarkable degradations of structure, towards fishes. Now it has happened that, in the same formation in Wirtemberg from which the labyrinthic teeth of the so-called *Mastodonsaurus* had been derived, a fragment of the posterior portion of the skull has been obtained, showing the development of a separate condyle on each ex-occipital bone; whence Professor Jaeger, recognising the identity of this structure with the batrachian character above mentioned, founded upon the fossil a new genus of *Batrachia* which he called "*Salamandroides giganteus*." Subsequent discoveries, however, satisfied the professor that the bi-condylous fragment of skull, representing the genus *Salamandroides*, belonged to the same reptile as the teeth on which he had founded the genus *Mastodonsaurus*. The following fossils, from the new red sandstone of Warwickshire, gave additional proof of the batrachian nature of the genus to which those fossils belong, with the establishment of five distinct species, one of which is most probably identical with the *Mastodonsaurus salamandroides* of Professor Jaeger. In reference to the generic denomination *Mastodonsaurus*, it unavoidably recalls the idea of the mammalian genus *Mastodon*, or else a mammilloid form of tooth, whereas all the teeth of the reptile so called are originally, and most of them are permanently, of a cuspidate and not of a mammilloid form; secondly, because the second element of the word, *saurus*, indicates the genus to belong to the saurian and not to the batrachian order of reptiles. For these reasons, the writer has proposed to designate the genus in question *Labyrinthodon*, in allusion to the peculiar and characteristic structure of the teeth (fig. 67).

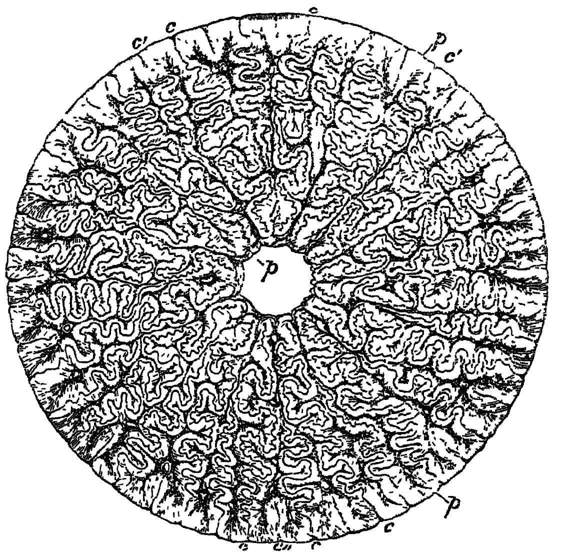

Fig. 67.
Transverse section of a tooth of the *Labyrinthodon* (magn.)

The specimens from British localities are referable to five species, —viz., 1. *Labyrinthodon salamandroides*; 2. *L. leptognathus*; 3. *L. pachygnathus*; 4. *L. ventricosus*; and 5. *L. scutulatus*; and we shall here briefly notice the characters exhibited by the bones assignable to the second, third, and fifth species.

Labyrinthodon leptognathus.—The remains of this species consist of fragments of the upper and lower jaws, two vertebræ, and a sternum. They were found in the new red sandstone quarries at Coton End, near Warwick.

A dorsal vertebra from Coton End presents further evidence of the batrachian nature of the *Labyrinthodon*. It has concave articular cavities at the extremities of the body,—a condition now known among existing reptiles only in the Geckos, and in the lower or perennibranchiate division of Batrachians. It is a common structure in extinct Saurians, but the depth of the vertebral articular cavities in the *Labyrinthodon* exceeds that in the amphicelian Crocodilians and in most Plesiosaurs. The body of the vertebra is elongate and sub-compressed, with a smooth but not regularly curved lateral surface, terminating below in a slightly-produced, longitudinal, median ridge; and it exhibits the same exceptional condition in the reptilian class as do the vertebræ of existing Batrachians, in having the superior arch or neurapophysis anchylosed with the centrum. From each side of the base of the neural arch a thick and strong transverse process extends obliquely outwards and upwards.

A symmetrical bone, resembling the episternum of the *Ichthyosaurus* was associated with the preceding remains. It consists of a stem or middle, which gradually thickens to the upper end, where cross pieces are given off at right angles to the stem, and support on each a pretty deep and wide groove indicating strongly the presence of clavicles, and thus pointing out another distinction from crocodiles, in which clavicles are wanting. Most Batrachians possess these bones.

The modifications of the jaws, and more especially those of the bony palate of the *Labyrinthodon leptognathus*, prove the fossil to have been essentially Batrachian, but with affinities to the higher Sauria, leading, in the form of skull and the sculpturing of the cranial bones, to the crocodilian group, in the collocation of the larger fangs at the anterior extremities of the jaws to the *Plesiosaurus*, and in one part of the dental structure, in the form of the episternum, and the bi-concave vertebræ, to the *Ichthyosaurus*. Another marked peculiarity in this fossil is the anchylosis of the base of the teeth to distinct and shallow sockets, by which it is made to resemble the Sphyræna and certain other fishes. From the absence of any trace of excavation at the inner side of the base of the functional teeth, or of alveoli of reserve for the successional teeth, it may be concluded that the teeth were reproduced, as in the lower Batrachians and in many fishes, in the soft mucous membrane which covered the alveolar margin, and that they subsequently became fixed to the bone by anchylosis, as in the pike and Lophius. This anatomical fact militates strongly against the idea that the *Labyrinthodon* is a Saurian.

Labyrinthodon pachygnathus.—The remains of this species, which have been obtained, consist of portions of the lower and upper jaws, an anterior frontal bone, a fractured humerus, an ilium with a great part of the acetabulum, the head of a femur, and two ungual phalanges. A portion, nine and a half inches long, of a right ramus of a lower jaw, in addition to the characters common to it and the fragment of the lower jaw of the *L leptognathus*, in the structure of the angular and dentary pieces, shows that the outer wall of the alveolar process is not higher than the inner, as in frogs and toads, the salamanders and menopome, in all of which the base of the teeth is anchylosed to the inner side of an external alveolar plate. The smaller serial teeth are about forty in number, and gradually diminish in size as they approach both ends, but chiefly so towards the anterior part of the jaw. The sockets are close together, and the alternate ones are empty. The great laniary teeth were apparently three in each symphysis, and the length of the largest is considered to have been one and a half inch. The base of each tooth is anchylosed to the bottom of its socket, as in scomberoid and sauroid fishes; but the *Labyrinthodon* possesses a still more ichthyic character in the continuation, preserved in this specimen, of a row of small teeth anterior and external to the two or three larger tusks. The premaxillary bone presents the same peculiar modification as in the higher organized Batrachia, the palatal process of the premaxillary extending beyond the outer plate both externally and, though in a less degree, internally, where it forms part of the boundary of the anterior palatal foramen, whence the outer plate rises in the form of a compressed process from a longitudinal tract in the upper part of the palatal process; it is here broken off near its margin, and the fractured surface gives the breadth of the base of the outer plate, stamping the fossil with a Batrachian character conspicuous above all the saurian modifications by which the essential nature of the fossil appears at first sight to be masked.

In the pre-frontal bone there are indications of crocodilian structure. Its superior surface is slightly convex and pitted with irregular impressions; and from its posterior and outer part it sends downwards a broad and slightly concave process, which appears to be the anterior boundary of the orbit. This process presents near its upper margin a deep pit, from which a groove is continued forwards; and in the corresponding orbital plate of the crocodile there is a similar but smaller foramen.

From these remains of the cranium of the *L. pachygnathus*, it is evident that the facial or maxillary part of the skull was formed in the main after the crocodilian type, but with well-marked batrachian modifications in the premaxillary and inferior maxillary bones. The most important fact which they show is, that this sauroid Batrachian had subterminal nostrils, leading to a wide and shallow nasal cavity, separated by a broad and almost continuous palatal flooring from the cavity of the mouth; indicating, with their horizontal position, that their posterior apertures were placed far behind the anterior or external nostrils: whereas in the air-breathing Batrachia the nasal meatus is short and vertical, and the internal apertures pierce the anterior part of the palate It may be inferred, therefore, that the apparatus for breathing by inspiration must have been present in the *Labyrinthodon* as in the crocodile; and hence still further, that the skeleton of the *Labyrinthodon* will be found to be provided with well-developed costal ribs, and not, as in most of the existing Batrachians, with merely rudimentary styles. Since the essential condition of this defective state of the ribs of Batrachians is well known to be their fish-like mode of generation and necessary distension of the abdomen, it is probable that the generative economy of these fossil reptiles, in which the more complete ribs would prevent the excessive enlargement of the ovaria and oviducts, may have been similar to that of saurian reptiles.

A fragment of a vertebra of *L. pachygnathus* presents analogous characters to the vertebra of the *L. leptognathus* previously noticed.

Of the few bones of the extremities which have come under the writer's inspection, one presents all the characteristics of the corresponding part of the humerus of a toad or frog, viz , the convex, somewhat transversely extended articular end, the internal longitudinal depression, and the well-developed deltoid ridge. The length of the fragment is two inches, and the breadth is thirteen lines. The ridges are moderately thick and compact, with a central medullary cavity. In its structure, as well as in its general form, the present bone agrees with the batrachian, and differs from the crocodilian type.

In the right ilium, about 6 inches in length, and in the acetabulum, there is a combination of crocodilian and batrachian characters. The acetabular cavity is bounded on its upper part by a produced and sharp ridge, as in the frog, and not emarginate at its anterior part, as in the crocodile.

As the fragment of the ilium was discovered in the same block as the two fragments of the cranium and the portion of the lower jaws, it is probable that they may have belonged to the same animal; and if so, as the portions of the head correspond in size with those of the head of a crocodile six or seven feet in length, but the acetabular cavity with that of a crocodile 25 feet in length, then the hinder extremities of the *Labyrinthodon* must have been of disproportionate magnitude compared with those of existing Saurians, but of approximate magnitude with some of the living anourous Batrachians That such a reptile, of a size equal to that of the species whose remains have just been described, existed at the period of the formation of the new red sandstone, is abundantly manifested by the remains of those singular impressions to which the term *Cheirotherium* has been applied. Other impressions, as those of the *Cheirotherium Hercules*, correspond in size with the remains of the *Labyrinthodon salamandroides*, which have been discovered at Guy's Cliff The head of a femur from the same quarry in which the ilium was found is shown to correspond in size with the articular cavity of the acetabulum. The two toe-bones, or terminal phalanges, resemble those of Batrachians in presenting no trace of a nail, and from their size they may be referred to the hind feet of the *L pachygnathus*.

An entire skull of the largest species discovered in the new red sandstones of Wurtemberg; a lower jaw of the same species found in the same formation in Warwickshire, some vertebræ, and a few fragments of bones of the limbs, have served, with the indications of size and shape of the trunk of the animal yielded by the series of consecutive foot-prints, as the basis of the restoration of the *Labyrinthodon salamandroides*, at the Crystal Palace. It is to be understood, however, that, with the exception of the head, the form of the animal is necessarily more or less conjectural.

Labyrinthodon scutulatus—The remains to which this specific designation has been applied compose a closely and irregularly aggregated group of bones imbedded in sandstone, and manifestly belonging to the same skeleton; they consist of four vertebræ, portions of ribs, a humerus, a femur, two tibiæ, one end of a large flat bone, and several small osseous dermal scutæ. The mass was discovered in the new red sandstone at Leamington, and was transmitted to the writer in the summer of 1840.

The vertebræ present bi-concave articular surfaces similar to those of the other species. In two of them the surfaces slope in a parallel direction obliquely from the axis of the vertebræ, as in the dorsal vertebræ of the frog, indicating a habitual inflexion of the spine, analogous to that in the humped back of the frog. The neurapophyses are anchylosed to the vertebral body. The spinous process rises from the whole length of the middle line of the neurapophysial arch, and its chief peculiarity is the expansion of its elongated summit into a horizontally-flattened plate, sculptured irregularly on the upper surface A similar flattening of the summit of the elongated spine is exhibited in the large atlas of the toad. The body of the vertebra agrees with that of the *L. leptognathus.* The humerus is an inch long, regularly convex at the proximal extremity, and expanded at both extremities, but contracted in the middle. A portion of a somewhat shorter and flatter bone is bent at a subacute angle with the distal extremity, and resembles most nearly the anchylosed radius and ulna of the Batrachia

The femur wants both the extremities; its shaft is subtrihedral and slightly bent, and its walls are thin and compact, including a large medullary cavity. The tibiæ are as long, but thicker and stronger than the femur. They had lost their articular extremities, but exhibited that remarkable compression of their distal portion which characterizes the corresponding bone in the Batrachia; they likewise have the longitudinal impression along the middle of the flattened surface. Were more of the skeleton of the above-defined species of *Labyrinthodon* known, they might present differences of subgeneric value. Such differences in the forms and proportions of the skull, and in the form and relative position of the orbits, of specimens that have been discovered subsequently in the triassic sandstones of Germany, have been so interpreted.

In the *Labyrinthodon* (*Mastodonsaurus*) *Jaegeri*—the largest of the species—the skull is triangular, the two condyles projecting from the middle of the base; the sides are straight, and converge to the obtuse apex. The orbits are oval, narrowest anteriorly, and are situated nearly midway between the fore and back part of the skull. The nostrils are very small, and are as wide apart as the orbits.

Labyrinthodon (*Trematosaurus*) *Braunii*, Von Meyer.—The name *Trematosaurus* was given by Braun to a labyrinthodont reptile, in reference to the parietal foramen, at that time deemed to be peculiar to it, but now known to be common to all the family. The genus was founded on an unusually perfect skull discovered in the richly fossiliferous bunter-sandstein of Bernburg. It is about one foot long, and, relatively to its basal breadth, it is longer and narrower than in *L Jagaeri*, the sides converging at a more acute angle. The orbits are elliptical, situated in the middle of the skull, and

Reptilia.

wider apart than in *L. Jagaeri*; the nostrils are relatively nearer together, their interspace being only half that in the *L. Jagaeri*.

Labyrinthodon (Metopius[1]*) diagnosticus*, H. von M.—In this species the skull is broader in proportion to its length than in the foregoing ;the sides are convex as they converge to the obtuse muzzle. The orbits are small, of a wide elliptical form, situated in the anterior third of the skull; they are twice as wide apart as are the nostrils. The parietal foramen is near the occipital ridge. The remains of this species are from the upper beds of the keuper standstone in Wirtemberg

The *Labyrinthodon (Capitosaurus) arenaceus*, Münster, is distinguished by a much broader and almost truncate muzzle. The orbits are elliptic, and situated almost wholly in the hinder third of the cranium; their interspace is the same as that between the nostrils, which are relatively as large as in *L. Braunii*.

The name *Zygosaurus* appears to have been applied with better grounds, by Eichwald, to a labyrinthodont reptile from the Permian cupriferous beds at Orenburg. It has the parabolic skull of *L. Jagaeri* and *L. diagnosticus*; the orbits large, and divided by an interval less than their own diameter. The temporal fossæ are relatively larger, and bounded by stronger zygomatic arches, and seem not to have been roofed over by bone. The dentition is strictly labyrinthodont.

Odontosaurus Voltzii is a genus and species founded by Von Meyer on a portion of a lower jaw, containing fifty teeth lodged in rather a deep groove, but apparently presenting the labyrinthic structure. The specimen is from the bunter sandstone of Soultz-les-Bains.

Xestorrhytias Perrini.—By this name M. von Meyer would indicate certain flat cranial bones, sculptured like those of *Labyrinthodon*, but with a peculiarly polished ganoid-like surface, from the muschelkalk of Lunéville.

In all the foregoing forms of Labyrinthodonts, represented by complete crania, with the exception perhaps of *Zygosaurus*, the supplemental osseous plates roofing over the temporal fossæ are present, as in *Archegosaurus*, viz., the "post-orbital" and the "super-squamosal" bones. In all of them the occipital condyles are distinct, forming a pair; and in all the vomer is divided and bears teeth. The structure and disposition of the entire dental system is strictly labyrinthodont.

The relation of these remarkable reptiles to the saurian order has been advocated to be one of close and true affinity, chiefly on the character of the extent of ossification of the skull, and of the outward sculpturing of the cranial bones. But the true nature of some of these bones appears to have been overlooked, and the glance of research for analogous structures has been too exclusively upward. If directed downward from the Labyrinthodonts to the *Archegosauri* and certain ganoid fishes, it suggests other conclusions.

The conformity of pattern in the dermal, semidermal, or neurodermal bones of the outwardly well-ossified skull of *Polypterus*, *Lepidosteus*, *Sturio*, and other salamandroid-ganoid fishes, with well-developed lung-like air-bladders, and of the same skull-bones in the *Archegosaurus* and the Labyrinthodonts; the persistence of the notochord (*chorda dorsalis*) in *Archegosaurus*, as in *Sturio*; the persistence of the notochord and branchial arches in *Archegosaurus*, as in *Lepidosiren*; the absence of occipital condyle or condyles in *Archegosaurus*, as in *Lepidosiren*; the presence of labyrinthic teeth in *Archegosaurus*, as in *Lepidosteus* and *Labyrinthodon*; the large median and lateral throat-plates in *Archegosaurus*, as in *Megalichthys*, and in the modern *Arapaima* and *Lepidosteus*;—all these characters point to one great natural group, peculiar for the extensive gradations of development, linking and blending together fishes and reptiles within the limits of such group. The salamandroid (or so-called "sauroid") Ganoids—*Lepidosteus* and *Polypterus*—are the most piscine, the true Labyrinthodonts are the most reptilian, of the group. The *Lepidosiren* and *Archegosaurus* are intermediate gradations, one having more of the piscine, the other more of the reptilian characters. The *Archegosaurus* conducts the march of development from the fish proper to the labyrinthodont type; the *Lepidosiren* conducts it to the perennibranchiate batrachian type. Both illustrate the artificiality of the supposed class distinction between fishes and reptiles, and the naturality of the "Hæmacrymes," or cold-blooded Vertebrata, as the one natural and truly definite group. There is nothing in the known structure of the so-named *Archegosaurus* or *Mastodonsaurus* that truly indicates a belonging to the saurian or crocodilian order of reptiles. The exterior ossifications of the skull and the canine-shaped labyrinthic teeth are both examples of the salamandroid modification of the ganoid type of fishes.

The small proportion of the fore limb of the *Mystriosaurus* in nowise illustrates this alleged saurian affinity; for though it be as short as in *Archegosaurus*, it is as perfectly constructed as in the crocodile, whereas the short fore limb of *Archegosaurus* is constructed after the simple type of that of the *Proteus* and *Siren*. But the futility of this argument of the sauroid affinities is made manifest by the proportions of the hind limb of *Archegosaurus*. As in *Proteus* and *Amphiuma*, it is as stunted as the fore limb; whereas in *Mystriosaurus*, as in other Teleosaurians, the hind limbs are relatively larger and stronger than in the existing crocodiles. M. von Meyer leaves the hind limb out of sight in his advocacy of the saurian nature of the so-called *Archegosaurus*. One regrets that Von Meyer's original name *Apateon*, though proposed to express his scepticism of the alleged nature of the fossil submitted to him in 1844 by Dr Gergens, was not retained by Professor Goldfuss. It is still more to be regretted that a compound name should in any case be adopted or constructed, where the proof of the affinity it may be meant to indicate is not perfect. *Archegosaurus*, like *Mastodonsaurus*, will become at length mere arbitrary terms; but until then, they will really recall or express little more than the mistaken views of the inventors of those names in respect of the true affinities of the remarkable extinct piscine reptiles to which they have been applied.

Fig. 68 gives a reduced view of a portion of new red sandstone, with three pairs of foot-prints in relief.

Consecutive impressions of such prints have been traced for many steps in succession in quarries of that formation in Warwickshire, Cheshire, and also in Lancashire, more especially at a quarry of a whitish quartzose sandstone at Storton Hill, a few miles from Liverpool. The foot-marks are partly concave and partly in relief; the former are seen upon the upper surface of the sandstone slabs, but those in relief are only upon the lower surfaces, being in fact natural casts, formed on the subjacent foot-prints as in moulds. The impressions of the hind foot are generally 8 inches in length and 5 inches in width; near each large footstep, and at a regular distance—about an inch and a half—before it, a smaller print of the fore foot, 4 inches long and 3 inches wide, occurs. The footsteps follow each other in pairs, each pair in the same line, at intervals of about 14 inches from pair to pair. The large as well as the small steps show the thumb-like toe alternately on the right and left side, each step making a print of five toes.

Foot-prints of corresponding form, but of smaller size, have been discovered in the quarry at Storton Hill, imprinted on five thin beds of clay, lying one upon another in the same quarry, and separated by beds of sandstone. From the lower surface of the sandstone layers the solid casts of each impression project in high relief, and afford models of the feet, toes, and claws of the animals which trod on the clay.

Similar foot-prints were first observed in Saxony, at the village of Hessburg, near Hillburghausen, in several quarries of a gray quartzose sandstone, alternating with beds of red sandstone, and of the same geological age as the sandstones

[1] This generic term has been applied to another fossil by Eichwald.

of England that had been trodden by the same strange animal. The German geologist who first described them proposed the name of *Cheirotherium* (*cheir*, the hand, *therion*, beast) for the great unknown animal that had left the foot-prints, in consequence of the resemblance, both of the fore and hind feet, to the impression of a human hand; and Dr Kaup conjectured that the animal might be a large species of the opossum kind. The discovery, however, of fossil skulls, jaws, teeth, and a few other bones, in the sandstones exhibiting the foot-prints in question, has rendered it more probable that both the foot-prints and the fossils are evidences of the same kind of huge extinct batrachian reptiles.

All the labyrinthodont remains from the Warwick and Leamington sandstones agree in their essentially batrachian nature with those from the German keuper, and other new red or triassic strata. The impressions of the *Cheirotherium* resemble those of the foot-prints of a Batrachian; but are not identical with those of any known Batrachian or other reptile. They show a papillose integument like that on the sole of certain Geckos, and which may be another mark of sauroid departure from the modern batrachian type. In the attempt to solve the difficult problem of the nature of the animal which has impressed the new red sandstone with the cheirotherian foot-prints, we cannot overlook the fact, that we have in the *Labyrinthodons* also batrachian reptiles, differing as remarkably from all known Batrachia, and from all other reptiles in the structure of their teeth; both the footsteps and the fossils are, moreover, peculiar to the new red sandstone; the different size of the foot-prints referred to different species of *Cheirotheria* correspond with the different size of ascertained species of *Labyrinthodon;* and the present facts best support the hypothesis, that the foot-prints called "cheirotherian," are those of labyrinthodont reptiles.

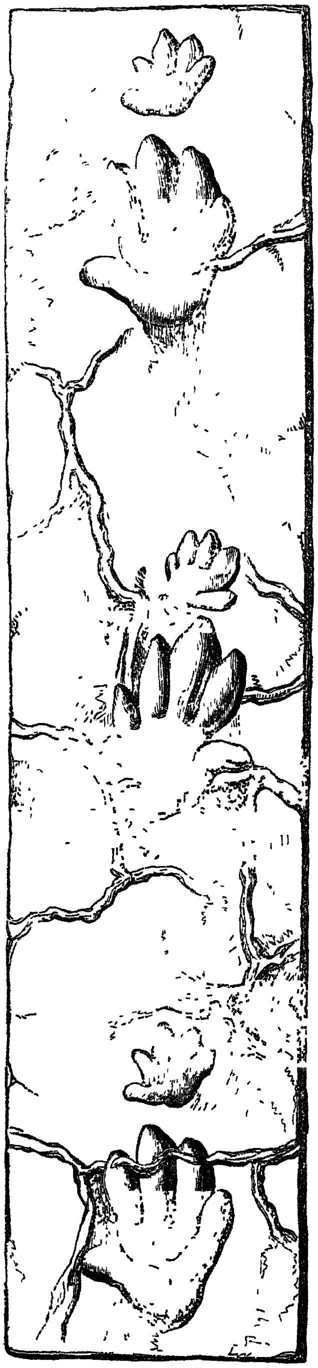

Fig. 68.
Foot-prints of *Labyrinthodon* (*Cheirotherium*).

Sub-class 2.—SAURIA.

ORDER I.—THECODONTIA.

Genus PROTOROSAURUS, Von Meyer.

Sp. *Protorosaurus Speneri*, Von M.—The first fossil Saurian on record is that which records the circumstance by its generic name, and honours its describer by the specific one. The slab of "copper-slate" from the Permian beds of Eisenach in Thuringia, displaying, either in fossils or impressions, the skull, vertebral column, and bones of the fore foot of the reptile in question, was figured and described by Spener, a physician at Berlin, in 1710.[1] The original specimen is now in the museum of the Royal College of Surgeons, London. It was obtained from a copper-mine near Eisenach, at a depth of 100 feet from the surface.

A second specimen, showing the two fore limbs, a hind limb, and part of the trunk, was described by Link in 1718.[2] Cuvier gives copies of portions of two other specimens in his *Ossemens Fossiles*.[3]

The healthy, honest mind of Spener is shown by the conclusions which he formed from the state of preservation of his specimen—"omnia, enim, minutissima etiam apophyses, spinæ," &c.,—and from its association with equally well-preserved remains of fishes, and even of the delicate leaves of plants, against the notions of those fossils merely simulating, and never having been, the living organisms which they represented—notions which were then advocated under the sounding phrase of "plastic force," as they have lately been under that of "prochronism." Spener's only doubt was, whether the reptile had been a crocodile or a lizard; but he inclined to the former view, on account of the proportions of the head to the trunk. He then enters upon speculations as to how a crocodile could have come into Germany; and shows the usual effect of a mind biassed by a hypothetical diluvial catastrophe, not demonstrated by observation and inductive research, and to the extent of such bias benumbed in the exercise of the faculty for the acquisition of natural truth.

The seven cervical vertebræ are proportionally larger than in any known recent or fossil terrestrial or aquatic Saurian; they resemble in this respect the cervical vertebræ of Pterodactyles; the tail is long, and its vertebræ differ from those of all other known reptiles, recent or fossil, in having the spinous processes bifurcate, diverging in the direction of the axis of the body.[4]

The muscular power of the neck is indicated by traces of bone tendons. The dorsal vertebræ exceed eighteen in number, and have higher spines than in the modern Monitors; the dorsal ribs are long, and longitudinally impressed. The hind limb is much longer than the fore limb, and the leg is longer, in proportion to the thigh and foot, than in the Monitors. The teeth are sharp-pointed, slender; there appear to be at least twenty in both upper and lower jaws in Spener's specimen.

The writer concludes, from the length and strength of the tail and the peculiar provision for muscular attachments in that part, and from the proportions of the hind limbs, that the *Protorosaurus* was of aquatic habits, and that the strength of its neck and head, and the sharpness of its teeth, enabled it to seize and overcome the struggles of the active fishes of the waters which deposited the old Thuringian copper-slates.

Genus THECODONTOSAURUS.

Sp. *Thecodontosaurus antiquus*.—In 1836 certain reptilian remains from the "dolomitic conglomerate" at Redland, near Bristol, were described by Messrs Riley and Stutch-

---

[1] *Miscellanea Berolinensia*, 4to, i., p. 99, figs. 24 and 25.

[2] *Acta Eruditorum*, 1718, p. 188, pl. ii.

[3] Ed. 8vo, 1836, pl. ccxxxvii., figs. 1 and 2.

[4] A character first pointed out in the writer's "Report on British Fossil Reptiles," *Trans. of Brit. Assoc.*, 1841, p. 155.

Reptilia. bury.[1] The matrix has been referred to the Permian period; it is now thought by some good observers to be not older than the triassic.

The teeth in these reptilian fossils are lodged in distinct sockets in *Thecodontosaurus*; they are arranged in a close-set series, slightly decreasing in size towards the posterior part of the jaw; each ramus of the lower jaw contained twenty-one teeth. These are conical, rather slender, compressed and acutely pointed, with an anterior and posterior finely-serrated edge, the serratures being directed towards the apex of the tooth, the outer surface is more convex than the inner one; the apex is slightly recurved; the base of the crown contracts a little to form the fang, which is subcylindrical

Genus PALÆOSAURUS, Riley and Stutchbury.—In the same formation as contained the jaw and teeth of the *Thecodontosaurus* two other teeth were separately discovered, differing from the preceding and from each other; the crown of one of these teeth measuring 9 lines in length and 5 lines in breadth It is compressed, pointed with opposite trenchant and serrated margins, but its breadth as compared with its length is so much greater than in the *Thecodontosaurus*, that upon it has been founded the genus *Palæosaurus*, and it is distinguished by the specific name of *platyodon*, from the second tooth, which is referred to the same genus under the name of *Palæosaurus cylindrodon*. The portion of the tooth of the *Palæosaurus cylindrodon* which has been preserved shows that the crown is subcompressed and traversed by two opposite finely-serrated ridges, as in the *Thecodontosaurus*; its length is 5 lines, its breadth at the base 2 lines.

The vertebræ associated with the two kinds of teeth above described are biconcave, with the middle of the body more constricted, and terminal articular cavities rather deeper than in *Teleosaurus*; but they are chiefly remarkable for the depth of the spinal canal at the middle of each vertebra, where it sinks into the substance of the centrum; thus the canal is wider, vertically, at the middle than at the two ends of the vertebra: an analogous structure, but less marked, obtains in the dorsal vertebræ of the *Rhynchosaurus* from the new red sandstone of Shropshire.

Besides deviating from existing lizards in the thecodont dentition and biconcave vertebræ, the Saurians of the dolomitic conglomerate also differ in having some of their ribs articulated by a head and tubercle to two surfaces of the vertebra, as at the anterior part of the chest in crocodiles and Dinosaurs. The shaft of the rib was traversed, as in the Protorosaur and Rhynchosaur, by a deep longitudinal groove. Some fragmentary bones indicate obscurely that the pectoral arch deviated from the crocodilian, and approached the lacertian or enaliosaurian type, in the presence of a clavicle and in the breadth and complicated form of the coracoid. The humerus appears to have been little more than half the length of the femur, and to have been, like that of the *Rhynchosaurus*, unusually expanded at the two extremities. The femur is chiefly remarkable for a third process or trochanter, just above the middle of the shaft, which shows a medullary cavity. The distal condyles are flattened, the outer one being the larger; there is a deep depression between them posteriorly, and a very light one anteriorly. The tibia, fibula, and metatarsal bones manifest, like the femur, the fitness of the Saurians for progression on land. The ungual phalanges are sub-compressed, curved downwards, pointed, and impressed on each side with the usual curved canal.

The general conclusions which may be drawn from the knowledge at present possessed of the osteology of the *Thecodontosaurus* and *Palæosaurus* are, in their thecodont type of dentition, biconcave vertebræ, double-jointed ribs, and proportionate size of the bones of the extremities, they are allied to the *Teleosaurus*; but that they combine a dinosaurian femur, a lacertian form of tooth, and structure of the pectoral and probably pelvic arch with these crocodilian characters, having distinctive modifications, as the moniliform spinal canal, in which, however, the almost contemporary Rhynchosaur participates. It would be interesting to ascertain whether the caudal vertebræ are characterized, as in the Thuringian Protorosaur, by double diverging spinous processes.

Genus BELODON, Von Meyer.

Sp. *Belodon Plieningeri*.—The reptile from the upper white keuper sandstone of Wirtemberg, described by Plieninger,[2] agrees in its essential characters so closely with the thecodont Saurians of the Bristol conglomerate as to add to the probability of both belonging to the same lower mezozoic period. Reptilia.

Three vertebræ are modified to afford adequate attachment to the iliac bones in *Belodon*, and this additional evidence of affinity to *Dinosauria* may have characterized also the English Thecodonts.

Genus CLADYODON, Ow.

Sp. *Cladyodon Lloydii*.—In the Memoir on the Triassic Red Sandstones of Warwick, by Murchison and Strickland, published in 1840, in the 2d series of the *Geological Transactions*, vol. v., a tooth, which is an extremely rare fossil in those English formations, was figured in pl. xxviii., fig. 6.

Having had the opportunity of studying the original specimen and fragments of some others of seemingly the same species from the new red sandstones of Warwick and Leamington, the writer recognised the affinity of the reptile with those teeth to the thecodont reptiles of the Bristol conglomerate, and indicated what appeared a generic modification of form by the term *Cladyodon*.[3]

The writer has subsequently received other specimens of the teeth characterizing this genus, which may be described as being two-edged, sub-compressed; the sides more or less convex, the edges more or less sharp, and frequently finely serrate; the crown slightly bent sideways, the inner side towards the mouth-cavity. The teeth are sometimes lancet-shaped, through convergence of the edges towards point; sometimes through one edge being convex and the other concave, the crown is slightly curved or sickle-shaped; sometimes through use, the point is blunted. The enamel is very thin, smooth, showing under the lens a slight longitudinal striation, forming wrinkles. The dentine is disposed in concentric layers; is not labyrinthic: the base of tooth shows a conical pulp-cavity. These teeth indicate a Saurian about 12 feet in length.

The writer cannot discern any generic, or even good specific distinctions, between the teeth from the Warwickshire keuper, on which in 1840 he founded the genus *Cladyodon*, and those from the Wirtemberg keuper, on which M. von Meyer in 1844 founded the genus *Belodon*. Both are nearly allied to *Palæosaurus*.

Genus BATHYGNATHUS, Leidy.

Sp. *Bathygnathus borealis*, Leidy.—Allied to the *Cladyodon* and *Belodon* by the shape of the teeth is the Saurian from the new red sandstone of Prince Edward's Island, North America, the generic and specific characters of which have been deduced by Dr Leidy[4] from a portion of lower jaw, containing seven teeth, but with interspaces from which others have been lost. The depth of the dentary bone is 5 inches; a peculiarity which suggested the generic name (*bathus*, deep, *gnathos*, jaw). The precise mode of implantation of the teeth is not described.

The fossil was discovered at a depth of 21 feet from the surface, in a red sandstone supposed to be of the same age as that of Connecticut, so remarkable for the various and singular foot-marks, referable, some to reptiles, and others to large birds.

ORDER II.—CRYPTODONTIA.

Genus RHYNCHOSAURUS, Ow.

Sp. *Rhynchosaurus articeps*, Ow.[5]—The fossils in which the above order, genus, and species of reptile have been based are from the new red sandstone (trias) of Shropshire. They occur at the Grinsill quarries, near Shrewsbury, in a fine-grained sandstone, and also in a coarse burr-sandstone; in the latter the writer found imbedded some vertebræ, portions of the lower jaw, a nearly entire skull,

[1] *Geological Transactions*, 2d series, vol. v., p. 344.

[2] Würtemb. naturf. Jahreshefte, viii., Jahrg. 1857, p. 389. Jaeger's *Phytosaurus* appears to have been founded on casts of the sockets of the teeth of *Belodon*.

Reptilia.

fragments of the pelvis and of two femora: in the fine-grained sandstone, vertebræ, ribs, and some bones of the scapular and pelvic arches are imbedded. The bones present a very brittle and compact texture; the exposed surface is usually smooth, or very finely striated, and of a light blue colour. The sandstones containing these bones occasionally exhibit impressions of footsteps which resemble those figured in the Memoir by Messrs Murchison and Strickland (*Geol. Trans.*, 2d series, vol. v., pl. xxviii. fig. 1), but differ in the more distinct marks of the claws, the less distinct impression of a web, the more diminutive size of the innermost toe, and an impression corresponding with the hinder part of the foot, which reminds one of a hind toe pointing backwards, and which, like the hind toe of some birds, only touched the ground with its point. The foot-prints are likewise more equal in size, and likewise in their intervals, than those figured by Messrs Murchison and Strickland: they measure from the extremity of the outermost or fifth toe to that of the innermost or first rudimental toe, about one inch and a half. They are the only foot-prints that have as yet been detected in the new red sandstone quarries at Grinsill. As the fossil bones have always been found nearly in the same bed as that impressed by the footsteps above described, they probably belong to the same animal.

Vertebræ.—Both articular surfaces of the centrum are concave, and are deeper than in the biconcave vertebræ of the extinct Crocodilians; the texture of the centrum is compact throughout.

The neural arch is anchylosed with the centrum, without trace of suture, as in most lizards: it immediately expands and sends outwards from each angle of its base a broad triangular process with a flat articular surface; the two anterior sufaces look directly upwards, the posterior ones downwards; the latter are continued backwards beyond the posterior extremity of the centrum; the tubercle for the simple articulation of the rib is situated immediately beneath the anterior oblique process. So far the vertebræ of the *Rhynchosaurus*, always excepting their biconcave structure, resemble the vertebræ of most recent lizards In the modification next to be noticed, they show one of the vertebral characters of the *Dinosauria.* A broad obtuse ridge rises from the upper convex surface of the posterior articular process and arches forwards along the neural arch above the anterior articular process, and gradually subsides anterior to its base: the upper part of this arched angular ridge forms, with that of the opposite side, a platform, from the middle line of which the spinous process is developed. Nothing of this kind is present in existing lizards; the sides of the neural arch immediately converge from the articular processes to the base of the spine, without the intervention of an angular ridge formed by the sides of a raised platform. The base of the spinous process is broadest behind, and commences there by two roots or ridges, one from the upper and back part of each posterior articular process. The anterior margin of the spinous process is thin and trenchant; the height of the spine does not exceed the antero-posterior diameter of its base; it is obliquely rounded off. The spinal canal sinks into the middle part of the centrum and rises to the base of the spine, so that its vertical diameter is twice as great at the middle as at the two extremities: this modification resembles in a certain degree that of the vertebræ of the *Palæosaurus* from the Bristol conglomerate.

The skull presents the form of a four-sided pyramid, compressed laterally, and with the upper facet arching down in a graceful curve to the apex, which is formed by the termination of the muzzle. The very narrow cranium, wide temporal fossæ on each side, bounded posteriorly by the parietal and the mastoid bones, and laterally by strong compressed zygomata; the long tympanic pedicle, descending freely and vertically from the point of union of the posterior transverse and zygomatic arches, and terminating in a convex pulley for the articular concavity of the lower jaw; the large and complete orbits, and the short, compressed, and bent down maxillæ, all combine to prove the fossil to belong to the lacertian division of the saurian order. The mode of articulation of the skull with the spine cannot be determined in the present specimen, but the lateral compression and the depth of the skull, the great vertical breadth of the superior maxillary bone, the small relative size of the temporal spaces, the vertical breadth of the lower jaw, prove that it does not belong to a reptile of the batrachian order. The shortness of the muzzle, and its compressed form, equally remove it from the Crocodilians. No Chelonian has the tympanic pedicle so long, so narrow, or so freely suspended to the posterior and lateral angles of the cranium.

Reptilia.

The general aspect of the skull differs, however, from that of existing Lacertians, and resembles that of a bird or turtle, which resemblance is increased by the apparent absence of teeth. The pre-maxillary bones, moreover, are double, as in crocodiles and Chelonians, but, with this exception, all the essential characters of the structure of the skull are those of the lizard.

The rami of the lower jaw are remarkable, as in *Bathygnathus*, for their great depth, but not the least trace of a tooth is discernible in the alveolar border of the dentary element.

The cranium has been preserved with the mouth in the naturally closed state, and the upper and lower jaws in close contact. In this state we must suppose that they were originally buried in the sandy matrix which afterwards hardened around them; and since lizards, owing to the unlimited reproduction of their teeth, do not become edentulous by age, we must conclude that the state in which the *Rhynchosaurus* was buried, with its lower jaw in undisturbed articulation with the head, accorded with its natural condition, while living, so far as the less perishable hard parts of its masticatory organs were concerned. Nevertheless, since a view of the inner side of the alveolar border of the jaws has not been obtained, we cannot be quite assured of the actual edentulous character of this very singular Saurian. The indications of a dental system are much more obscure in the *Rhynchosaurus* than in any existing Lacertian; the dentations of the upper jaw are absolutely feebler than in the chameleon, and no trace of them can be detected in the lower jaw, where they are strongest in the chameleon. The absence of the coronoid process in the *Rhynchosaurus*, which is conspicuously developed in all existing lizards, corresponds with the unarmed condition of the jaw, and the resemblance of the *Rhynchosaurus* in this respect to the *Chelys ferox*, would seem to indicate that the correspondence extended to the toothless condition of the jaws. The resemblance of the mouth to the compressed beak of certain sea-birds, the bending down of the curved and elongated pre-maxillaries, so as to be opposed to the deep symphysial extremity of the lower jaw, are further indications that the ancient Rhynchosaur may have had its jaws encased by a bony sheath, as in birds and turtles.

There are few genera of extinct reptiles of which it is more desirable to obtain the means of determining the precise modifications of the locomotive extremities than the *Rhynchosaurus.* The fortunate preservation of the skull has brought to light modifications of the lacertine structure leading towards Chelonia and birds which before were unknown; the vertebræ likewise exhibit very interesting deviations from the lacertian type. The entire reconstruction of the skeleton of the *Rhynchosaurus* may be ultimately accomplished, if due interest be taken in the collection and preservation of the fossils of the Grinsill quarries.

Genus OUDENODON, Bain.

Sp. *Oudenodon Bainii.*—The fossils on which the above genus and species are founded are from a bluish argillo-ferruginous limestone in South Africa, and form part of a collection transmitted to the British Museum by A. G. Bain, Esq.

One portion of the fossil skull includes all that part in advance of the temporal fossæ; the fore part of the temporal ridges, at the upper and back part of this fragment, curve as they diverge from each other to the back part of the orbit. The upper interorbital part of the cranium is nearly flat, with the orbital margins slightly raised, and terminating anteriorly in a low antorbital prominence; the least breadth of the interorbital space is 1 inch. A slight depression divides the antorbital from the supranasal tuberosities. The nasal bones form an almost flat rhomboid surface, from the contracted fore part of which the broad premaxillary part of the upper jaw inclines downward and forward at an open angle. This part is traversed by a low obtuse median ridge, and terminates below in a trenchant edentulous border.

The nostrils are small, oval, and separated from each other by the broad junction of the ascending branch of the premaxillary with them.

The maxillary bone presents the chief peculiarity, being traversed obliquely by a strong angular ridge, commencing a little anterior to the orbit, and terminating at the alveolar border, not far from the maxillo-premaxillary suture. The alveolar border gently curves to this termination, and shows no trace of a tooth or alveolus.

The compound structure of the lower jaw is shown at the fractured back part, where an upper (surangular ?) element, thick and rounded above, is received into an outer and lower element, thin above, and thick and bent below, forming a groove for the reception of the upper element. On the outer side of the jaw, about the middle of the part preserved, there is a longitudinal depression or

Reptilia.

narrow vacuity, above which there is a low ridge. The symphysis is thick, long, and bent up in the form of a beak, terminating by an edentulous sub-trenchant border; its fore and outer part is traversed by a low median ridge.

The length of this portion of the skull is 6 inches; its breadth across the maxillary ridges is 2 inches 10 lines; the extent of the symphysis of the lower jaw is 2 inches 6 lines Besides the evidence from the two nostrils, which removes the *Oudenodon*, like the *Rhynchosaurus*, from the chelonian order, Mr Bain, in a letter announcing the discovery of the fossils in South Africa, mentions the association of other bones with skulls, which gives additional proof of the saurian nature of the edentulous reptiles. He writes:[1]— "There were many skulls entirely without teeth, which we at first thought had belonged to Chelonians or turtles; but afterwards, finding that the animals had distinct narrow ribs, which Chelonians have not, we put them down also for something new, and named them "Oudenodons," or toothless animals.

ORDER III.—DICYNODONTIA.

Genus DICYNODON, Ow.—In 1844 Mr Andrew G. Bain, who had been employed in the construction of military roads in the colony of the Cape of Good Hope, discovered, in the tract of country extending northwards from the county of Albany, about 450 miles east of Cape Town, several nodules or lumps of a kind of sandstone, which, when broken, displayed in most instances evidences of fossil bones, and usually of a skull with two large projecting teeth. Accordingly these evidences of ancient animal life in South Africa were first notified to English geologists by Mr Bain under the name of "Bidentals;" and the specimens transmitted by him were submitted to the writer for examination. The results of the comparisons thereupon instituted went to show that there had formerly existed in South Africa, and from geological evidence, probably, in a great lake or inland sea, since converted into dry land, a race of reptilian animals presenting in the construction of their skull characters of the crocodile, the tortoise, and the lizard, coupled with the presence of a pair of huge sharp-pointed tusks, growing downwards, one from each side of the upper jaw, like the tusks of the mammalian morse or walrus. No other kind of teeth were developed in these singular animals: the lower jaw was armed, as in the tortoise, by a trenchant sheath of horn, some bones of the back, or vertebræ, by the hollowness of the co-adapted articular surfaces, indicate these reptiles to have been good swimmers, and probably to have habitually existed in water; but the construction of the bony passages of the nostrils proves that they must have come to the surface to breathe air.

Some extinct plants allied to the Lepidodendron, with other fossils, render it probable that the sandstones containing the dicynodont reptiles were of the same geological age as those that have revealed the remains of the Rhynchosaurs and Labyrinthodonts in Europe.

The generic name *Dicynodon* is from the Greek words signifying "two tusks or canine teeth." Three species of this genus have been demonstrated from the fossils transmitted by Mr Bain.

Sp. *Dicynodon lacerticeps*, Ow.[2]—This species is founded on a skull 6 inches in length, of which a reduced figure is given in cut 69, in which *C* shows the canine tusks.

Sp *Dicynodon testudiceps*, Ow.—In this species the skull, and the facial part more particularly, is shorter than in *D. lacerticeps*.

Sp. *Dicynodon strigiceps*, Ow.—The shortening of the jaws and blunting of the muzzle are carried to an extreme in this species, in which the nostrils are situated almost beneath the orbits.

Sp. *Dicynodon tigriceps*, Ow.[3]—In this species the length of the skull is 20 inches, its breadth across the widest part of the zygomatic arches being 18 inches. It differs from the *D. lacerticeps* not only in size, but in the relatively larger capacity of the temporal fossæ, and smaller size of the orbits. These cavities in *D. lacerticeps* occupy the middle third of the skull, but in *D. tigriceps* are wholly in the anterior half of the skull. The profile of the skull

Reptilia.

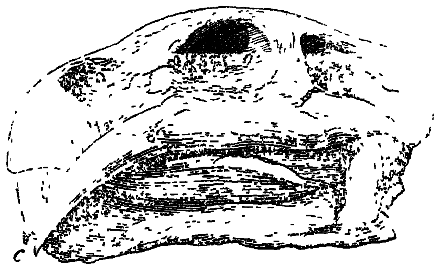

Fig. 69.

Skull and Tusks of *Dicynodon lacerticeps*.

in *D. lacerticeps* begins to slope or curve down from a line parallel with the back part of the orbits, but in *D. tigriceps* it does not begin to bend down until in advance of the orbits.

The vertebræ are bi-concave. The sacrum includes four or five vertebræ, which coalesce with unusually broad iliac bones. Some of the limb bones show a remarkable expansion of the distal end. The complete restoration of these most extraordinary bi-dental reptiles would be an extremely welcome addition to palæontology. No evidence of the genus has yet been met with out of South Africa. The English *Rhynchosaurus* seems, of all known European fossil reptiles, the most nearly akin to *Oudenodon* and *Dicynodon*.

ORDER IV.—ENALIOSAURIA [4]

The creatures called *Enaliosauria* or sea-lizards were vertebrate animals, or had back-bones, breathed the air like land-quadrupeds, but were "cold-blooded," or of a low temperature, like crocodiles and other reptiles. The proof that the Enaliosaurs respired atmospheric air immediately, and did not breathe water by means of gills like fishes, is afforded by the absence of the bony framework of the gill apparatus, and by the presence, position, and structure of the air-passages leading from the nostrils to the mouth, and also by the bony mechanism of the capacious chest or thoracic-abdominal cavity; all of which characters have been demonstrated by their fossil skeletons. With these characters the sea-lizards combined the presence of two pairs of limbs shaped like fins, and adapted for swimming.

The group of reptiles so termed includes all those which have any part of the thoracic-abdominal cavity encompassed by moveable ribs. The first character distinguishes them from the *Batrachia* and *Chelonia* with fin-shaped limbs

The *Enaliosauria*, however, do not form a strictly natural group, being based upon a single character relating to medium of life and locomotion. It is probable that the labyrinthodont reptiles may have had their limbs in structure and shape as paddles; but more important modifications of structure would keep them apart, like the lower *Batrachia* and the *Chelonia*, from the more lizard-like reptiles called *Enaliosauria*.

In this group there are two divisions,—one characterized by having five digits in the fin, the other by having more than that typical number. The pentadactyle division may be subdivided into those in which the ilio-pubic arch is attached to a sacrum and those on which it is freely suspended or not so attached. The polydactyle division presents a general type of structure more conformable with that of which the Archegosaurs and Labyrinthodonts manifest two phases of development, and in which the ascent from the gano-salamandroid fishes reaches its culminating point in *Ichthyosaurus*.

Sub-order 1.—SAUROPTERYGIA.

Genus NOTHOSAURUS, Münster.

Sp. *Nothosaurus mirabilis*, Münster.—In fig. 70 is given an analysis of the chief characters as yet ascertained of the species which may be regarded as the type of its family; by comparing this diagram with that of the *Archegosaurus* (fig. 65), the advance in the organization of the aquatic reptiles will be readily traced and understood.

The skull is no longer defended by a continuous covering of sculptured plate-bones; the vacuities behind the orbits for the temporal muscles are large and widely open. These vacuities are fenced externally by two long and slender horizontal bony bars;

[2] *Trans Geological Society*, 2d series, vol. vii. (*dis*, two, *kunodos*, canine-teeth).

[3] *Trans. Geol. Soc.*, 2d series, vol. vii., p. 233.

[4] From *ἐν, in, ἅλς, the sea, σαῦρος, a lizard.*

the upper one is formed by the mastoid (fig. 70, 8) and the postfontal (12), the lower one by the malar (27), and squamosal (28); the latter answering to the true zygomatic arch in Mammals. The squamosal abuts by its hinder expanded end against the almost vertical tympanic pedicle, which gives attachment to the lower jaw. This shows the reptilian compound structure: 29 marks the surangular element, 30 the angular one, 32 the dentary In the side-view of the skull in fig. 70, 22 is the premaxillary, 21 the maxillary, 15 the nasal—the cavity below being the nostril, 10 the prefontal—between which and 21 is the lacrymal, 11 the frontal above the orbit. The premaxillary teeth and corresponding premandibular ones are unusually long, strong, and sharp; there are two similar teeth in each maxillary; the remaining serial teeth are smaller, but equally acute. There are no teeth on the palate.

The almost entire and undisturbed vertebral column, from the muschelkalk of Bayreuth, figured by Von Meyer in pl. 23 of his work on muschelkalk Saurians, and attributed by him to *Nothosaurus mirabilis*, gives the earliest indication of that modification of the trunk-bones which reaches its maximum in the *Plesiosaurus* (fig. 72), in which it was first detected by the sagacity of Conybeare [1]

Twenty of the anterior vertebræ of this series, in *Nothosaurus*, which begins with the atlas, have the whole or part of the rib-pit situated on the centrum, as in the first vertebra in fig. 70; the pit is wholly there on fourteen vertebræ, it begins to ascend upon the neural arch in the fifteenth, as in the second vertebræ, given in fig. 70, and is wholly placed there on the twenty-first vertebra.

According, therefore, to the characters by which the writer has proposed [2] to distinguish the cervical from the dorsal vertebræ, *Nothosaurus* has twenty of the former. In the specimen referred to, nineteen consecutive vertebræ show the rib-pit supported

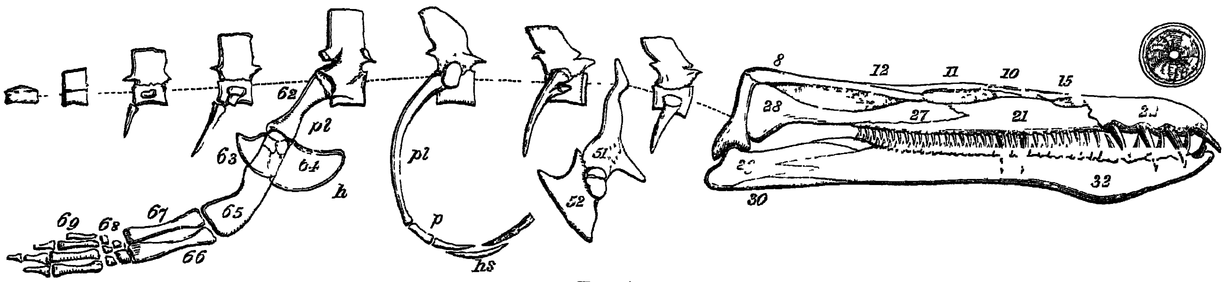

Fig. 70.

Nothosaurus (Trias)

wholly on an outstanding diapophysis from the neural arch, as in the third vertebra in fig. 70, these are to be reckoned therefore as dorsal vertebræ. In the cervical vertebræ the rib-pit is large, vertically reniform, not divided by a groove; its circumference slightly projects in *Nothosaurus*.

There is no clear evidence of any of the cervical ribs being terminally expanded and hatchet-shaped, as in *Plesiosaurus*; those of the back are vertically longer than in *Plesiosaurus*, and more convex.

In the sacral vertebræ, fourth in fig. 70, the rib-pits again begin to sink upon the centrum.

There are two distinct sacral vertebræ in *Nothosaurus*. They are known by their long, straight, terminally-bent, and convergent pleurapophyses, the first of which overlaps a little the second. To the convergent ends of these riblets, the ilium (fig. 70, 62, *pl*) was doubtless ligamentously affixed. In the first caudal vertebra the par- and di-apophyses stand out much farther than in the sacrum; but rapidly shorten in the second and third caudals. The compound process in each supports a short stiliform straight riblet, as in the fifth figured vertebra (fig 70); the anterior and succeeding caudals support hæmal arches and spines, after the disappearance of the pleurapophyses. The hæmal arch disappears in about the eighth vertebra from the end, and finally the neural arch. The terminal centrums are subelongate and subcompressed. Both *Nothosaurus* and *Pistosaurus* had abdominal ribs, of which the median piece (fig 70, *hs*) was subsymmetrical, the two rays diverging at a very open angle, and terminating in a point or a fork, the side-pieces (*p*) seem not to have been so numerous as in *Plesiosaurus*.

The scapula (fig. 70, 51) is a short and strong bone, its blade appearing as a short and narrow sub-compressed process extending from the subquadrate, thick and expanded end which affords the articular surfaces for the coracoid, clavicle, and humerus.

The clavicle, which is an exogenous process in *Plesiosaurus*, is here united by a strong oblique suture to the scapula. It expands into, or sends off from its outer part, a broad, flat, obtuse process, near the suture; then contracts and bends inwards to the episternum, to which it is articulated also by suture.

The coracoid (fig. 70, 52) sends forward a broad and short flattened process, separated by a narrow notch from the scapular part of its head; it then contracts and soon expands into a broad, flat, sub-triangular plate, the broad and straight border of which articulates with that of the opposite coracoid.

A wide unossified interval separates the coracoid from the episternum; their ossification in the direction of this interval gives the peculiar longitudinal or fore-and-aft extent to the coracoids of the Plesiosaur, in which these bones unite with the episternum.

The pelvic arch presents a closer correspondence with that in the *Plesiosaurus* (fig. 72).

The ischium (fig. 70, 63), contracting beyond its articular head, there expands into a flat subtriangular plate.

The pubis (fig. 70, 64) is a subcircular flat bone, with a notch near the articular end.

The bones of the limbs, although evidently those of fins or paddle-shaped extremities, are better developed than in *Plesiosaurus*, and more resemble the corresponding bones in the turtle (*Chelones*). The tuberosities or processes for muscular attachment near the head of the humerus (omitted in the diagram) are better marked, especially that on the concave side of the shaft; the distal end is thicker and less expanded. The whole bone is more curved than in any *Plesiosauri*. The femur (fig. 70, 65) is relatively longer and less expanded at its distal end. The bones of the fore arm, like those of the leg (fig. 70, 66 and 67), are longer than in *Plesiosaurus*. The articular surfaces present the foramina with raised borders, which characterize those in *Plesiosauri*, and which indicate the fibro-cartilaginous nature of the joints.

There is a ligamentous or unossified space at the back part of both carpus and tarsus (fig. 70, 68).

At present there is evidence of but four digits in both the fore and hind paddles of *Nothosaurus*; the metapodial and phalangeal bones are of the elongate flattened simple form, characteristic of supports of a tegumentary fin. One species of *Nothosaurus* (*N. Schimperi*, Von. M.) is from the lower division of the trias, called "grès bizarré" of Soulz-les-Bains; the other representatives of the genus (*N. giganteus*, *N. venustus*, *N Munsteri*, *N. Andriani*, *N. angustifros*, and *N. mirabilis*), are from the muschelkalk of Bayreuth and Luneville.

Genus PISTOSAURUS, Von Meyer.

Sp. *Pistosaurus longæous*—In this genus the facial part of the skull contracts abruptly in front of the orbits; so that, viewed from above, it resembles a long-necked bottle; the orbits are situated in the posterior half of the skull, and the nostrils are lateral. From the muschelkalk of Bayreuth.

Genus CONCHIOSAURUS, Von Meyer.

Sp. *Conchiosaurus clavatus.*—The facial part of the skull is less prolonged than in *Pistosaurus*, and the nostrils are terminal. The teeth are twelve in number on each side, are subequal, with widish intervals with pyriform crown. From the muschelkalk at Laineck, near Bayreuth

Genus SIMOSAURUS,[3] Von Meyer.

Sp. *Simosaurus Gaillardoti.*—The fossils, chiefly cranial, on which this genus is founded, occur in the dolomitic muschelkalk near Ludwigsberg, and in the muschelkalk of Luneville. The skull presents the large temporal fossæ, the divided nostrils, and the general depressed form and composition of that of *Nothosaurus* and *Pistosaurus*. But its facial part is much shorter; the muzzle is neither prolonged nor terminally expanded, but forms the obtuse

[1] *Trans. Geol. Soc.*, vol. vi., 1822, and vol. i., 2d series, p. 381, 1824.

[3] Σιμος, *snub-nosed, flat-nose.*

Reptilia.

end of the short depressed face, of which the premaxillary part is the narrowest. The nostrils, consequently, although distant from the orbits by half the diameter of the latter, are yet nearer the fore end of the skull than in the above-cited macrotrachelian genera. The nostrils are relatively nearer to each other, the intervening bony tract due to the premaxillaries chiefly being, relatively to the breadth of the skull, much narrower in *Simosaurus* than in *Notho-* or *Pisto-saurus*.

The profile of the skull rises from the internasal to the interorbital regions much more than in the Nothosaur, and the depths of the skull, behind the orbit, is greater in proportion to its length. The post-frontals are most clearly produced backwards, along the upper border of the zygoma to the mastoids. The malars are coextended, and connected with the post-frontals, but terminate freely and obtusely a little beyond the co-prolonged hind part of the maxillary, without being met by or joining a squamosal

Most complete and extensive is the ossification of the roof of the mouth in this genus. The pterygoids are expanded into one broad unbroken imperforate flat expanse of bone, from about one-third of the distance from the snout to the occipital condyle; they are united by a median suture, and underlap the whole of the sphenoid. The teeth, compared with *Nothosaurus*, are few and large, and are subequal, save one or two at the fore and hind extremity of the series. The crown expands a little above the fang, is conical, sub-bifurcate, and impressed by a few coarse longitudinal ridges; some are obtuse, others acute; but all are shorter and thicker than in *Notho-* or *Pisto-saurus*.

The vertebræ have flat or very slightly concave articular surfaces on the body; the neural arch articulates therewith by suture. In these characters, and in their general proportions, they resemble those of *Notho-* and *Plesio-saurus*. It is significant of some difference in respect of the arrangement of the vertebræ in the same column, that although specimens from the tail, and from different parts of the back, have been obtained, no cervical vertebra with any probability belonging to this genus has yet been found. The caudal centrum presents two well-defined, rather prominent, hypapophyses for the hæmal arch. The coracoid in the contraction of the body reminded Cuvier of that of the *Ichthyosaurus*, but its expanded median part was differently shaped. The pubis, like that of the *Plesiosaurus*, resembles to a certain degree the pubis in *Chelonia*. The few bones of the limbs which have been found still more resemble, as do those of *Pistosaurus*, the corresponding bones of marine *Chelonia*.

Accordingly, there have been entered in palæontological catalogues an *Ichthyosaurus Lunevillensis* (De la Beche), a *Plesiosaurus Lunevillensis* (Münster), and a *Chelonia Lunevillensis* (Gray and Keferstein); but all these are parts of one and the same genus of Enaliosaurian, the "Saurien des environs de Lunéville" of Cuvier, the "Simosaurus" of H. von Meyer.

Genus PLACODUS.—The cranial structure in this genus of muschelkalk reptile is closely similar to that in *Simosaurus*, but its proportions are different; it is as broad as long; the greatest breadth being behind, whence the sides converge to an obtuse muzzle; the entire figure viewed from above being that of a right-angled triangle, with the corners rounded off The temporal fossæ are the widest, and zygomatic arches the strongest, in the whole class *Reptilia;* the lower jaw presents a like excessive development of the coronoid processes. These developments, for great size and power of action of the biting and grinding muscles, relate to a most extraordinary form and size of the teeth, which resemble paving-stones, and were evidently adapted to crack and bruise shells and crusts of marine Invertebrata.

The teeth of the upper jaw consist of an external or maxillary series, and an internal or palatal series. The maxillary series are supported in a marginal row of alveoli by the premaxillary and maxillary bones; the palatal series are implanted in the palatine and pterygoid bones. The maxillo-premaxillary teeth are five in number on each side, two implanted in the premaxillary, and three in the maxillary. The premaxillary teeth are subequal, smaller than the maxillary teeth; their crowns are subhemispheric in *P. laticeps*, but in *P. Andriani* they present bent, pointed, prehensile character. In *P. laticeps* the first maxillary tooth has a full oval crown, 4½ lines by 4 in diameter; the second measures 5½ lines by 4½ lines in diameter; the third is subcircular, 8 lines in diameter, on the right side. The palatal series begins on the inner side of this tooth, and consists of two teeth on each side. The first tooth has a full elliptical crown, 10 lines by 8; the second tooth, developed in the broad pterygoid bone, presents a full oval shape, 1 inch 9 lines by 1 inch 3 lines in diameter. In *Placodus gigas* and P. *Andriani* the palatal teeth, three in number on each side, are all of large size, slightly increasing from before backwards; they are situated close together, forming on each side a series a little curved with the convexity outwards, and the interspace between the two series is very narrow. The first tooth is triangular, the second and third are quadrangular; each with the angles rounded, and the transverse diameter exceeding the fore and aft or longitudinal one. The maxillary teeth are much smaller than the palatal ones, have a rounded or subquadrate crown, are four in number, and of subequal dimensions. The premaxillary teeth, three in number on each side, are more remote and distinct from the maxillary teeth than in *Placodus rostratus* and *P. laticeps*; their crowns are more elongated and conical than in *P. laticeps;* the prehensile power of the prolonged premaxillary part of the jaw being obviously greater in *Placodus gigas* than in *P. laticeps* or *P. rostratus*. The size of the last tooth in *P. laticeps* surpasses that of any of the teeth in the previously discovered species. In proportion to the entire skull, it is the largest grinding tooth in the animal kingdom, the elephant itself not excepted

All these teeth are implanted by short simple bases in distinct hollow sockets, subject to the same law of displacement and succession as in other reptiles. By some it may be deemed requisite to separate generically the *Placodi* with two teeth from those with three teeth in each palatal series; but the *Placodus rostratus* offers a transitional condition in the small relative size of the first two palatal teeth, and in the rounded form of all the teeth, from the *P. Andriani* to the *P. laticeps*.

We cannot contemplate the extreme and peculiar modification of form of the teeth in the genus *Placodus* without a recognition of their adaptation to the pounding and crushing of hard substances, and a suspicion that the association of the fossils with shell-clad Mollusks in such multitudes as to have suggested special denominations to the strata containing *Placodus* (*e.g*, muschelkalk, terebratulitenkalk, &c), is indicative of the class whence the *Placodi* derived their chief subsistence.

No doubt the most numerous examples of similarly-shaped teeth for a like purpose are afforded by the class of fishes, as, *e g*, by the extinct Pycnodonts, and by the wolf-fish (*Anarrhichas lupus*) and the Cestracion of the existing seas. But the reptilian class is not without its instances at the present day of teeth shaped like paving-stones, of which certain Australian lizards exhibit this peculiarity in so marked a degree that the generic name *Cyclodus* has been invented to express that peculiarity. Amongst extinct reptiles, also, a species of lizard from the tertiary deposits of the Limagne in France presents round obtuse teeth, of which the last, in the lower jaw, is suddenly and considerably larger than the rest.

Nothosaurus, *Simosaurus*, and *Pistosaurus* present the same evidences of lacertian affinities in the division of the nostrils by the median extension of the premaxillary backwards to the nasals, the same thecodont dentition, and the same circumscription of the orbits and temporal fossæ as in *Placodus:* there is also a general family likeness in the upward aspect of these apertures, accompanying an extreme depression of the skull. The muzzle, though varying greatly in length in these genera, presents the same obtuseness; and the alveolar border of the jaws the same smooth outward convexity which we observe in the *Placodus*. The peculiar confluence of the elements of the upper and lower zygomatic arches,—*i.e.*, of post-frontal and malar,—forming the broad wall of bone behind the orbit, is continued still further backwards in the *Simosaurus*. In *Pistosaurus* the elongated post-frontal, malar, and squamosal are united together in one deep zygomatic arch, which has the mastoid and tympanic for its hinder abutment.

It is remarkable that hitherto no vertebræ or other bones of the trunk or limbs have been found so associated with the teeth of *Placodus*, as to have suggested their belonging to the same species. Usually, after the indication of a reptile by detached teeth, the next step in its reconstruction is based upon detached vertebræ. The twelve or more evidences of *Placodus*, afforded by bone as well as tooth, are all portions of the skull.

It is possible that some of the singularly modified vertebræ from the muschelkalk, next to be described, may belong to the *Placodus;* and the same surmise suggests itself in reference to some of the limb-bones from the muschelkalk that cannot be assigned to other known saurian genera.

The obvious adaptation of the dentition of *Placodus* to the crushing of very hard kinds of food, its close analogy to the dentition of certain fishes known to subsist by breaking the shells of whelks and other shell-clad Mollusks, and the characteristic abundance of fossil shells in the strata to which the remains of *Placodus* are peculiar, concur in producing the belief that the species of this genus were reptiles frequenting the sea-shore, and probably good swimmers. But as at present we have got no further than the head and teeth in the reconstruction of this mezozoic form of molluscivorous reptile, the present notice will conclude with a remark suggested by the disposition and form of the teeth. In all the species, under the rather wide range of specific varieties of the dentition, there are two rows of the crushing teeth in the upper jaw, and only one row in the lower jaw, on each side of the mouth; and the lower

Reptilia.

row plays upon both upper rows, with its strongest (middle) line of force directed against their interspace. Thus the crushing force below presses upon a part between the two planes or points of resistance above, on the same principle on which we break a stick across the knee; only here the fulcrum is at the intermediate point, the moving powers at the two parts grasped by the hands. It is obvious that a portion of shell pressed between two opposite flat surfaces might resist the strongest bite, but subjected to alternate points of pressure its fracture would be facilitated [1]

Genus TANYSTROPHÆUS.

Sp. *Tanystrophæus conspicuus*, H. von Meyer.—Certain long,

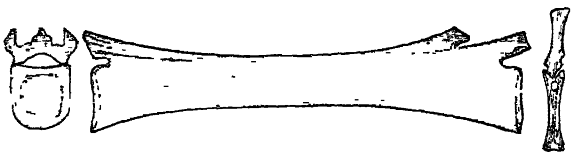

Fig. 71.
Tanystrophæus (Trias).

slender, hollow bones, from the German muschelkalk strata, were referred by Count Munster to the class *Reptilia*, under the name of *Macroscelosaurus*, under the impression that they were bones of the limbs. H. von Meyer subsequently, in more perfect specimens, observing that each slightly expanded extremity of the long bone was terminated by a symmetrical oval concave articular surface, surmounted by a pair of symmetrical lateral incurved plates, resembling confluent neurapophyses, with articular surfaces, and with their sometimes confluent bases arching over a neural canal (as in the left-hand figure in cut 71), recognised their vertebral character; and, adopting the determination of their reptilian nature, but repudiating the idea of their being limb-bones, he discarded Münster's name, and substituted for it that of *Tanystrophæus*,[2] indicative of their peculiar proportions as vertebræ. Although the articular ends are for the most part symmetrical, the long intervening body is not so. It is subcompressed, usually broader and flatter below than above; sometimes more flattened on one side than on the other, giving an irregular, vertically oval, or triangular cross section. A low median ridge is not uncommon on the lower surface towards the ends of the vertebra; and similar less regular ridges project from the sides of the otherwise smooth outer surface. The centrum is excavated by a canal, resembling a medullary one, but more probably filled, in the recent state, as in the long caudal style of the frog, with unossified cartilage. The walls of this cavity are compact, and in thickness about one-sixth of the diameter of the bone. The terminal neural arches support each a low median ridge or rudimental spine, which soon subsides. The trace of neural canal in like manner disappears, or is continued by two distinct slender canals which traverse for a certain extent the substance of the thicker upper wall of the cavity of the vertebral body. A single large vascular canal opens on the wider surface midway between the two ends of the body. There is no trace of transverse processes, rib-surfaces, or hæmapophyses; this, and the absence of the continuous neural canal, indicate these singular vertebræ to belong to the tail. From the long caudo-vertebral style of anourous Batrachia the vertebræ of *Tanystrophæus* differ in having distinct articular surfaces at both ends. The difference of shape and size in the few that have been found also indicates that there were more than two such vertebræ in the tail of the extraordinary animal to which they have belonged. Caudal vertebræ of the normal proportions and structure, from muschelkalk of the same localities with *Tanystrophæus* have been referred to *Nothosaurus*. It is possible, however, that one or other of the remarkable genera—*Simosaurus*, *Placodus*, e g.—may have possessed the peculiar structure in the tail, or some part of it, which the tanystrophæan vertebræ indicate. The first four vertebræ of the neck or trunk of the *Fistularia tabaccaria* are those which most resemble in their proportions the vertebræ above described; but none of the fistularian vertebræ have the articular concavity, and the zygapophyses, at both ends; the first presents them at the fore end, and the last at the hind end, and the modifications of both these finished articular ends pretty closely correspond with those of *Tanystrophæus*; but the second and third vertebræ of *Fistularia* are united with the first and fourth by sutural surfaces with deeply-interlocking pointed processes.

Genus SPHENOSAURUS.

Sp. *Sphenosaurus Sternbergii*, Von M.—The fossil vertebræ on which this genus is founded are imbedded in a sandstone, most like the bunter, from Bohemia or the south of Germany. Of the twenty-three vertebræ so preserved in nearly their natural position, and with their under surface exposed, five belong to the tail, the rest to the trunk. Of these, two are sacral, two lumbar, the rest are dorsal or thoracic, with long and slender ribs connected with them. The neural arch appears to have been suturally united to the centrum with large zygapophyses. The articular end of the centrum is vertical to its axis; both are slightly concave. Between each centrum is a transversely oval, depressed ossicle, homologous with the cervical wedge-bones or hypapophyses in Enaliosaurs. This is the chief peculiarity in *Sphenosaurus*, and recalls a character in the vertebral column of *Archegosaurus*.

Genus PLESIOSAURUS.—The discovery of this genus forms one of the most important additions that geology has made to comparative anatomy. Baron Cuvier deemed the structure of the Plesiosaur "to have been the most singular, and its characters the most anomalous that had been discovered amid the ruins of a former world." "To the head of a lizard it united the teeth of a crocodile, a neck of enormous length, resembling the body of a serpent, a trunk and tail having the proportions of an ordinary quadruped, the ribs of a chameleon, and the paddles of a whale." "Such," writes Dr Buckland, "are the strange combinations of form and structure in the *Plesiosaurus*, a genus, the remains of which, after interment for thousands of years amidst the wreck of millions of extinct inhabitants of the ancient earth, are at length recalled to light by the researches of the geologist, and submitted to our examination, in nearly as perfect a state as the bones of species that are now existing upon the earth."

The first remains of this animal were discovered in the lias of Lyme Regis about the year 1822, and formed the subject of the paper by the Rev. Mr Conybeare (afterwards dean of Llandaff), and Mr (afterwards Sir Henry) De la Beche, in which the genus was established, and named *Plesiosaurus* ("approximate to the Saurians"), from the Greek words, *plesios* and *sauros*, signifying "near" or "allied to," and "lizard," because the authors saw that it was more nearly allied to the lizard than was the *Ichthyosaurus* from the same formation.

The entire and undisturbed skeletons of several individuals, of different species, have since been discovered, fully confirming the sagacious restorations by the original discoverers of the *Plesiosaurus*.

Vertebral Column.—The vertebral bodies have their terminal articular surfaces either flat or slightly concave, or with the middle of such cavity a little convex. In general the bodies present two pits and holes at their under part. The cervical vertebræ consist of centrum, neural arch, and pleurapophyses. The latter are wanting in the first vertebra; but both this and the second have the hypapophyses.

The cervical ribs are short, and expand at their free end, so as to have suggested the term "hatchet-bones" to their first discoverers. They articulate by a simple head to a shallow pit, which is rarely supported on a process, from the side of the centrum; but is commonly bisected by a longitudinal groove, a rudimental indication of the upper and lower processes which sustain the cervical ribs in *Crocodilia*.

The body of the atlas articulates with a large hypapophysis below, with the neurapophysis above, with the body of the axis behind, and with part of the occipital condyle in front; all the articulations save the last become, in *Plesiosaurus pachyomus*, and probably with age in other species, obliterated by anchylosis. The hypapophysis forms the lower two-thirds, the neurapophysis contributes the upper and lateral parts, and the centrum forms the middle or bottom of the cup for the occipital condyle. The second hypapophysis is lodged in the inferior interspace between the bodies of the atlas and axis; it becomes anchylosed to these and to the first hypapophysis. The first pleurapophysis, or rudimental rib, is developed from the centrum of the axis.

As the cervical vertebræ approach the dorsal, the lower part of the costal pit becomes smaller, the upper part larger, until it forms the whole surface, gradually rising from the centrum to the neurapophysis.

The dorsal region is arbitrarily commenced by this vertebra, in which the costal surface begins to be supported on a diapophysis, which progressively increases in length in the second and third dorsal, continues as a transverse process to near the end of the trunk; and on the vertebra above or between the iliac bones, it subsides to the level of the neurapophysis. In the caudal vertebra the costal surface gradually descends from the neurapophysis upon the side of the centrum; it is never divided by the longitudinal groove which, in most *Plesiosauri*, indents that surface in

[1] Previous to the writer's Memoir on *Placodus* in the *Philosophical Transactions* (1858), all palæontologists had referred the genus to the pycnodont order of fishes.

[2] From *τανύω, to elongate, στρέφω, verto.*

the cervical vertebræ. The neural arches remain long unanchylosed with the centrum in all *Plesiosauri*, and appear to be always distinct in some species. The pleurapophyses gain in length, and lose in terminal breadth in the hinder cervicals; and become long and slender ribs in the dorsal region, curving outwards and downwards so as to encompass the upper two-thirds of the thoracic abdominal cavity. They decrease in length and curvature as they approach the tail, where they are reduced to short straight pieces, as in the neck, but are not terminally expanded; they cease to be developed near the end of the tail. The hæmapophyses in the abdominal region are subdivided, and with the hæmal spine or median piece, form a kind of "plastron" of transversely-extended, slightly-bent, median and lateral, overlapping, bony bars, occupying the subabdominal space between the coracoids and pubicals. In the tail the hæmapophyses are short and straight, and remain re-united both with the centrum above and with each other below. The hæmal spine is not developed in this region. This modification has been expressed by the statement that there were no chevron-bones in the Plesiosaur. The tail is much shorter in the *Plesio-* than in the *Ichthyo-saurus*.

The skull is depressed; its length is rather more than thrice its breadth; but the proportions somewhat vary in different species. The cranial part, or that behind the orbits, is quadrate; thence it contracts laterally to near the maxillo-premaxillary suture, where it continues either parallel or with a slight swelling before rounding into the obtuse anterior termination.

The orbits are at or near the middle of the skull, estimating the length of this by that of the lower jaw, they are in advance of the middle in *Plesiosaurus Hawkinsii*. The orbits are rather subtriangular than round, being somewhat squared off behind, straight above, and contracted anteriorly. No trace of sclerotic plates has yet been discerned in any specimen. The temporal fossæ are large subquadrate apertures. The nostrils, which are a little in advance of the orbits, are scarcely larger than the parietal foramen. Beneath them, upon the palate, are two similar-sized apertures, probably the palatal nostrils.

The lower jaw presents an angular, surangular, splenial, and dentary element, in each ramus; the dentary elements being confluent at the expanded symphysis. There is no vacuity between the angular and surangular or any other element of the jaw. The coronoid process is developed, as in *Placodus*, from the surangular, but rises only a little higher than in crocodiles. The alveoli are distinct cavities, and there is a groove along the inner border in both jaws.

When the successional teeth first project in that groove they give the appearance of a double row of teeth. All the teeth are sharp-pointed, long and slender, circular in cross section, with fine longitudinal ridges on the enamel; the anterior teeth are the longest.

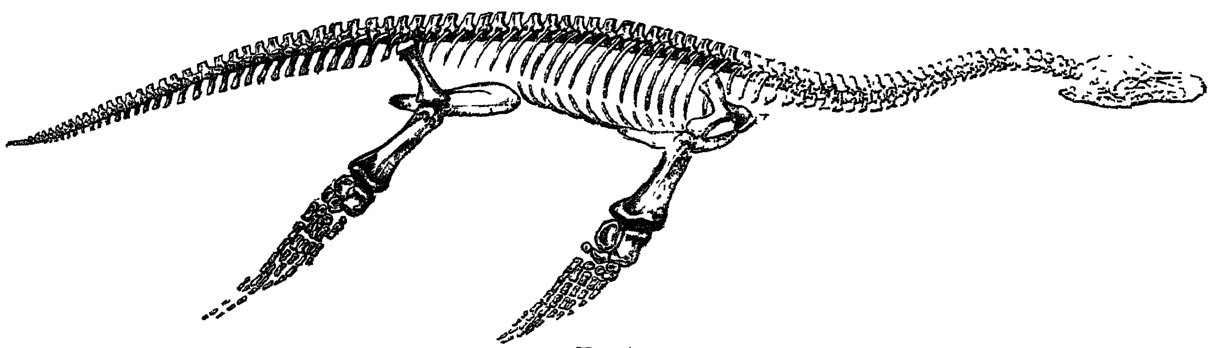

Fig. 72.

Plesiosaurus (Lias).

The scapula is a strong triradiate bone, the longest ray being formed by the acromial or clavicular process which arches forward and inward to abut against the sternum or epicoracoid.

The proper body of the scapula[1] is short and straight, somewhat flattened; the thick articular end, which forms the shortest ray, is subequally divided by the articular surface for the coracoid, and that for the head of the humerus.

The coracoids are chiefly remarkable for their excessive expansion in the direction of the axis of the trunk, extending from the abdominal ribs forward, so as to receive the entosternum, which is wedged into their anterior interspace. The median borders meet and unite for an extent determined by their degree of curvature or convexity, which is always slight.

The coracoids unite anteriorly with the clavicles as well as with the episternum; laterally they articulate with the scapula, combining to form the glenoid cavity for the humerus.

The episternum has the same general form as the median pieces of the abdominal ribs, being, like those pieces, a modified hæmal spine, only more advanced in position; the lateral wings or prolongations are broader and flatter; the median process is short; a longitudinal ridge projects from the middle of the internal surface. The humerus is a moderately thick and long bone, with a convex head, sub-cylindrical at its proximal end, becoming flattened and gradually expanded to its distal end, where it is divided into two indistinct surfaces for the radius and ulna. The shaft in most species is slightly curved backwards, or the hind border is concave, whilst the front one is straight. The radius and ulna are about half the length of the humerus; the former is straight, the latter curved or reniform, with the concavity towards the radius; both are flattened; the radius is a little contracted towards its carpal end, and in some species is longer than the ulna. The carpus consists of a double row of flat rounded discs,—the largest at the radial side of the wrist; the ulnar or hinder side appearing to have contained more unossified matter. The metacarpals, five in number, are elongate, slender, slightly expanded at the two ends, flattened, and sometimes a little bent. The phalanges of the five digits have a similar form, but are smaller, and progressively decrease in size; the expansion of the two ends, which are truncate, makes the sides or margins concave. The first or radial digit has generally three phalanges, the second from five to seven, the third eight or nine, the fourth eight, the fifth five or six phalanges. All are flattened; the terminal ones are nailless; and the whole were obviously included, like the paddle of the porpoise and turtle, in a common sheath of integument. The pelvic arch consists of a short but strong and straight narrow moveable ilium, and of a broad and flat pubis and ischium; the former subquadrate or subcircular, the latter triangular; the fore-and-aft expanse of both bones nearly equals that of the coracoids. All concur in the formation of the hip-joint. The ischium and pubis again unite together near their mesial borders, leaving a wide elliptic vacuity, or "foramen ovale" between this junction and their outer acetabular one. The pelvic paddle is usually of equal length with the pectoral one, but in *P. macrocephalus* it is longer. The bones closely correspond, in number, arrangement, and form, with those of the fore limb. The femur has the hind margin less concave, and so appears more straight. The fibula, in its reniform shape, agrees with its homotype the ulna. The tarsal bones are also smallest on the tibial side. Of existing reptiles, the lizards, and amongst these the old world Monitors (*Varanus*, Fitz.), by reason of the cranial vacuities in front of the orbits, most resemble the Plesiosaur in the structure of the skull. The division of the nostrils, the vacuities in the occipital region between the exoccipitals and tympanics, the parietal foramen, the zygomatic extension of the post-frontal, the palato-maxillary, and pterygo-sphenoid vacuities in the bony palate, are all lacertian characters, as contradistinguished from crocodilian ones.

But the antorbital vacuities between the nasal, pre-frontal, and maxillary bones are the sole external nostrils in the Plesiosaurs; the zygomatic arch abuts against the fore part of the tympanic, and fixes it. A much greater extent of the roof of the mouth is ossified than in lizards, and the palato-maxillary and pterygo-sphenoid fissures are reduced to small size. The teeth, finally, are implanted in distinct sockets. That the Plesiosaur had the "head of a lizard" is an emphatic mode of expressing the amount of resem-

[1] This is omitted in most of the published restorations of the *Plesiosaurus*.

Reptilia.

blance in their cranial conformation. The crocodilian affinities, however, are not confined to the teeth, but extend to the structure of the skull itself.

In the simple mode of articulation of the ribs, the lacertian affinity is again strongly manifested; but to this vertebral character such affinity is limited; all the others exemplify the ordinal distinction of the Plesiosaurs from known existing reptiles. The shape of the joints of the centrums; the number of vertebræ between the head and tail, especially of those of the neck; the slight indication of the sacral vertebræ; the non-confluence of the caudal hæmapophyses with each other, are all "plesiosauroid." In the size and number of abdominal ribs and sternum may perhaps be discerned a first step in that series of development of the hæmapophyses of the trunk which reaches its maximum in the plastron of the Chelonia.

The connation of the clavicle with the scapula is common to the *Chelonia* with the *Plesiosauri*; the expansion of the coracoids—extreme in *Plesiosauri*—is greater in *Chelonia* than in *Crocodilia*, but is still greater in some *Lacertia*. The form and proportions of the pubis and ischium, as compared with the ilium, in the pelvic arch of the *Plesiosauri*, find the nearest approach in the pelvis of marine Chelonia; and no other existing reptile now offers so near, although it be so remote, a resemblance to the structure of the paddles of the Plesiosaur. Amongst the many figurative illustrations of the nature of the Plesiosaur in which popular writers have indulged, that which compares it to a snake threaded through the trunk of a turtle is the most striking; but the number of vertebræ in the Plesiosaur is no true indication of affinity with the ophidian order of reptiles.

The reptilian skull from formations underlying the lias, to which that of *Plesiosaurus* has the nearest resemblance, is the skull of the *Pistosaurus*, from the German muschelkalk.[1] The nostrils have a similar position and diminutive size in *Pistosaurus*, but are somewhat more in advance of the orbits, and the premaxillaries enter into the formation of their boundary: the premaxillary muzzle and the temporal fossæ are also somewhat longer and narrower.

The post-frontals and mastoids more clearly combine with malars and squamosals in forming the zygomatic arch, which is of greater depth in *Pistosaurus*. the parietal foramen is larger: there is no trace of a median parietal crest. On the palate, besides the vacuities between the pterygoids and presphenoids, and the small foramina between the palatines, premaxillaries, and maxillaries, there is in *Pistosaurus* a single median foramen in advance of the latter foramina, between the pointed anterior ends of the pterygoids and the premaxillaries. In *Nothosaurus* the pterygoids extend back, underlapping the basi-sphenoid, as far as the basi-occipital, the median suture uniting them being well marked to their termination; and there is no appearance of vacuities like the pterygo-sphenoid ones in *Plesio-* and *Pisto-saurus*.

The tympanics are relatively longer, and extend farther back in *Pisto-* than in *Plesio-saurus*. There is no trace of lacrymals in *Pistosaurus*; and its maxillaries are relatively larger than in *Plesiosaurus*. In *Pistosaurus* there are 18 teeth on each side the upper jaw, including the 5 premaxillary teeth; in *Plesiosaurus* there are from 30 to 40 teeth on each side. In *Pistosaurus* the teeth are relatively larger, and present a more oval transverse section: the anterior teeth are proportionally larger than the posterior ones than they are in *Plesiosaurus*. The disproportion is still greater in *Nothosaurus*, in some species of which the teeth behind the premaxillary and symphysial terminal expansions of the jaws suddenly become —*e.g.*, in *Nothosaurus mirabilis* (fig. 70)—very small, and form a straight, numerous, and close-set single series along the maxillary and corresponding part of the mandibular bone.

Both *Nothosaurus* and *Pistosaurus* had many neck-vertebræ; and the transition from these to the dorsal series was effected, as in *Plesiosaurus*, by the ascent of the rib-surface from the centrum to the neurapophysis; but the surface, when divided between the two elements, projected further outwards than in most *Plesiosauri*.

In both *Notho-* and *Pisto-saurus* the pelvic vertebra develops a combined process (par- and di-apophysis), but of relatively larger, vertically longer size, standing well out, and from near the fore part of the side of the vertebra. This process, with the coalesced riblet, indicates a stronger ilium, and a firmer base of attachment of the hind limb to the trunk, than in *Plesiosaurus*. Both this structure, and the greater length of the bones of the fore arm and leg show that the muschelkalk predecessors of the liassic *Plesiosauri* were better organized for occasional progression on dry land. More than twenty species of *Plesiosaurus* have been described by, or are known to, the writer: their remains occur in the oolitic, Wealden, and cretaceous formations, ranging from the lias upwards to the chalk, inclusive. A comparison of remains of various *Plesiosauri* has led to a conviction, that specific distinctions are accompanied with well-marked differences in the structure and proportions of answerable vertebræ, but are not shown in small differences of number in the cervical, dorsal, or caudal vertebræ.

Reptilia.

When any region of the vertebral column presents an unusual excess of development in a genus, such region is more liable to variation, within certain limits, than in genera where its proportions are more normal. The differences of the number of cervical and dorsal vertebræ, ranging between 29 and 31 in the *Plesiosaurus Hawkinsii*, *e g.*,—as noted in the description of that species in the writer's *Report on British Fossil Reptiles*, 1839,—indicate the range of variety observed in the only species of which, at that time, the vertebral column of different individuals could be compared.

Genus PLIOSAURUS, Ow.—M. von Meyer regards the number of cervical vertebræ and the length of neck as characters of prime importance in the classification of *Reptilia*, and founds thereon his order called *Macrotrachelen*, in which he includes *Simosaurus*, *Pistosaurus*, and *Nothosaurus*, with *Plesiosaurus*. No doubt the number of vertebræ in the same skeleton bears a certain relation to ordinal groups: the *Ophidia* find a common character therein; yet it is not their essential character, for the snake-like form, dependent on multiplied vertebræ, characterizes equally certain Batrachians (*Cœcilia*) and fishes (*Murœna*). Certain regions of the vertebral column are the seats of great varieties in the same natural group of *Reptilia*. We have long-tailed and short-tailed lizards; but do not therefore separate those with numerous caudal vertebræ, as "Macroura," from those with few or more. The extinct *Dolichsaurus* of the Kentish chalk, with its procœlian vertebræ, cannot be ordinarily separated, by reason of its more numerous cervical vertebræ, from other shorter-necked procœlian lizards. As little can we separate the short-necked and big-headed amphicœlian Pliosaur from the Macrotrachelians with which it has its most intimate and true affinities.

There is much reason, indeed, to suspect that some of the muschelkalk Saurians, which are as closely allied to *Nothosaurus* as *Pliosaurus* is to *Plesiosaurus*, may have presented analogous modifications in the number and proportions of the cervical vertebræ. It is hardly possible to contemplate the broad and short-snouted skull of the *Simosaurus*, with its proportionally large teeth, without inferring that such a head must have been supported by a shorter and more powerful neck than that which bore the long and slender head of the *Nothosaurus* or *Pistosaurus*. The like inference is more strongly impressed upon the mind by the skull of the *Placodus*, still shorter and broader than that of *Simosaurus*, and with vastly larger teeth, of a shape indicative of their adaptation to crushing molluscous or crustaceous shells.

Neither the proportions and armature of the skull of *Placodus*, nor the mode of obtaining the food indicated by its cranial and dental characters, permit the supposition that the head was supported by other than a comparatively short and strong neck. Yet the composition of the skull, its proportions, cavities, and other light-giving anatomical characters, all bespeak the close essential relationship of *Placodus* to *Simosaurus* and other so-called "macrotrachelian" reptiles of the muschelkalk beds. The writer continues, therefore, to regard the fin-like modification of the limbs as a better ordinal character than the number of vertebræ in any particular region of the spine. But whilst retaining the term *Enaliosauria* for the large extinct natatory group of saurian reptiles, the essential distinctness of the groups *Sauropterygii* and *Ichyopterygii*, typified by the *Ichthyosaurus* and *Plesiosaurus* respectively, should be borne in mind.

Sp. *Pliosaurus brachydeirus*, Ow.—The generic characters of *Pliosaurus* are given by the teeth and the cervical vertebræ. As compared with those of *Plesiosaurus*, the teeth are thicker in proportion to their length, are subtrihedral in transverse section, with one side flattened, and bounded by lateral prominent ridges from

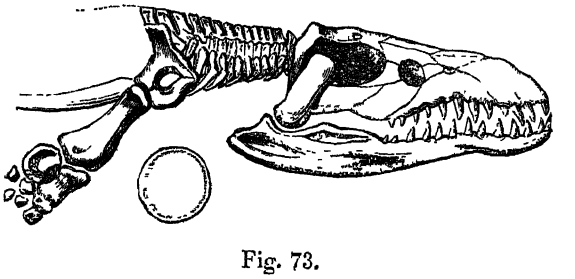

Fig. 73.
Pliosaurus (Kimmeridgian).

the more convex sides, which are rounded off into each other, and alone show the longitudinal ridges of the enamel; these are there very well defined. The vertebræ of the neck, presenting a flat

[1] Von Meyer, *Muschelkalk Saurier*.

articular surface of the shape shown in outline below the neck in fig. 73, are so compressed from before backward as to resemble the vertebræ of the *Ichthyosaurus*, and as many as twelve may be compressed within the short neck intervening between the skull and scapular arch, as shown in fig. 73. For the rest, save in the more massive proportions of the jaws and paddle-bones, the bony framework of *Pliosaurus* closely accords with that of *Plesiosaurus;* and, as the vertebræ of the trunk resume the plesiosaurian proportions, they give little indication of the genus of reptile to which they truly belong, when found detached and apart. Some individuals of *Pliosaurus* appear to have attained a bulk of between 30 and 40 feet. The remains of this modified form of Enaliosaur are peculiar to the Oxfordian and Kimmeridgian divisions of the upper oolitic system. They have been discovered in these beds in Russia (*Pliosaurus Worinskii* and *Spondylosaurus* of Fischer), as well as in those counties of England where the Kimmeridge and Oxford clays have been deposited.

Sub-order 2.—ICHTHYOPTERYGIA.

Genus ICHTHYOSAURUS.—The name (from the Greek *ichthys*, a fish, and *sauros*, a lizard) was devised to indicate the closer affinity of the Ichthyosaur, as compared with the Plesiosaur, to the class of fishes. The Ichthyosaur (fig. 74) is remarkable for the shortness

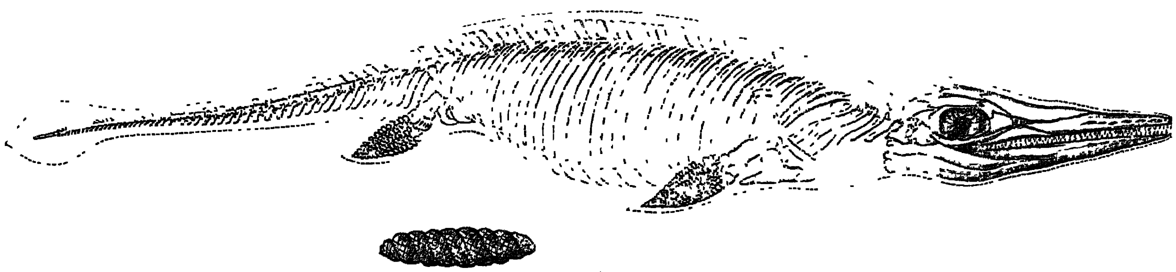

Fig. 74.

Ichthyosaurus (Lias).

of the neck and the equality of the width of the back of the head with the front of the chest, impressing the observer of the fossil skeleton with a conviction that the ancient animal must have resembled the whale tribe and the fishes, in the absence of any intervening constriction or "neck."

This close approximation in the Ichthyosaurs to the form of the most strictly aquatic vertebrate animals of the existing creation, is accompanied by an important modification of the surfaces forming the joints of the back-bone, each of which surfaces are hollow, leading to the inference that they were originally connected together by an elastic bag or "capsule" filled with fluid,—a structure which prevails in the class of fishes, in the Labyrinthodonts and a few extinct aquatic reptiles, in the existing perennibranchiate Batrachia, but not in any of the whale or porpoise tribe.

With the above modifications of the head, trunk, and limbs, in relation to swimming, there co-exist corresponding modifications of the tail. The bones of this part are much more numerous than in the Plesiosaurs, and the entire tail is consequently longer; but it does not show any of those modifications that characterize the bony support of the tail in fishes. The numerous "caudal vertebræ" of the *Ichthyosaurus* gradually decrease in size to the end of the tail, where they assume a compressed form, or are flattened from side to side, and thus the tail, instead of being short and broad as in fishes, is lengthened out as in crocodiles.

The very frequent occurrence of a fracture of the tail, about one-fourth of the way from its extremity, in well preserved and entire fossil skeletons, is owing to that proportion of the end of the tail having supported a tail fin. The only evidence which the fossil skeleton of a whale would yield of the powerful horizontal tail-fin characteristic of the living animal, is the depressed or horizontally-flattened form of the bones supporting such fin. It is inferred, therefore, from the corresponding bones of the *Ichthyosaurus* being flattened in the vertical direction, or from side to side, that it possessed a tegumentary tail fin expanded in the vertical direction. The shape of a fin composed of such perishable material is of course conjectural, as is the outline in fig. 74. Thus, in the construction of the principal swimming organ of the *Ichthyosaurus* we may trace, as in other parts of its structure, a combination of mammalian (beast-like), saurian (lizard-like), and piscine (fish-like) peculiarities. In the great length and gradual diminution of the tail we perceive its saurian character; in the tegumentary nature of the fin, unsustained by bony fin-rays, its affinity to the same part in the mammalian whales and porpoises is shown; whilst its vertical position makes it closely resemble the tail fin of the fish.

The horizontality of the tail fin of the whale tribe is essentially connected with their necessities as warm-blooded animals breathing atmospheric air; without this means of displacing a mass of water in the vertical direction, the head of the whale could not be brought with the required rapidity to the surface to respire; but the Ichthyosaurs, not being warm-blooded or quick breathers, would not need to bring their head to the surface so frequently or so rapidly as the whale; and moreover a compensation for the want of horizontality of their tail fin was provided by the addition of a pair of hind paddles, which are not present in the whale tribe. The vertical fin was a more efficient organ in the rapid cleaving of the liquid element, when the Ichthyosaurs were in pursuit of their prey or escaping from an enemy.

The general form of the cranium of the *Ichthyosaurus* resembles that of the ordinary cetaceous dolphin (*Delphinus tursio*); but the *I. tenuirostris* rivals the *Delphinus gangeticus* in the length and slenderness of the jaws. The essential difference in the sea-reptile lies in the restricted size of the cerebral cavity, and the vast depth and breadth of the zygomatic arches, to which the seeming expanse of the cranium is due; still more in the persistent individuality of the elements of those cranial bones which have been blended into single though compound bones in the sea-mammal. The *Ichthyosaurus* further differs in the great size of the premaxillary and small size of the maxillary bones, in the lateral aspects of the nostrils, in the immense size of the orbits, and in the large and numerous sclerotic plates, which latter structures give to the skull of the *Ichthyosaurus* its most striking features.

The true affinities of the Ichthyosaur are, however, to be elucidated by a deeper and more detailed comparison of the structure of the skull; and few collections now afford richer materials for pursuing and illustrating such comparisons than the palæontological series in the British Museum[1] The two supplemental bones of the skull, which have no homologues in existing Crocodilians, are the post-orbital and super-squamosal; both, however, are developed in *Archegosaurus* and the Labyrinthodonts. The post-orbital is the homologue of the inferior division of the post-frontal in those Lacertians—*e g., Iguana, Tejus, Ophisaurus, Anguis*, in which that bone is said to be divided. But in *Ichthyosaurus* the post-orbital resembles most a dismemberment of the malar. Its thin obtuse scale-like lower end overlaps and joins by a squamous suture the hind end of the malar: the post-orbital expands as it ascends to the middle of the back of the orbit, then gradually contracts to a point as it curves upward and forward, articulating with the super-squamosal and post-frontal. The super-squamosal may be in like manner regarded as a dismemberment of the squamosal; were it confluent therewith, the resemblance which the bone would present to the zygomatic and squamosal parts of the mammalian temporal would be very close; only the squamosal part would be removed from the inner wall to the outer wall of the temporal fossa. The super-squamosal, in fact, occupies the position of the temporal fascia in *Mammalia*, and should be regarded as a supplemental sclero-dermal plate, closing the vacuity between the upper and lower elements of the zygomatic arch, peculiar to certain air-breathing *Ovipara*. It is a broad, thin, flat, irregular-shaped plate, smooth and slightly convex externally, and wedged into the interspaces between the post-frontal, post-orbital, squamosal, tympanic, and mastoid.

The principal vacuities or apertures in the bony walls of the skull of the *Ichthyosaurus* are the following:—In the posterior region the "foramen magnum," the occipito-parietal vacuities, and

[1] The anatomical reader is referred to the writer's "Report on British Fossil Reptiles," *Trans. Brit. Assoc.* 1839, and to the *Annals and Magazine of Natural History*, 1858, p. 388.

Reptilia.

the auditory passages; on the upper surface the parietal foramen and the temporal fossæ; on the lateral surfaces the orbits and nostrils, the plane of the aperture in both being vertical; on the inferior surface the palato-nasal, the pterygo-sphenoid, and the pterygo-malar vacuities. The occipito-parietal vacuities are larger than in *Crocodilia*, smaller than in *Lacertilia*, they are bounded internally by the basi-, ex-, and super-occipitals, externally by the parietal and mastoid. The auditory apertures are bounded by the tympanic and squamosal. The tympanic takes a greater share in the formation of the "meatus auditorius" in many lizards; in crocodiles it is restricted to that which it takes in *Ichthyosaurus*.

The orbit is most remarkable in the *Ichthyosaurus*, amongst reptiles, both for its large proportional size and its posterior position; in the former character it resembles that in the lizards, in the latter that in the crocodiles. It is formed by the pre- and post-frontals above, by the lacrymal in front, by the post-orbital behind, and by the peculiar long and slender malar bar below. In crocodiles and in most lizards the frontal enters into the formation of the orbits, and in lizards the maxillary also. The nostril is a longish triangular aperture, with the narrow base behind; it is bounded by the lacrymal, nasal, maxillary, and pre-maxillary. It is proportionally larger than in the *Plesiosaurus*, and is distant from the orbit about half its own long diameter. Like the orbit, the plane of its outlet is vertical.

The pterygo-palatine vacuities are very long and narrow, broadest behind, where they are bounded, as in lizards, by the anterior concavities of the basi-sphenoid, and gradually narrowing to a point close to the palatine nostrils. These are smaller than in most lizards, and are circumscribed by the palatines, ecto-pterygoid, maxillary, and pre-maxillary. The pterygo-malar fissures are the lower outlets of the temporal fossæ; their sudden posterior breadth, due to the emargination of the pterygoid, relates to the passage of the muscles for attachment to the lower jaw. The parietal foramen is bounded by both parietals and frontals; its presence is a mark of labyrinthodont and lacertian affinities, its formation is like that in *Iguana* and *Rhynchocephalus* The temporal fossæ are bounded above by the parietal internally, by the mastoid and post-frontal externally; they are of an oval form, with the great end forward. In their relative size and backward position they are more crocodilian than lacertian.

In the *Ichthyosaurus communis* there are seventeen sclerotic plates forming the fore part of the eyeball. In a well-preserved example, the pupillary or corneal vacuity, as bounded by those plates, is of a full oval form, 1½ inch in long diameter, the length of the plates (or breadth of the frame) being from 8 to 10 lines. In the same skull the long diameter of the orbit is 4 inches. The deep position of the sclerotic circle in this cavity showed how they had sunk, by pressure of the external mud, as the eyeball became collapsed by escape of the humours in decomposition.

Whenever the antecedent forms an extinct genus of any class are known, the characters of such genus should be compared with those of its predecessors rather than with its successors or with existing forms, in order to gain an insight into its true affinities.

We derive a truer conception of the affinities of the *Ichthyosaurus* by comparison with the Labyrinthodonts and other triassic reptiles, as we do of the *Plesiosaurus* by comparison with the muschelkalk *Sauropterygia*, than of either by comparison with modern Lacertians and Crocodilians. It is commonly said that the *Ichthyo-* or the *Plesiosaurus* resembles more the lizards in such and such characters, and in a less degree the crocodiles, as in such a character. The truer expression would be that the lizards, which are the predominating form of Saurians at the present day, have retained more of the osteological type of the triassic and oolitic reptiles, and that the crocodiles deviate further from them or exhibit a more modified or specialized structure. The posterior position of the nostrils, the small size and position of the palato-pterygoid foramen, are marks of affinity to *Plesiosaurus*, in common with which genus the cranial structure of the *Ichthyosaurus* exhibits a majority of lacertian characters.

In comparing the jaws of the *Ichthyosaurus termirostris* with those of the gangetic Gharrial an equal degree of strength and of alveolar border for teeth result from two very different proportions in which the maxillary and premaxillary bones are combined together to form the upper jaw. The prolongation of the snout has evidently no relation to this difference; and we are accordingly led to look for some other explanation of the disproportionate development of the premaxillaries in the *Ichthyosaurus*. It appears to me to give additional proof of the collective tendency of the affinities of the *Ichthyosaurus* to the lacertian type of structure. The backward or antorbital position of the nostrils, like that in whales, is related to their marine existence. But in the Lacertians in which the nostrils extend to the fore part of the head, their anterior boundaries are formed by the premaxillaries: it appears, therefore, to be in conformity with the lacertian affinities of the Ichthyosaur that the premaxillaries should still enter in the same relation with the nostrils, although this involves an extent of anterior development proportionate to the length of the jaws, the forward production of which sharp-toothed instruments fitted them, as in the modern dolphins, for the prehension of agile fishes.

Reptilia.

That the Ichthyosaurs occasionally sought the shores, crawled on the strand, and basked in the sunshine, may be inferred from the bony structure connected with their fore fins, which does not exist in any porpoise, dolphin, grampus, and whale; and for want of which, chiefly, those warm-blooded, air-breathing, marine animals are so helpless when left high and dry on the sands. The structure in question in the Ichthyosaur is a strong osseous arch, inverted and spanning across beneath the chest from one shoulder-joint to the other; and what is most remarkable in the structure of this "scapular" arch is, that it closely resembles, in the number, shape, and disposition of its bones, the same part in the singular aquatic mammalian quadruped of Australia, called *Ornithorynchus*, and *Platypus*, or duck-mole. The Ichthyosaur, when so visiting the shore either for sleep or procreation, would lie or crawl prostrate, or with its belly resting or dragging on the ground.

The most extraordinary feature of the head was the enormous magnitude of the eye: and from the quantity of light admitted by the expanded pupil, it must have possessed great powers of vision, especially in the dusk. It is not uncommon to find in front of the orbit in fossil skulls, a circular series of petrified thin bony plates, ranged round a central aperture, where the pupil of the eye was placed. The eyes of many fishes are defended by a bony covering consisting of two pieces; but a compound circle of overlapping plates is now found only in the eyes of turtles, tortoises, lizards, and birds. This curious apparatus of bony plates would aid in protecting the eye-ball from the waves of the sea when the *Ichthyosaurus* rose to the surface, and from the pressure of the dense element when it dived to great depths; and they show, writes Dr Buckland (*Bridgewater Treatise*) "that the enormous eye of which they formed the front, was an optical instrument of varied and prodigious power, enabling the *Ichthyosaurus* to descry its prey at great or little distances, in the obscurity of night, and in the depths of the sea."

Of no extinct species are the materials for a complete and exact restoration more abundant and satisfactory than of the *Ichthyosaurus*; they plainly show that its general external figure must have been that of a huge predatory abdominal fish, with a longer tail and a smaller tail-fin, scaleless, moreover, and covered by a smooth or finely wrinkled skin, analogous to that of the whale tribe.

The mouth was wide, and the jaws long, and armed with numerous pointed teeth, indicative of a predatory and carnivorous nature in all the species; but these differed from one another in regard to the relative strength of the jaws, and the relative size and length of the teeth.

Masses of masticated bones and scales of extinct fishes that lived in the same seas and at the same period as the *Ichthyosaurus*, have been found under the ribs of fossil specimens, in the situation where the stomach of the animal was placed; smaller, harder, and more digested masses, containing also fish-bones and scales have been found, bearing the impression of the structure of the internal surface of the intestine of the great predatory sea-lizard. One of these "Coprolites" is figured beneath the skeleton in fig. 74.

In tracing the evidences of creative power from the earlier to the later formations of the earth's crust, remains of the *Ichthyosaurus* are first found in the lower lias, and occur more or less abundantly through all the superincumbent secondary strata up to, and inclusive of, the chalk formations. They are most numerous in the lias and oolite, and the largest and most characteristic species have been found in these formations.

More than thirty species of *Ichthyosaurus* are known to the writer, many of which have been described or defined.

ORDER V.—DINOSAURIA.

Char.—Cervical and anterior dorsal vertebræ, with par- and di-apophyses, articulating with bifurcate ribs; dorsal vertebræ, with a neural platform, sacral vertebræ exceeding two in number; body supported on four strong unguiculate limbs.

The well-ossified vertebræ, large and hollow limb-bones, and tritrochanterian femora of the thecodont reptiles of the Bristol conglomerate, together with the structure of the sacral vertebræ in the allied *Belodon*, indicate the beginning, at the triassic period, of an order of *Reptilia* which acquired its full development and typical characteristics in the oolitic period.

Genus SCELIDOSAURUS, Ow.—By this name is indicated a Saurian with large and hollow limb-bones, with a femur having the third inner trochanter, and with metacarpal and phalangial bones,

adapted for movement on land. The fossils occur in the lias at Charmouth, Dorsetshire.

Genus MEGALOSAURUS, Bkld.—The true dinosaurian characters of this reptile have been established by the discovery of the sacrum, which consists of five vertebræ, interlocked by the alternating position of neural arch and centrum. The articular surfaces of the free vertebræ are nearly flat; the neural arch develops a platform which in the anterior dorsals supports very long and strong spines. The dental characters are described and figured in the article ODONTOLOGY, vol. xvi., p. 433, fig. 48.

The oldest known beds from which any remains of *Megalosaurus* have been obtained are the lower oolites at Selsby Hill, and Chipping-Norton, Gloucestershire. Abundant and characteristic remains occur in the Stonesfield slate, Oxfordshire. Teeth of the *Megalosaurus* have been found in the Cornbrash and Bath oolite; both teeth and bones are common in the Wealden strata and Purbeck limestone. Some of these fossils indicate a reptile of at least 30 feet in length.

Genus HYLÆOSAURUS, Mtll.—Remains of the Dinosaurian so called have hitherto been found only in Wealden strata, as at Tilgate, Bolney, and Battle. The most instructive evidence is that which was exposed by the quarrymen of the Wealden stone at Tilgate, and obtained and described by Mantell in 1832. It consisted of a block of stone measuring 4½ feet by 2½ feet (fig. 75), and included the following parts of the skeleton in almost

Fig. 75.

Hylæosaurus (Wealden).

natural juxtaposition:—10, Anterior vertebræ, the first supporting part of the base of the skull; several ribs, 4, 4; some enormous dermal bony spines, 5, 6, 6, which supported a strong defensive crest along the back; two coracoids, 7, 7; scapulæ, 8, 8; and some detached vertebræ and fragments of bones. The sacrum was dinosaurian, and included five vertebræ.

The teeth were relatively small, close-set, thecodont in implantation, with subcylindrical fang and a subcompressed slightly expanded and incurved crown, with the borders straight, and converging to the blunt apex. They indicate rather a mixed or vegetable diet than a carnivorous one. The skin was defended by subcircular bony scales. The length of the Hylæosaur may have been 25 feet.

Genus IGUANODON, Mtll.—Remains of these large herbivorous reptiles have been found in Wealden and neocomian (greensand) strata. Femora, 4 feet in length, showing the third inner trochanter, have been discovered. The sacrum included five, and in old animals six vertebræ; the claw-bones are broad, flat, and obtuse. There were only three well-developed toes on the hind foot, and singular large tridactyle impressions, discovered by Beccles in the Wealden at Hastings have been conjectured to have been made by the Iguanodon. The characteristic dentition of this genus is described in the article ODONTOLOGY, p. 435, figs. 42, 43, and 44. All trace of dinosaurian reptiles disappears in the lower cretaceous beds.

ORDER VI.—PTEROSAURIA.

The species of this order of reptiles are extinct, and peculiar to the mezozoic period. Their chief characteristic is the development of the pectoral limbs into organs of flight (fig. 76). This is due to an elongation of the antibrachial bones, and more especially to the still greater length of the metacarpal and phalangial bones of the fifth or innermost digit (fig. 76, 5), the last phalanx of which terminates in a point. The other fingers were of more ordinary length and size, and terminated by claws. The number of phalanges is progressive from the first (fig. 76, 1) to the fourth (4), which is a reptilian character. The whole osseous system is modified in accordance with the possession of wings; the bones are light, hollow, most of them permeated by air-cells, with thin compact outer walls. The scapula and coracoid are long and narrow, but strong. The vertebræ of the neck are few, but large and strong, for the support of a large head with long jaws, armed with sharp-pointed teeth. The skull was lightened by large vacuities, of which one (*o*, fig. 76) is interposed between the nostril *n* and the orbit *l*. The

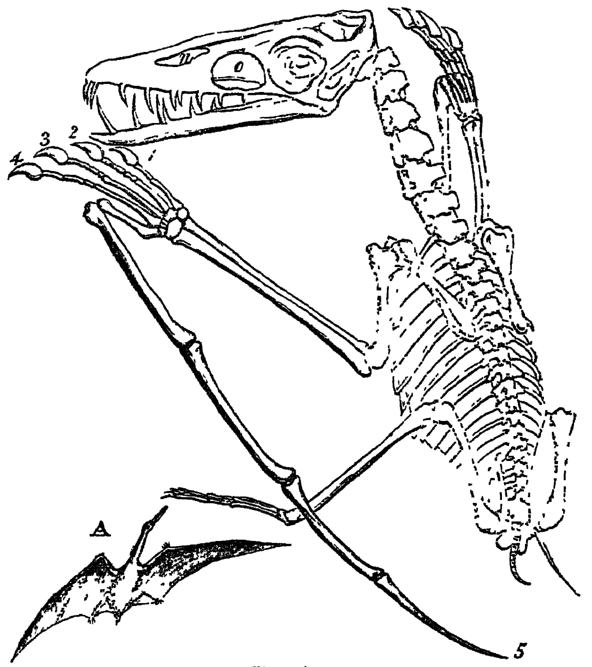

Fig. 76.

Fossil Skeleton of *Pterodactylus crassirostris*: A, Sketch of Living Pterodactyle.

vertebræ of the back are small, and grow less to the tail. Those of the sacrum are few and small, and the pelvis and weak hind limbs bespeak a creature unable to stand and walk like a bird. The body must have been dragged along the ground like that of a bat. But the *Pterosauria* may have been good swimmers as well as flyers. The vertebral bodies unite by ball-and-socket joints, the cup being anterior, and in them we have the earliest manifestation of the "procœlian" type of vertebra. The atlas consists of a discoid centrum, and of two slender neuropophyses; the centrum of the axis is ten times longer than that of the atlas, with which it ultimately coalesces; it sends off from its under and back part a pair of processes, above which is transversely extended convexity articulating with the third cervical vertebra. In each vertebra there is a large pneumatic foramen at the middle of the side. The neural arch is confluent with the centrum. Dentition thecodont.

Genus DIMORPHODON, Ow.

Sp. *Dimorphodon macronyx*, Bkd.—The Pterodactyles are distributed into sub-genera, according to well-marked modifications of the jaws and teeth. In the oldest known species, from the lias, the teeth are of two kinds; a few at the fore part of the jaws are long, large, sharp-pointed, with a full elliptical base; behind them is a close-set row of short, compressed, very small lancet-shaped teeth. In a specimen of *Dimorphodon macronyx*, from the lower lias of Lyme Regis, the skull was 8 inches long, and the expanse of wing about 4 feet. There is no evidence of this species having had a long tail.

Genus RAMPHORHYNCHUS, Von Meyer.—In this genus the fore part of each jaw is without teeth, and may have been encased by a horny beak, but behind the edentulous production there are four or five large and long teeth, followed by several smaller ones. The tail is long, stiff, and slender.

The *Ramphorhynchus longicaudus*, *R. Gemmingi*, and *R. Münsteri* belong to this genus. All are from the lithographic (middle oolitic) slates of Bavaria.

Genus PTERODACTYLUS, Cuv.—The jaws are provided with teeth to their extremities; all the teeth are long, slender, sharp-pointed, set well apart. The tail is very short.

P. longirostris, Ok.—About 10 inches in length; from lithographic slate at Pappenheim. *P. crassirostris*, Goldf.—About 1 foot long; same locality (fig. 76.) *P. Kochii*, Wagn.—8 inches long; from the lithographic slates of Kehlheim. *P. medius*, Mnst.—10 inches long; from the lithographic slates at Meulenhard. *P.*

Reptilia.

grandis, Cuv.—14 inches long; from lithographic slates of Solenhofen. Two small and probably immature Pterodactyles, showing the short jaws characteristic of such immaturity, have been entered as species under the names of *P. brevirostris* and *P. Meyeri*. The latter shows the circle of sclerotic eye-plates.

The fragmentary remains of Pterodactyle from British oolite,—e g, Stonesfield slate, usually entered as *Pterodactylus Bucklandi*,—indicate a species about the size of a raven.

The evidences of Pterodactyles from the Wealden strata indicate species about 16 inches in length of body. Those (*P. Fittoni*, and *P. Sedgwickii*, Ow) from the greensand formation, near Cambridge, with neck-vertebræ 2 inches long, and humeri measuring 3 inches across the proximal joint, had a probable expanse of wing of from 18 to 20 feet. The *P. Cuvieri*, Ow., and *P. compressirostris*, Ow., from the chalk of Kent, attained dimensions very little inferior to those of the greensand Pterodactyles

More evidence is yet needed for the establishment of the pterosaurian genus, on the alleged character of but two phalanges in the wing-finger, and for which the term "Ornithopterus" has been proposed by Von Meyer.

With regard to the range of this remarkable order of flying reptiles in geological time, the oldest well-known Pterodactyle is the *Dimorphodon macronyx*, of the lower lias; but bones of Pterodactyle have been discovered in the coeval lias of Wirtemberg. The next in point of age is the *Ramphorhynchus Banthensis*, from the "Posidonomyen-schiefer" of Banz in Bavaria, answering to the alum shale of the Whitby lias; then follows the *P. Bucklandi* from the Stonesfield oolite. Above this come the first-defined and numerous species of Pterodactyle from the lithographic slates of the middle oolitic system in Germany, and from Cirin, on the Rhone. The Pterodactyles of the Wealden are as yet known to us by only a few bones and bone fragments. The largest known species are those from the greensand of Cambridgeshire. Finally, the Pterodactyles of the middle chalk of Kent, almost as remarkable for their great size, constitute the last forms of flying reptile known in the history of the crust of this earth.

ORDER VII.—CROCODILIA.

Char.—Teeth in a single row, implanted in distinct sockets, external nostril single and terminal or sub-terminal. Anterior trunk vertebræ with par- and di-apophyses, and bifurcate ribs; sacral vertebræ two, each supporting its own neural arch. Skin protected by bony, usually pitted plates.

Sub-order 1.—AMPHICŒLA.[1]

Crocodiles closely resembling in general form the long and slender-jawed kind of the Ganges called Gavial, existed from the time of the deposition of the lower lias.

Their teeth were similarly long, slender, and sharp, adapted for the prehension of fishes, and their skeleton was modified for more efficient progress in water by the vertebral surfaces being slightly concave, by the hind limbs being relatively larger and stronger, and by the orbits forming no prominent obstruction to progress through water. From the nature of the deposits containing the remains of the so-modified crocodiles, they were marine. The fossil crocodile from the Whitby lias, described and figured in the *Philosophical Transactions*, 1758, p. 688, is the type of these amphicœlian species. They have been grouped under the following generic heads:—*Teleosaurus, Steneosaurus, Mystriosaurus, Macrospondylus, Massospondylus*, to which must be added *Pœcilopleuron, Pelagosaurus, Æolodon, Suchosaurus, Goniopholis, Polyptychodon*.

Species of the above genera range from the lias to the chalk inclusive.

Suchosaurus of the Wealden is characterized by the compressed crown and trenchant margins of the teeth; *Goniopholis*, of the Purbeck beds, by some of the dermal scales having the same peg-and-pit interlocking as in the scales of the ganoid fish in fig. 52; *Polyptychodon* of the greensand and chalk, by the well-defined numerous longitudinal ridges of the enamel; from the size of some of these teeth, this crocodile, like the Pterodactyles of the same period, appears to have been the largest of its group; it surpassed all other Amphicœlians in size.

Sub-order 2.—OPISTHOCŒLIA.[2]

The small group of Crocodilia so called is an artificial one, based upon more or less of the anterior trunk vertebræ being united by ball-and-socket joints, but having the ball in front, instead of, as in modern crocodiles, behind Cuvier first pointed out this peculiarity[3] in a Crocodilian from the Oxfordian beds at Honfleur, and the Kimmeridgian at Havre. The writer has described similar opisthocœlian vertebræ from the great oolite at Chipping Norton, from the upper lias of Whitby, and, but of much larger size, from the Wealden formations of Sussex and the Isle of Wight. These specimens probably belong, as suggested by the writer in 1841,[4] to the fore part of the same vertebral column as the vertebræ, flat at the fore part, and slightly hollow behind, on which he founded the genus *Cetiosaurus*. The smaller opisthocœlian vertebræ described by Cuvier have been referred by Von Meyer to a genus called *Streptospondylus*.

In one species from the Wealden, dorsal vertebræ measuring 8 inches across are only 4 inches in length, and caudal vertebræ nearly 7 inches across are less than 4 inches in length. These characterize the species called *Cetiosaurus brevis*.[5]

Caudal vertebræ measuring 7 inches across and 5½ inches in length, from the lower oolite at Chipping Norton, and the great oolite at Enstone, represent the species called *Cetiosaurus medius*.

Caudal vertebræ from the Portland stone at Garsington, Oxfordshire, measuring 7 inches 9 lines across and 7 inches in length, are referred to the *Cetiosaurus longus*. The latter must have been the most gigantic whale-like of Crocodilians, unless it were equalled in bulk by the *Polyptychodon* of the chalk.

Sub-order 3.—PROCŒLIA.[6]

Crocodilians with cup-and-ball vertebræ, like those of living species, first make their appearance in the greensand of North America (*Crocodilus basifissus* and *C. basitruncatus*). In Europe their remains are first found in the tertiary strata. Such remains from the plastic clay of Meudon have been referred to *C. isorhynchus, C. cœlorhynchus, C. Becquereli*. In the calcaire grossier of Argenton and Castelnaudry have been found the *C. Rallinati* and *C. Dodunii*. In the coeval eocene London clay at Sheppy Island the entire skull and characteristic parts of the skeleton of *C. toliapicus* and *C Champsoides* occur. In the somewhat later eocene beds at Bracklesham occur the remains of the gavial-like *C. Dixoni* In the Hordle beds have been found the *C. Hastingsiæ*, with short and broad jaws; and also a true alligator (*C. Hantoniensis*). It is remarkable that forms of procœlian Crocodilia, now geographically restricted—the gavial to Asia, and the alligator to America—should have been associated with true crocodiles, and represented by species which lived, during nearly the same geological period, in rivers flowing over what now forms the south coast of England.

Many species of procœlian Crocodilia have been founded on fossils from miocene and pliocene tertiaries. One of these, of the gavial sub-genus (*C. crassidens*), from the Sewalik tertiary, was of gigantic dimensions.

ORDER VIII.—LACERTILIA.

Char.—Vertebræ procœlian, with a single transverse process on each side, and with single-headed ribs; sacral vertebræ not exceeding two.

Small vertebræ of this type have been found in the Wealden of Sussex. They are more abundant, and are associated with other generic characteristic parts of the species, in the cretaceous strata. On such evidence have been based the *Raphiosaurus subulidens*, the *Coniasaurus crassidens*, and the *Dolichosaurus longicollis*. The last-named species is remarkable for the length and slenderness of its trunk and neck, indicative of a tendency to the ophidian form. But the most remarkable and extreme modification of the lacertian type in the cretaceous period is that manifested by the huge species, of which a cranium 5 feet long was discovered in the upper chalk of St Peter's Mount, near Maestricht, in 1780. The vertebræ are gently concave in front, and convex behind; there are thirty-four between the head and the base of the tail: a sacrum seems to have been wanting. The caudal vertebræ have long neural and hæmal spines, both of which arches coalesce with the centrum, and formed the basis of a powerful swimming tail. The teeth are anchylosed to eminences along the alveolar border of the jaw, according to the acrodont type. There is a row of small teeth on each pterygoid bone. For this genus of huge marine lizard the name *Mosasaurus* has been proposed. Besides the *M Hofmanni* of Maestricht, there

[1] *Amphi*, both, *koilos*, hollow; the vertebra being hollowed at both ends.

[2] *Opisthos*, behind, *koilos*, hollow; vertebra concave behind, convex in front.

[4] "Report on British Fossil Reptiles," *Trans. Brit. Assoc.* for 1841, p. 96.

[5] They have since been referred to the dinosaurian order under the name of *Pelorosaurus*, but without any evidence of the true sacral characters of that order; the cavities of long bones are common to Crocodilians and Dinosaurs.

[6] *Pros*, front, *koilos*, hollow; vertebra with the cup at the fore part and the ball behind.

Reptilia.

is a *M. Maximiliani*, from the cretaceous beds of North America, and a smaller species, *M. gracilis*, from the chalk of Sussex The *Leiodon anceps* of the Norfolk chalk was a nearly allied marine Lacertian. Many small terrestrial Lacertians have left their remains in European tertiary formations.

ORDER IX.—OPHIDIA.

(*Serpents.*)

The earliest evidence of an ophidian reptile has been obtained from the eocene clay at Sheppy: it consists of vertebræ indicating a serpent of 12 feet in length, the *Palæophis toliapicus*. Still larger, more numerous, and better preserved vertebræ have been obtained from the eocene beds at Bracklesham, on which the *Palæophis typhœus* and *P. porcatus* have been founded. These remains indicate a boa-constrictor-like snake, of about 20 feet in length. Ophidian vertebræ of much smaller size, from the newer eocene at Hordwell, support the species called *Paleryx rhombifer* and *P depressus.* Fossil vertebræ from a tertiary formation near Salonica have been referred to a serpent, probably poisonous, under the name of *Laophis*. A species of true viper has been discovered in the miocene deposits at Sansans, South of France. Three fossil Ophidians from the Œningen slate have been referred to *Coluber arenatus, C. Kargii*, and *C. Owenii*.

ORDER X.—CHELONIA.

(*Tortoises and Turtles.*)

Reference has already been made to the impressions in sandstones of triassic age in Dumfriesshire, referred by Dr Duncan to tortoises. These impressions have been finely illustrated in the great work by Sir William Jardine on the foot-prints at Corncockle Muir. The earliest proof of chelonian life which the writer has obtained has been afforded by the skull of the *Chelone planiceps*, from the Portland stone; and by the carapace and plastron of the extinct and singularly-modified emydian genera *Tretosternon* and *Pleurosternon*[1] (fig. 77). In the first genus the plastron retains the central vacuity; in the second genus an additional pair of bones is interposed between the hyosternals (*hs*) and hyposternals (*ps*). In the specimen figured (fig. 77), the plastron, and the under surface

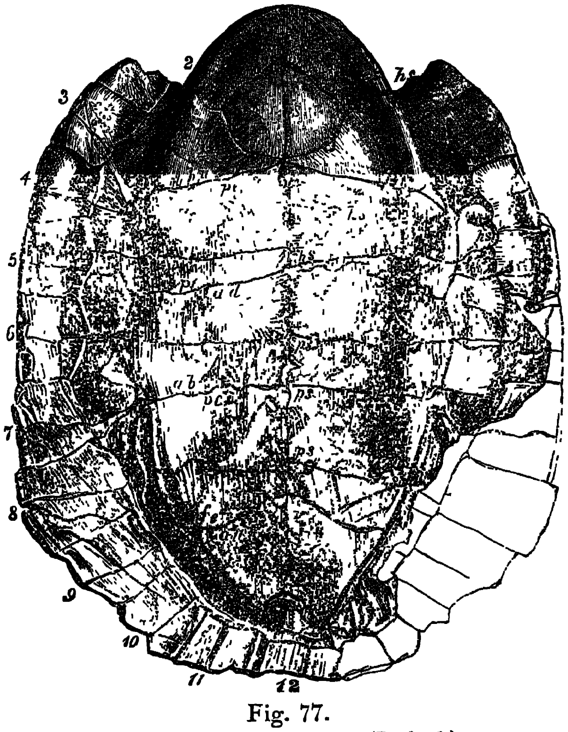

Fig. 77.

Pleurosternon emarginatum (Purbeck).

of the marginal pieces (2 to 12) of the carapace, of *Pleurosternon emarginatum* are shown. This fine Chelonite is now in the British Museum.

True marine turtles (*Chelone Camperi, C. obovata, C. pulchriceps*) have left their remains in cretaceous beds. The emydian *Protemys* is from the greensand near Maidstone. The eocene tertiary deposits of Britain yield rich evidences of marine, estuary, and fresh-water tortoises. More species of true turtle have left their remains in the London clay at the mouth of the Thames than are now known to exist in the whole world; and all the eocene *Chelones* are extinct. One of them (*C. gigas*, Ow.) attained unusual dimensions; the skull, now in the British Museum, measures upwards of a foot across its back part.[2] The estuary genus *Trionyx* (soft turtle) is represented by many beautiful species in the upper eocene at Hordwell; the fresh-water genera *Emys* and *Platemys* by as many species both at Sheppy and Hordwell. In the pliocene of Œningen remains of a species of *Chelydra* have been discovered; this generic form is now confined to America. Remains of land-tortoises (*Testudo*, Brong.) indicate several extinct species in the miocene and pliocene formations of continental Europe. Strata of like age in the Sewalik Hills have revealed the carapace of a tortoise 20 feet in length; it is called by its discoverers, Cautley and Falconer, *Colossochelys atlas*. The same locality has also afforded the interesting evidence of a species of *Emys* (*E. tectum*, Gray) having continued to exist from the (probably miocene) period of the *Sivatherium* to the present day.

ORDER XI.—BATRACHIA.

It is only in tertiary and post-tertiary strata that extinct species, referable to still existing genera or families of this order, have been found. The reptiles with amphibian or batrachian characters, of the carboniferous and triassic periods, combined those characters with others which gave them distinctions of perhaps ordinal value; they illustrated, indeed, rather a retention of more general cold-blooded vertebrate type, with concomitant piscine and saurian features, than any near affinity with the more specially modified reptilian forms to which the name *Batrachia* is given in zoological catalogues of existing species.

Of the tailless or "anourous" Batrachia, toads of extinct species (*Palæophrynos Gessneri* and *P. dissimilis*) have been discovered in the Œningen beds; and frogs, more abundantly, in both miocene and pliocene deposits of France and Germany. Of the salamander family, the most noted fossil is that which was referred, when first discovered at Œningen in 1726, to the human species, as *Homo diluvii testis*. Cuvier demonstrated its near affinities to the water-salamander (*Menopoma*) of the United States · more recently a living species of salamander has been discovered in Japan which equals in size the fossil in question—*Andrias Scheuzeri*.

A retrospect of the foregoing outline of the palæontology of the class of reptiles shows that, unlike that of fishes, it is now on the wane; and that the period when *Reptilia* flourished under the greatest diversity of forms, with the highest grade of structure, and of the most colossal size, is the mezozoic. The manifestation of the more generalized vertebrate structure is illustrated by the affinities to ganoid fishes shown by the *Ganocephala, Labyrinthodontia*, and *Ichthyosauria*; by the affinities of the *Pterosauria* to birds, and by the approximation of the *Dinosauria* to Mammals. It is also shown by the combination of modern crocodilian and lacertian characters in the Thecodonts and sauropterygian Enaliosaurs. Even the Chelonia of the Purbeck period illustrate the same principle, by the more typical number of modified hæmapophyses, or abdominal ribs, entering into the composition of their plastron. The diagram (fig. 78) gives a concise view of the geological relations, or distribution in time, of the principal groups of the class *Reptilia*. In the column opposite the right hand, the dark mark shows that the ganocephalous group represented by the *Archegosaurus* began, culminated, and ended in the carboniferous period. The Labyrinthodonts, culminating in the trias, disappear at the base of the oolitic system. Of the true *Batrachia*, those retaining the tail appear to have been at their maximum during the upper tertiary period, and to have begun to decline after that time; whilst the tailless genera and species are most numerous and various at the present day. The *Ophidia* resemble the *Anoura*, commencing in the older tertiary, and showing their maximum of development at the present day. The true procœlian, and especially the pleurodont lizards, commencing a little earlier in the chalk, have also gone on increasing in number and variety of forms to the present day. The acrodont group was represented by *Mosasaurus*, under the maximum of size, during the cretaceous period. The Thecodonts have but the partial affinity to modern *Lacertilia* which the Labyrinthodonts bear to the modern *Batrachia*. The great ordinal groups of *Enaliosauria, Pterosauria*, and *Dinosauria*, together with the amphi- and opistho-cœlian crocodiles, passed

[2] The upper end of the femur from Sheppy, in t. xxix. of *Monograph of Fossil Reptilia of the London Clay*, Palæontographical Society, 1850, belongs to this species.

away ere the tertiary time had dawned The procœlian crocodiles culminating in the lower and midd'e tertiary times are now on the wane. Perhaps, also, the same might be said of the *Chelonia*, in regard to the size of individuals, and number of species of certain genera; but the number of generic and subgeneric forms of the order now existing, as compared with the known extinct tertiary forms, is signified by the same expansion of the black mark as in the case of the lizards, serpents, frogs, and toads.

Table of Geological Distribution of Reptilia.

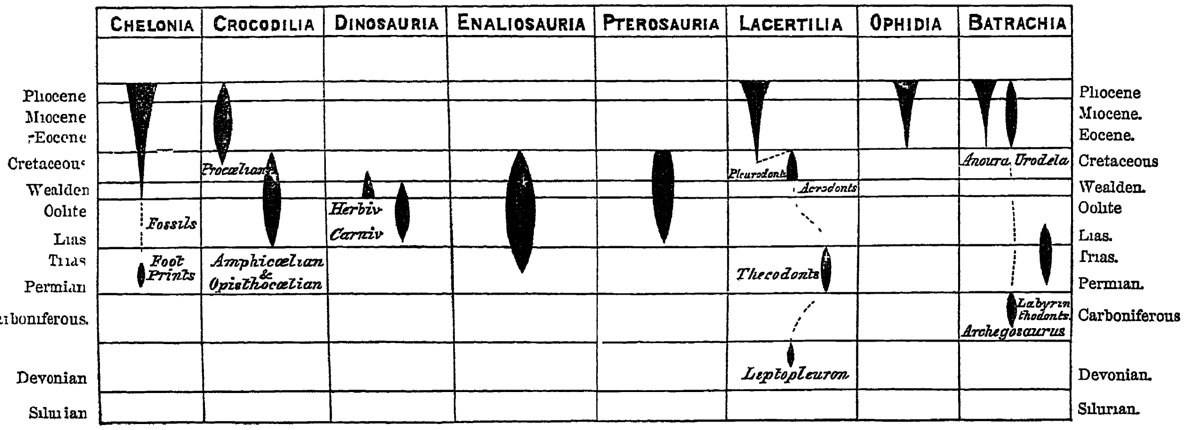

Fig. 78.

Class II.—AVES.

Long before any evidence of birds from actual or recognisable fossil remains is obtained in tracing the progress of life from the oldest fossiliferous deposits upwards, we meet with indications of their existence impressed in sandstones of the triassic or liassic period.

These earliest evidences of the class are by foot-prints in some former tidal shore, preserved in one or other of the ways explained in the section "Ichnology." The fossil bones of birds have not been found save in strata of much later date than the impressed sandstones; and they are much more rare than the remains of mammals, reptiles, and fishes, in any formations except the most recent in certain limited localities,—*e g*, New Zealand.

Sir C. Lyell has well remarked, that "the powers of flight possessed by most birds would insure them against perishing by numerous casualties to which quadrupeds are exposed during floods." The same writer further argues, that "if they chance to be drowned, or to die when swimming on water, it will scarcely ever happen that they will be submerged so as to become preserved in sedimentary deposits."[1] It is true that the carcase of a floating bird may not sink where it has died, but be carried far along the stream. ultimately, however, if not devoured, its bones will subside when the soft parts have rotted, and both the compactness of the osseous tissue, and the facts made known by the ornitholites of the greensand near Cambridge, of the London clay at Sheppy, and of the Montmartre eocene quarry-stone, show that they can be preserved in the fossil state. The length of time during which the carcase of a bird may float, doubtless exposes it the more to be devoured, and so tends to make more scarce the fossil remains of birds in sedimentary strata.

Certain it is that the major part of the remains of extinct birds that have as yet been found are those of birds that were deprived of the power of flight, and were organized to live on land.

The existence of birds at the triassic period in geology, or at the time of the formation of sandstones which are certainly intermediate between the lias and the coal, is indicated by abundant evidences of foot-prints impressed upon those sandstones which extend through a great part of the valley of the Connecticut River, in Connecticut and Massachusetts, North America.

The foot-prints of birds are peculiar, and more readily distinguishable than those of most other animals. Birds tread on the toes only; these are articulated to a single metatarsal bone at right angles equally to it, and they diverge more from each other, and are less connected with each other, than in other animals, except as regards the web-footed order of birds.

Not more than three toes are directed forward:[2] the fourth when it exists, is directed backward, is shorter, usually rises higher from the metatarsal, and takes less share in sustaining the superincumbent weight. No two toes of the same foot in any bird have the same number of joints. There is a constant numerical progression in the number of phalanges (toe-joints), from the innermost to the outermost toe. When the back toe exists, it is the innermost of the four toes, and it has two phalanges, the next has three, the third or middle of the front toes has four, and the outermost has five phalanges. When the back toe is wanting, as in some waders, and most wingless birds, the toes have three, four, and five phalanges respectively. When the number of toes is reduced to two, as in the ostrich, their phalanges are respectively four and five in number; thus showing those toes to answer to the two outermost toes in tridactyle and tetradactyle birds.

The same numerical progression characterizes the two phalanges in most lizards from the innermost to the fourth; but a fifth toe exists in them which has one phalanx less than the fourth toe. It is the fifth toe which is wanting in every bird In some *Gallinacea*, one or two (*Pavo bicalcaratus*) spurs are superadded to the metatarsus; but this peculiar weapon is not the stunted homologue of a toe. Dr Deane and Mr Marsh of Greenfield, United States, first noticed, in 1835, impressions resembling the feet of birds in the sandstone rocks near that town. Dr Hitchcock, president of Amherst College, United States, whose attention was called to these impressions, first made public the fact, and submitted to a scientific ordeal his interpretations of those impressions as having been produced by the feet of living birds, and he gave them the name of *Ornithichnites*.

It was a startling announcement, and a conclusion that must have had strong evidence to support it, since one of the kinds of the tracks had been made by a pair of feet, each leaving a print 20 inches in length. Under the term *Ornithichnites giganteus*, however, Dr Hitchcock did not shrink from announcing to the geological world the fact of the existence, during the period of the deposition of the red sandstones of the valley of the Connecticut, of a bird which must have been at least four times larger than the ostrich[3] The impressions succeeded each other at regular intervals; they were of two kinds, but differing only as a right and left foot, and alternating with each other, the left foot a little to the left, and the right foot a little to the right, of the mid-line between the series of tracks. Each foot-print (fig. 79, *b* and *r*) exhibits three toes, diverging as they extend forwards. The distance between the tips of the inside and outside toes of the same foot was 12 inches. Each toe was terminated by a short strong claw projecting from the mid toe a little on the inner side of its axis, from the other two toes a little on the outer side of theirs. The end of the metatarsal bone to which those toes were articulated rested on a two-lobed cushion which sloped upwards behind. The inner toe (*r*) showed distinctly two phalangeal divisions, the middle toe three, the outer toe (*b*) four. And since, in living birds, the penultimate and ungual phalanges usually leave only a single impression, the inference was just, that the toes of this large foot had been characterized by the same progressively-increasing number of phalanges, from the inner to the outer one, as in birds. And, as in birds also, the toe with the greatest number of joints was not

[1] *Principles of Geology*, ed. 1847, p. 721.
[2] Save in the Swift.
[3] *American Journal of Science* for 1836, vol xxix, pl. i

Aves.

the longest; it measured, *e.g.*, 12½ inches, the middle toe from the same base-line measured 16 inches, the outer toe 12 inches. Some of the impressions of this huge tridactylous footstep were so well preserved as to demonstrate the papillose and striated character of the integument covering the cushions on the under side of the foot. Such a structure is very similar to that in the ostrich. The average extent of stride, as shown by the distance between the impressions, was between 3 and 4 feet; the same limb was therefore carried out each step from 6 to 7 feet forward in the ordinary rate of progression.

These foot-prints, although the largest that have been observed on the Connecticut sandstones, are the most numerous. The gigantic Brontozoum, as Principal Hitchcock proposes to term the species, "must have been," he writes, "the giant rulers of the valley. Their gregarious character appears from the fact, that at some localities we find parallel rows of tracks a few feet distance from one another."

The strata of red sandstone, with the above-described impressions, occupy an area more than 150 miles in length, and from 5 to 10 miles in breadth "Having examined this series of rocks in many places, I feel satisfied that they were formed in shallow water, and for the most part near the shore; and that some of the beds were from time to time raised above the level of the water and laid dry, while a newer series, composed of similar sediment, was forming." "The tracks have been found in more than twenty places, scattered through an extent of nearly 80 miles from N. to S., and they are repeated through a succession of beds attaining at some points a thickness of more than 1000 feet, which may have been thousands of years in forming."[1]

One of the evidences of birds from the Cambridge greensand, transmitted to the writer by their discoverer, Mr Barret, is the lower half of the trifid metatarsal, showing the outer toe-joint much higher than the other two, and projecting backwards above the middle joint; it indicates a bird about the size of a woodcock.

In the conglomerate and plastic clay at the base of the eocene tertiary system at Mendon, near Paris, the leg and thigh bones (tibia and femur) of a bird (*Gastornis Parisiensis*) have been discovered: they indicate a genus now extinct. They belonged to a species as large as an ostrich, but more robust, and with affinities to wading and aquatic birds.[2] In the eocene clay of Sheppy fossil remains of birds have been found, indicating a small vulture (*Lithornis vulturinus*); also a bird, probably of the king-fisher family (*Halcyornis toliapicus*), and a species of the sea-gull family. In the same formation at Highgate remains of a species of the heron family have been found.

The fossil bones of birds from the gypsum quarries at Montmartre were referred or approximated by Cuvier to eleven distinct species. Good ornitholites have been obtained from the Hordwell fresh-water deposits. The most ancient example of a passerine bird is the *Protornis Glarisiensis*, founded on an almost entire skeleton discovered in the schistose rock of Glaris, referable to the older division of the eocene tertiary series. This skeleton is about the size of a lark, and in some respects similar to that bird.

Comparisons of the ornitholites of the eocene tertiaries show that the following ordinal modifications of the class of birds were at that period represented, the *raptorial*, or birds of prey, by species of the size of our ospreys, buzzards, and smaller falcons, and most probably also by an owl; the *insessorial*, or tree-perching birds, by species seemingly allied to the nuthatch and the lark; the *scansorials* or anisodactyles, by species as large as the cuckoo and king-fisher; the *rasorials*, by a species of small quail; the *cursorials*, by a species as large as, but with thicker legs than, an ostrich; the *grallatorial*, by a curlew of the size of the ibis, and by species allied to *Scolopax*, *Tringa*, and *Pelidna*, of the size of our woodcocks, lapwings, and sanderlings; and the *natatorial*, by species allied to the cormorant, but one of them of larger size, though less than a pelican; also by a species akin to the divers (*Merganser*).

The remains of birds become more abundant and varied as we approach the present time; especially in the miocene strata, so richly developed in France, although wanting in Britain. One of the most singularly-modified forms of beak is shown by the flamingo. The fossil skull of a species of this genus (*Phœnicopterus*) has been found in the miocene fresh-water deposits of the plateau of Gergovia, near Clermonte-Ferrand; the entire metatarsal bone of a species of eagle (*Aquila*) or osprey (*Pandion*) in the same deposits at Chaptusal, Allier; and the humerus of a bird allied to and as large as the albatross, in the *molasse coquilliére marine* at Armagne. Remains of a vulture, most probably a *Cathartes*, have been found in the miocene lacustrine deposits of Cantal. Indications of all the other orders of birds, save the great Cursores or *Struthionidæ*, have also been discovered in miocene strata—those of wading birds being the most numerous. Fossil eggs of birds occur in miocene deposits in Auvergne; and impressions of feathers have been discovered in the pliocene calcareous marls at Montebolca. In pliocene brick-earth deposits in Essex has been found a fossil metatarsal of a swan, as large as, and not distinguishable from, the existing wild swan; in the pleistocene clay at Lawford a fossil humerus like that of a wild goose. But most of the ornitholites of this recent tertiary period have been discovered in ossiferous caverns. They belong to birds closely resembling the falcon, wood-pigeon, lark, thrush, teal, and a small wader. The writer has received information of skeletons of birds found deeply imbedded in stratified clay at Aberdeen and Peterhead. The most remarkable additions to the present class have been obtained from the superficial deposits, turbaries, and caves in New Zealand[3] This island is remarkable for the absence of aboriginal species of land-mammals, and for the presence of a small bird with very rudimental wings, and the keelless sternum and loose plumage of the Struthious order, but of a peculiar genus called *Apteryx*: the legs are very robust, and have three front toes and a very small back toe. Birds resembling the *Apteryx* in the shape of the sternum and bony structure of the pelvis and hind limbs, some retaining also the small back toe, others apparently without it, formerly existed in New Zealand under different specific forms ranging in height from 3 feet to 10 feet. They have been referred by the writer to the genera *Dinornis* and *Palapteryx*. The gigantic species are interesting as exhibiting birds equal to the formation of tridactyle impressions as large as those of the Connecticut sandstones called *Ornithichnites* (*Brontozoum*) *gigas* (fig. 79, *r*, *b*). In that cut is given a figure of the leg-bones of *Dinornis giganteus*, in which the tibia (*t*) measures upwards of a yard in length. In the entire skeleton (*A*) of another species, the metatarsus is as thick, but only half as long, as in the *D. giganteus*; the framework of the leg is the most massive of any in the class of birds; the toe-bones almost rival those of the elephant; whence the name *Dinornis elephantopus*, given to this species. Several other species of these

[1] Lyell, *Manual of Elementary Geology*, 8vo, 1855, p. 348.
[2] Owen "On the Affinities of *Gastornis Parisiensis*," *Quarterly Journal of Geological Society*, vol. xii., 1856, p. 204.
[3] These remains are described in eight memoirs by the writer, published in the third and fourth volumes of the *Transactions of the Zoological Society of London*. The description of the first fragment of the bone, indicative of the *Dinornis*, is in vol. iii., p. 39, pl. 3.

extinct tridactyle wingless birds have been determined—*e.g.*, *Dinornis ingens*, *D. struthioides*, *D. rheides*, *D. dromioides*, *D. casuarinus*, *D. robustus*, *D. crassus*, *D. geranoides*, *D. curtus*. With these remains have been found bones of a bird the size of a swan, but of an extinct genus (*Aptornis*); also those of a large coot (*Notornis Mantelli*) which, founded originally on fossil remains, was afterwards discovered living in the Middle Island of New Zealand. Two species of *Apteryx*, not distinguishable from the existing kinds, were contemporaries with the gigantic *Dinornis*, and the writer has received evidence that the *D. elephantopus* afforded food to the natives at probably no very remote period. Some of the smaller kinds of *Dinornis* may yet be found living on the Middle Island.

In Madagascar portions of metatarsal bones, indicating a three-toed bird as large as, but generically distinct from, the *Dinornis giganteus*, have been discovered in alluvial banks of streams; and with them entire eggs, measuring from 13 to 14 inches in long diameter. The contents of one of these eggs is computed to equal those of six ostrich eggs, or of one hundred and forty-eight hen's eggs.

In the neighbouring island of Mauritius the dodo (*Didus ineptus*) has been exterminated by man within the period of two centuries; and in the islands of Bourbon and Rodriguez the "solitaire" (*Pezophaps*) has also become extinct. Both these birds had wings too short for flight.

CLASS III.—MAMMALIA.

(Warm-blooded, Air-breathing, Viviparous Vertebrates.)

Every calcified part of an animal, whether coral, shell, crust, tooth, or bone, can preserve its form and structure when buried in the earth during the changes there gradually operated in it, until every original particle may have been removed and replaced by some other mineral substance previously dissolved in the water percolating the bed containing the fossil. A bone, or other part so altered, is said to be "petrified." Not only are all its outward characters preserved, but even the minutest structure may be, and in most cases is, demonstrable in the fine sections under the microscope.

Fossil bones and teeth have been discovered in every intermediate stage of alteration, from their recent state to that of complete petrifaction. Recent bones consist of a soft,—commonly called animal or organic,—basis, hardened by earthy salts, chiefly phosphate of lime.[1] Fishes have the smallest proportion, birds the largest proportion, of the earthy matter in their bones. The soft part is chiefly a gelatinous substance.

Proportions of Hard and Soft Matter in the Bones of the Vertebrate Animals.

FISHES.

	Salmon.	Carp.	Cod.
Soft	.60·62	40 40	34·30
Hard	.39·38	59·60	65·70
	100·00	100·00	100·00

REPTILES.

	Frog.	Snake.	Lizard.
Soft	.35·50	31·04	46 67
Hard	.64·50	69·96	53·33
	100·00	100·00	100·00

MAMMALS.

	Porpoise.	Ox.	Lion.	Man.
Soft	.35·90	31·00	27 70	31·03
Hard	.64·10	69·00	72·30	68·97
	100·00	100·00	100·00	100·00

BIRDS.

	Goose.	Turkey.	Hawk.
Soft	.32·91	30·49	26·72
Hard	.67·09	69·51	73·28
	100·00	100·00	100·00

The chemical nature of the hardening particles, and of the soft basis of bone, is exemplified in the subjoined table, including a species of each of the four classes of Vertebrata:—

Chemical Composition of Bones.

Ingredients,	Hawk.	Man.	Tortoise.	Cod.
Phosphate of lime, with trace of fluate of lime ..	64·39	59·63	52·66	57·29
Carbonate of lime	7 03	7·33	12·53	4·90
Phosphate of magnesia	0 94	1 32	0 82	2·40
Sulphate, carbonate, and chlorate of soda	0·92	0 69	0·90	1·10
Glutin and chondrin	27 73	29 70	31·75	32·31
Oil	0 99	1 33	1·34	2 00
	100 00	100 00	100 00	100·00

The most common change which bones first undergo is the loss of more or less of their original soft and soluble basis. This effect of long interment is readily tested by applying the specimen to the tongue, when the affinity of the pores of the earthy constituent, after having lost the gelatine, for fluid is so great, that the specimen adheres to the tongue like a piece of dry chalk. Bones and teeth in this state quickly absorb a solution of gelatine, and thus their original tenacity may be restored.[2] Petrified fossils need no such treatment; they are usually harder and more durable than the original bone itself.

The interpretation of such fossil remains requires a comparison of them with the corresponding parts of animals now living, or of previously determined extinct species. In the case of the vertebrate animals, such comparison is limited to the osseous and dental systems. The interpretation of a vertebrate fossil, therefore, presupposes a knowledge of the various modifications of the skeleton and teeth of the existing vertebrate animals; and the more extensive and precise such knowledge may be, the more successful will be the efforts, and the more exact the conclusions, of the interpreter.

The determination of the remains of quadrupeds is beset, as Cuvier truly remarks, with more difficulties than that of other organic fossils. Shells are usually found entire, and with all the characters by which they may be compared with their analogues in the museums, or with figures in the illustrated books, of naturalists. Fishes frequently present their skeleton or their scaly covering more or less entire, from which may be gathered the general form of their body, and frequently both the generic and specific characters which are derived from such internal or external hard parts. But the entire skeleton of a fossil quadruped is rarely found, and when it occurs, it gives little or no information as to the hair, the fur, or the colour of the species. Portions of the skeleton with the bones dislocated, or scattered pell-mell,—detached bones and teeth, or their fragments merely,—such are the conditions in which the petrified remains of the mammalian class most commonly present themselves in the strata in which they occur.

Prior to the time of Cuvier but little progress had been made in the interpretation of such fragmentary remains. The striking success which attended the application of the great comparative anatomist's science to this previously neglected field of study, was referred by Cuvier to principles in the organization of animal bodies, which he termed the "Correlation of Forms and Structures," and the "Subordination of Organs,"—principles which his philosophical biographer, M. Flourens,[3] in common with most contemporary philosophers, has regarded as the most effective and successful instrument in the restoration of extinct animals. They will be exemplified in the course of the present and concluding section of the article PALÆONTOLOGY.

A terminal phalanx modified to fit a hoof may give, as Cuvier declared, the modifications of all the bones of the fore limb that relate to the absence of a rotation of the fore leg, and all the modifications of the jaw and skull that relate to the mastication of food by broad-crowned complex molars.

But there are certain associated structures for the coincidence of which the physiological law is unknown. "I doubt," writes Cuvier, "whether I should have ever divined, if observation had not taught it me, that the ruminant hoofed beasts should all have the cloven foot, and be the only beasts with horns on the frontal bone."[4] We know as little why horns should be in one or two pairs on the frontal bone of those Ungulates only which have hoofs in one or two pairs; whilst in the horned Ungulates with three

[1] That this combination of phosphorus and calcium has ever taken place in nature, save under the influences of a living organism, remains to be proved.

[2] The writer's experience of this effect led him to suggest the application of a similar process to the long-buried ivory ornaments from the ruins of Nineveh in the British Museum; it proved successful.

[3] *Eloge Historique et l'Analyse Raisonnée des Travaux de G. Cuvier*, 12mo, Paris, 1841, p. 42.

[4] *Ossemens Fossiles*, 8vo, ed. 1834, tom. i., p. 184.

hoofs, there should be either one horn, or two horns placed one behind the other in the middle line of the skull; or why the Ungulates with one or three hoofs on the hind foot should have three trochanters on the femur, whilst those with two or four hoofs on the hind foot should have only two trochanters.

"However," continues Cuvier, "since these relations are constant, they must have a sufficing cause; but as we are ignorant of it, we must supply the want of the theory by means of observation.[1] This, if adequately pursued, will serve to establish empirical laws almost as sure in their application as rational ones." "That there are secret reasons for all these relations, observation may convince us independently of general philosophy." "The constancy between such a form of such organ, and such another form of another organ, is not merely specific, but one of class, with a corresponding gradation in the development of the two organs."[2]

"For example, the dentary system of non-ruminant Ungulates is generally more perfect than that of the Bisulcates; inasmuch as the former have almost always both incisors and canines in the upper as well as the lower jaw; the structure of their feet is in general more complex, inasmuch as they have more digits, or hoofs less completely enveloping the phalanges, or more bones distinct in the metacarpus and metatarsus, or more numerous tarsal bones; or a more distinct and better developed fibula; or a concomitance of all these modifications. It is impossible to assign a reason for these relations; but, in proof that it is not an affair of chance, we find that whenever a bisulcate animal shows in its dentition any tendency to approach the non-ruminant Ungulates, it also manifests a similar tendency in the conformation of its feet. Thus the camels, which have canines and two or four incisors in the upper jaw, have an additional bone in the tarsus, resulting from the scaphoid not being confluent with the cuboid; and the small hoofs have correspondingly small phalanges. The musk-deer, which have long upper canines, have the fibula co-extensive with the tibia, whilst the other ruminants have a mere rudiment of fibula articulated to the lower end of the tibia." "There is then a constant harmony between two organs to all appearance quite strangers to each other, and the gradations of their forms correspond uninterruptedly even in the cases where one can render no reason for such relations." "But in thus availing ourselves of the method of observation as a supplementary instrument when theory abandons us, we arrive at astonishing details. The smallest articular surface (*facette*) of a bone, the smallest process, present a determinate character relating to the class, to the order, to the genus, and to the species to which they belong; so that whoever possesses merely the well-preserved extremity of a bone, he may, with application, aided by a little tact (*adresse*) in discerning analogies, and by sufficient comparison, determine all these things as surely as if he possessed the entire animal."[3]

There have been, of course, instances, and will be, where, for want of the "efficacious comparison," and the "tact in discerning likeness," such results have not rewarded the endeavours of the palæontologist; and these shortcomings, and the mistakes sometimes made, even by Cuvier himself, have been cast in the teeth of his disciples, as arguments against the principles by which they believed themselves guided in their endeavours to complete the glorious edifice of which their master laid the foundations.

The writer has, therefore, quoted from the well-known "Preliminary Discourse" to Cuvier's great work on Fossil Remains, with a view to neutralize the efforts of statements reiterated in apparent ignorance of the clear and explicit manner in which Cuvier there defines the limits within which the law of correlation of animal structures may be successfully applied, and indicates the instances in which,—the physiological condition being unknown, and the coincident structures being understood empirically,—careful observation and rigorous comparison must supply the place of the physiologically-understood law.

Those who deny the existence of design in the construction of any part of an organized body, and who protest against the deduction of a purpose from the valves of the veins or the lens of the eye-ball, repudiate the reasoning which the palæontologist carries out from the hoof to the grinder, or from the carnassial molar to the retractile claw, through the guidance of the principle of a pre-ordained mutual adaptation of such parts; but such minds are not, nor have been, those who have contributed to the real advancement of physiology or palæontology.

By reference to the "Table of Strata" (fig. 1), it will be seen that the earliest evidence of a vertebrate animal is of the cold-blooded water-breathing class in the upper Silurian period. Next follows that of a cold-blooded but air-breathing vertebrate, probably from the upper Devonian, but, under the batrachian grade, certainly in the carboniferous period. The warm-blooded air-breathing classes are first indicated, as birds, by foot-marks in a sandstone of probably triassic but not older age; and, as Mammals, by fossil teeth from bone-beds of the upper triassic system in Wirtemberg, and of the same age near Frome, Somersetshire. Mammalian remains have also been found in a coal-field in North Carolina, which may be earlier, but cannot be later, than the lias formation.

Genus MICROLESTES.—The mammalian teeth from German and English trias indicate a very small insectivorous quadruped, to which the above generic name was given by Professor Plieninger. The German specimens were discovered in 1847 in a bone breccia at Diegerloch, about two miles from Stuttgardt, the geological relations of which are well determined as between lias and Keuper sandstone. The teeth of *Microlestes* from Frome, submitted to the writer by the discoverer, Mr Charles Moore, F.G.S., in 1858, are four in number, two being molars of the upper jaw, each with four fangs; one a molar with a narrower crown and two fangs from the lower jaw; and the fourth a small, pointed, front tooth. The crowns of the molars are short vertically in proportion to their breadth; the distinct enamel contrasts with the cement-covered fangs; the grinding surface shows a wide and shallow depression, surrounded by small, low, obtuse cusps, three of equal size being on one side, a larger cusp near one end, and smaller and less regular cusps on the side opposite the three. The lower molar shows a similar type, but with the three marginal cusps less equal in size. The crown of the largest of the upper molars does not exceed one line in its longest diameter. Amongst existing Mammals, some of the small molars of the marsupial and insectivorous *Myrmecobius* of Australia offer the nearest resemblance to these fossil teeth; but a still closer one is presented by the small tubercular molars of the extinct oolitic Mammal called *Plagiaulax* (fig. 88, *m*, 1 and 2).

Genus DROMATHERIUM.—It would appear that the Mammal from the American triassic or liassic coal-bed (*Dromatherium sylvestre*, Emmons) also found its nearest living analogue in *Myrmecobius*; for each ramus of the lower jaw contained 10 small molars in a continuous series, 1 canine, and 3 conical incisors, the latter being divided by short intervals.

Genus AMPHITHERIUM (*Thylacotherium*, Val.)[4]—This genus is

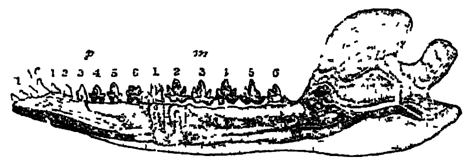

Fig. 80.

Lower Jaw and Teeth of the *Amphitherium Prevostii* (twice nat. size).

founded upon a few specimens of lower jaw, one ramus of which (fig. 80) gave the entire dentition of its side,—viz., three small conical incisors (*i*), one rather larger canine (*c*), six premolars, unicuspid, with a small point at one or both sides of the base (*p*, 1–6), and six quinque-cuspid molars (*m*, 1–6) not departing very far from the type above-described. The molars, and most of the premolars, are implanted by two roots. The condyle of the jaw is convex, and is a little higher than the level of the teeth; the coronoid process is broad and high; the angle projects backward, with a feeble production inward. It is, again, to the marsupial *Myrmecobius*, amongst living forms, that the present genus is most nearly allied. The remains of *Amphitherium* are from the lower oolitic slates of Stonesfield (fig. 82, stratum 8).

Genus AMPHILESTES.[5]—This genus is founded on a ramus of the lower jaw, from the Stonesfield oolitic slate, showing true molars of a compressed form, with a large middle cusp and a smaller, but well-marked, one at the fore and back part of its base; the "cin-

[1] "Puisque ces rapports sont constants, il faut bien qu'ils aient une cause suffisante; mais comme nous ne la connoissons pas, nous devons suppléer au défaut de la théorie par le moyen de l'observation." (Tom. cit., p. 184.)

[2] "En effet, quand on forme un tableau de ces rapports, on y remarque non-seulement une constance spécifique, si l'on peut s'exprimer ainsi, entre telle forme de tel organe, et telle autre forme d'un organe différent; mais l'on aperçoit aussi une constance de classe et une gradation correspondante dans le développement de ces deux organes, qui montrent, presque aussi bien qu'un raisonnement effectif, leur influence mutuelle." (Tom. cit., p. 185.)

[3] Tom. cit., p. 187.

[4] For the full description and demonstration of the mammalian nature of this much-discussed fossil, see Owen, *History of Brit. Fossil Mammals*, 8vo, p. 29.

[5] Owen, *Hist. Brit. Foss. Mam.*, p. 58, fig. 19 (*Amphitherium Broderipii*).

gulum," or basal ridge, peculiar to mammalian teeth, traverses the inner ridge of the crown, where it develops three small cusps, one at the base of the large outer or principal cusp, and the other two forming the anterior and posterior ends of the crown. This form of tooth is unknown in existing Mammalia, but is as well adapted for crushing the cases of coleopterous insects (elytra of which are found fossil in the same oolitic matrix) as are any of the multicuspid molars of small opossums, shrews, and bats. The *Amphilestes Broderipii* was somewhat larger than *Amphitherium Prevostii*.

Genus PHASCOLOTHERIUM.—Although the evidence of the very slight degree of inflection of the angular process of the lower jaw of *Amphitherium* may favour its affinity to the placental Insectivores, yet the range of variety to which that mandibular character is subject in the different genera of existing *Marsupialia* warns us against laying undue stress upon its feeble development in the extinct genus of the oolitic epoch, and incites us to look with redoubled interest at whatever other indications of a marsupial character may be present in the fossil remains of other genera and species of Mammalia that have been detected in the Stonesfield slate.

In the specimen of *Phascolotherium* (fig. 81) presented to the

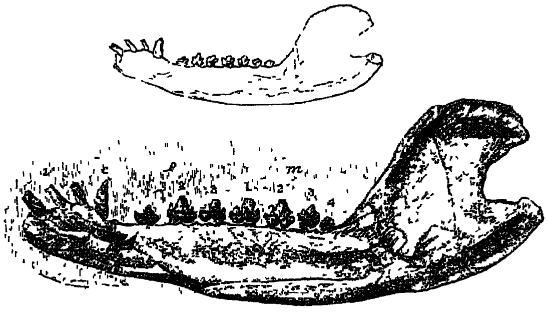

Fig. 81.

Lower Jaw and Teeth of the *Phascolotherium* (nat. size in outline), Lower Oolite.

British Museum by William J. Broderip, Esq., F.R.S., its original describer,[1] which is as perfect in regard to the dentition as the jaw of the *Amphitherium* above described, the marsupial characters are more strongly manifested in the general form of the jaw, and in the extent and position of the inflected angle, while the agreement with the genus *Didelphys* in the number of the premolar and molar teeth is complete. The forms of the crowns of those teeth differ from those in *Didelphys*, and correspond so closely with those in the *Amphilestes Broderipii*, as to show the closer affinity of the Phascolothere with the latter oolitic Insectivora; and, accordingly, whatever additional evidence of marsupiality is afforded by the *Phascolotherium*, may be regarded as strengthening the claims of both *Amphilestes* and *Thylacotherium* to be admitted into the marsupial group. The general form and proportions of the coronoid process of the jaw of *Phascolotherium* resemble those in the zoophagous Marsupials; and especially with that of the *Thylacynus* in regard to the depth and form of the entering notch between this process and the condyle.

The base of the inwardly-bent angle of the lower jaw progressively increases in *Didelphys*, *Dasyurus*, and *Thylacinus*; and judging from the fractured surface of the corresponding part of the fossil, it most nearly resembles the jaw of *Thylacinus*. The condyle of the jaw is nearer the plane of the inferior margin of the ramus in the Thylacine than in the Dasyures or Opossums; and consequently, when the inflected angle is broken off, the curve of the line continued from the condyle along the lower margin of the jaw is least in the Thylacine. In this particular, again, the Phascolothere resembles that Australian Carnivore. In the position of the dental foramen, the Phascolothere, like the Amphithere, differs from the zoophagous Marsupials and placental Carnivora and Insectivora, and resembles the *Hypsiprymnus*, a marsupial Herbivore, that orifice being near the vertical line dropped from the last molar tooth. In the direction of the line of the symphysis, the Phascolothere resembles the Opossums more than the Dasyures or Thylacines. It is probable that the teeth at the fore part of the jaw showed the same correspondence. In the number of the molar series, the Phascolothere differs from *Amphitherium*, *Amphilestes*, and *Myrmecobius*, and resembles the Thylacine and Opossum, but without having the premolars (*p*, 1, 2, 3) distinguished, as in them, from the true molars (*m*, 1, 2, 3, 4), by smaller and more simple crowns. As, however, these two kinds of teeth can only be determined by their order of development and succession, the Phascolothere may well have had three premolars and four true molars.

The difference between these teeth in the lower jaw of *Didelphys* is shown by the addition, in the true molars, of a pointed tubercle on the inner side of the middle cone. In *Phascolotherium* a mere basal ridge or cingulum extends along the inner side of the middle cone. Such a ridge is present in the last molar of *Sarcophilus*, but not in the other molars; but in these there are two small hind cusps on the same transverse line, whilst that cusp appears to be single in *Phascolotherium*. The cingulum, moreover, in the second to the penultimate of the molar series of this fossil, extends so far as to form a small talon at the fore and back part of the crown; thus making five points, which are very distinct in the third to the penultimate tooth inclusive; and by this character the dentition of *Phascolotherium* differs materially from any existing Marsupial, and repeats the type of molar which, as yet, would seem to be peculiar to the Insectivora of the oolitic epoch. There is a feeble indication of this structure in the antepenultimate and penultimate molars of *Thylacinus*, but the hinder division of the crown shows two small cusps on the same transverse line, besides the rudimental hindmost one; and there is no cingulum. Upon the whole, it would seem that, though the affinity may not be close, *Phascolotherium* most resembles *Thylacinus* amongst existing Mammals; but *Thylacinus* is now confined to Tasmania, and is there fast verging to extinction.

The resemblance shown by the lower jaw and its teeth of the Amphithere and Phascolothere to marsupial genera now confined to Australia and Tasmania, leads one to reflect on the interesting correspondence between other organic remains of the Oxfordshire oolite and other existing forms now confined to the Australian con-

tinent and surrounding sea. Here, for example, swims the Cestracion, or Port-Jackson shark, which has given the key to the nature of the "palates" from our oolites, now recognised as the teeth of congeneric larger forms of cartilaginous fishes. Mr Broderip, in his Memoir above quoted, observes, "that it may not be uninteresting to note that a recent species of *Trigonia* has very lately been discovered on the coast of Australia, that land of marsupial animals. Our specimen lies imbedded with a number of fossil shells of that genus." Not only *Trigoniæ* but *Terebratulæ* exist, and the

[1] *Zoological Journal*, vol. iii., p. 408, pl. xl., 1828.

latter abundantly, in the Australian seas, yielding food to the Cestracion, as their extinct analogues doubtless did to the allied Plagiostomes with crushing teeth, called *Acrodus*, *Psammodus*, &c. *Araucariæ* and cycadeous plants, like those found fossil in oolitic beds, flourish on the Australian continent, where marsupial quadrupeds now abound; and thus appear to complete a picture of an ancient condition of the earth's surface, which has been superseded in our hemisphere by other strata and a higher type of mammalian organization. Fig. 82 represents a section of the strata overlying the slates whence the fossil mammalian jaws, with associated Megalosaurs, Pterodactyles, and other oolitic organisms, have been obtained at Stonesfield in Oxfordshire. The vertical thickness of the strata through which the shaft is sunk to the gallery is 62 feet; on the side opposite the right hand is marked the depth of the horizontal gallery, where the slate is dug which contains the fossils; on the opposite side the strata are numbered in succession.

Genus STEREOGNATHUS.—The last evidence of a mammalian animal discovered in the Stonesfield slate is of peculiar interest, because it exhibits a type of grinding teeth quite distinct from any of the previously acquired jaws from that locality, and affords evidence of a small vegetable-feeding or omnivorous quadruped. It consists of a portion of a lower jaw, imbedded in the characteristic matrix (fig. 83), about 9 lines in extent, and containing three molar teeth (*a*, *b*, *c*). It is nearly straight; the side exposed is convex vertically; a slight bend downwards, and decrease of vertical diameter towards the end, indicates it to be part of a left ramus. This is unusually shallow, broad or thick below, the side passing by a strong convex curve into the lower part; a very narrow longitudinal ridge, continued after its subsidence by a few fine lines, forms a tract which divides the lateral from the under surface; elsewhere the bone is smooth, without conspicuous vascular perforations. The depth or vertical diameter of the ramus is not more than 2 lines. Of the three teeth remaining in this portion of jaw, the middle one is the least mutilated. The crown of this tooth (fig. 84, *B*) is of a quadrate form, 3 millimetres by 3½ millimetres, of very little height, and supports six subequal cusps in three pairs, each pair being more closely connected in the antero-posterior direction of the tooth than transversely.

Fig. 83.

Stereognathus; Portion of Jaw, imbedded in Oolitic Matrix (nat. size).

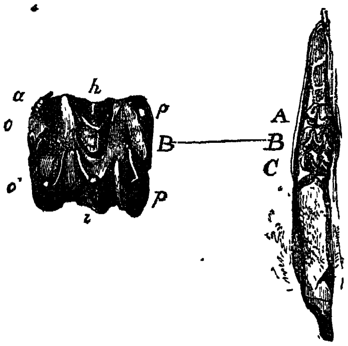

Fig. 84.

Stereognathus; Upper View of portion of Jaw (nat. size), and Magnified View of the Middle Tooth, *B* (Stonesfield Oolite).

The outer side of the crown (fig. 83, *b*), supported by a narrow fang which contracts as it sinks into the socket, shows two principal cusps or cones, and a small accessory basal cusp. The hard and shining enamel which covers these parts of the crown contrasts with the lighter cement that coats the root. The two outer lobes or cones are subcompressed, and placed obliquely on the crown, so that the hinder one (*o'*, fig. 84) is a little overlapped externally by the front one *o*, the fore part of the base of the hinder one being prolonged inwards on the inner side of the base of the front cone. The two middle cones (*h*, *i*) are subcompressed laterally, with the fore part of their base a little broader than the back part. The two inner cones (*p*, *p'*) have their inner surface convex, with their summits slightly inclined forwards. The fore part of the base of the hinder cone is prolonged obliquely towards the centre of the crown, beyond the contiguous end of the base of the front cone, so as to cause an arrangement like that of the two outer cones (*o*, *o'*), the obliquity of the posterior cone of both the outer and the inner pairs being such that they slightly converge as they extend forwards.

This type of tooth differs from that of all other known recent or extinct Mammals. The nearest approach to it is made by the middle true molar of *Pliolophus vulpiceps*, a small extinct herbivorous Mammal from the London clay (fig. 91, *m*, 2).

That the fragment in question is the jaw of a Mammal is inferred from the implantation of the tooth by two or more roots. Most Mammals are known to have certain teeth so implanted. Such complex mode of implantation in bone has not been observed in any other class of animals. Why two or more roots of a tooth should be peculiar to viviparous quadrupeds, giving suck, is not precisely known. That a tooth, whether it be designed for grinding hard or cutting soft substances, should do both the more effectually in the ratio of its firmer and more extended implantation, is intelligible. That a more perfect performance of the preparatory act of digestion should be a necessary correlation, or be in harmony with a more complete conversion of the food into chyle and blood,—and that such more efficient type of the whole digestive machinery should be correlated, and necessarily so, with the hot blood, quick-beating heart and quick-breathing lungs, with the higher instincts, and more vigorous and varied acts of a Mammal, as contrasted with a cold-blooded reptile or fish,—is also conceivable. To the extent to which such and the like reasoning may be true, or in the direction of the secret cause of the constant relations of many-rooted teeth discovered by observation,—to that extent will such relations ascend from the empirical to the rational category of laws.

The interest which the above-described fossil from the Stonesfield oolitic slate excites is not exclusively due to its antiquity, its uniqueness, or its peculiarity; much is attached to its relations as a test in palæontology of the actual value of a single tooth in the determination of other parts of the organization of the animal. According to our opinion of these unseen parts, we frame our expression of the nature and affinities, or of the place in the zoological system, of the extinct species. From the resemblance of the lower molars of *Stereognathus* to those of *Pliolophus*, which, though not close, is closer than to the teeth of any other known animal, it is probable that the *Stereognathus* was hoofed, and consequently herbivorous, or deriving the chief part of its subsistence from the vegetable kingdom. Cuvier has written,—"La première chose à faire dans l'étude d'un animal fossile est de réconnaitre la forme de ses dents molaires; ou determine par la s'il est carnivore ou herbivore, et dans ce dernier cas, on peut s'assurer, jusqu'à un certain point de l'ordre d'herbivores auquel il appartient."[1] In the case in question the form of the molar teeth of one jaw is recognisable, but the herbivority of the fossil is not thereby determined. We can only infer it to be more probable that the fossil was a Herbivore than an Insectivore or a mixed-feeding Carnivore.

Admitting the herbivority of the fossil, it is not certain that it was hoofed; there is nothing in the form and structure of the tooth to prove that. Both form and structure are compatible with the hoofless muticate type of herbivorous Mammal, as shown by the Manatee; it is the small size of the *Stereognathus* which renders it less probable that it was a diminutive kind of Manatee, and more probable that it was a diminutive form of Ungulate. But seeing the manifold diversities of the multi-cuspid form of molar teeth in recent and extinct insectivorous unguiculate quadrupeds, it is not impossible but that the *Stereognathus* may have belonged to that order; there is no known physiological law forbidding it.

The form of the cusps, and their regular symmetrical arrangement in the *Stereognathus*, as compared with the known modifications of multi-cuspid molars in certain small extinct forms of hoofed quadrupeds, constitute the grounds upon which an opinion is formed of its most probably belonging to the same section of *Ungulata*.

Then, is it not true, it may be asked, that by virtue of certain established laws of correlated structures, an extinct animal may be re-constructed from a single tooth or from a fragment of bone? Is the Cuvierian basis, or what has been so regarded, of palæontology unsound? Not necessarily from aught that has been said or written on the subject of the *Stereognathus*. We do not know the comparative anatomy of the family of quadrupeds to which the *Stereognathus* belonged. What we do know of its teeth suggests that that family may have had modifications of the skeleton so far differing from those of any, the modifications of which are known, as to have constituted a type of, perhaps, a marsupial family, but a type as well marked, and as distinct, as the type of skeleton which Cuvier inductively studied in the feline *Carnivora* (fig. 106), and in the ruminant *Herbivora* (fig. 107), and by which preliminary study he was enabled to enunciate that beautiful law of the "correlation of forms and structures" to which allusion has been already made, and which will be illustrated by examples, and its mode of application pointed out, in another part of the present article.

In certain instances of constant coincidences of structure, as demonstrated by comparative anatomy, the sufficient—*i.e.* recognisable,

[1] *Ossemens Fossiles*, 4to, tom. iii., 1822, p. 1.

Mammalia.

intelligible, or physiological—cause of them is not yet known. But, as Cuvier in reference to such instances truly remarks, "Since these relations are constant, there certainly must be a sufficient cause for them." [1] In certain other cases Cuvier believed that he could assign that "sufficient cause," and he selects as such the correlated structures in a feline Carnivore, and in a hoofed Herbivore. The physiological knowledge displayed by him in his explanation of the condition of those correlations is most exact; its application in the restoration of the *Anoplotherium* and *Palæotherium* most exemplary.

In the ratio of the knowledge of the reason of the coincidences of animal structures—in other words, as those coincidences become "correlations"—is our faith in the soundness of the conclusions deduced from the application of such rational law of correlations; and with the certainty of such application is associated a greater facility of its application. A knowledge of the physiological conditions governing the relations of the contents of the cavities of bones to the flight and other modes of locomotion in birds both enabled the writer to infer from one fragment of a skeleton that it belonged to a terrestial bird deprived of the power of flight, and to predict that such a bird, but of less rapid course than the ostrich, would ultimately be found in New Zealand.[2]

This principle, however,—those modes of thought,—which Cuvier affirmed to have guided him in his interpretation of fossil remains, and which he believed to be a true clue in such researches, were repudiated or contested by some of his contemporaries.

Geoffroy St Hilaire denied the existence of a design in the construction of any part of an organized body; he protested against the deduction of a purpose from the contemplation of such structures as the valves of the veins or the converging lens of the eye.

Beyond the co-existence of such a form of flood-gate with such a course of the fluid, or of such a course of light with such a converging medium, Geoffroy affirmed that thought, at least his mode of thinking, could not sanely. or ought not to go.

The present is not the place for even the briefest summary of the arguments which have been adduced by teleologists and anti-teleologists from Democritus and Plato down to Comte and Whewell. The writer would merely remark, that in the degree in which the reasoning faculty is developed on this planet and is exercised by our species, it appears to be a more healthy and normal condition of such faculty,—certainly one which has been productive of most accession to truths, as exemplified in the mental workings of an Aristotle, a Galen, a Harvey, and a Cuvier,—to admit the instinctive impression of a design or purpose in such structures as the valves of the vascular system and the dioptric mechanism of the eye. In regard to the few intellects,—they have ever been a small and unfruitful minority,—who do not receive that impression and will not admit the validity or existence of final causes in physiology, the writer has elsewhere expressed his belief that such intellects are not the higher and more normal examples, but rather manifest some, perhaps congenital, defect of mind, allied or analogous to "colour-blindness" through defect of the optic nerve, or the inaudibleness of notes above a certain pitch through defect of the acoustic nerve.

The truth of a physiological knowledge of the condition of a correlated structure, and of the application of that knowledge to palæontology, is not affected by instances adduced from that much more extensive series of coincident structures of which the physiological condition is not yet known. Nor is the power of the application of the physiologically interpreted correlation the less certain because the merely empirically recognised coincidences have failed to restore, with the same certainty and to the same extent, an extinct form of animal.

Certain coincidences of form and structure in animal bodies are determined by observation. By the exercise of a higher faculty the reason, or a reason, of these coincidences is discovered, and they become correlations; in other words, it is known not only that they do exist, but how they are related to each other. In the case of coincidences of the latter kind, or of "correlations" properly so called, the mind infers with greater certainty and confidence, in their application to a fossil, than in the case of coincidences which are held to be constant only because so many instances of them have been observed.

Because the application of the latter kind of coincidences is limited to the actual amount of observation at the period of such application, and because mistakes have been made through a miscalculation of the value of such amount, it has been argued that a rational law of the correlation of animal forms is inapplicable to the determination of a whole from a part;[3] and it has not only been asserted that the results of such determination are unsound, but that the philosopher who believed himself guided by such law deceived himself and misconceived his own mental processes![4] But the true state of the case is, that the non-applicability of Cuvier's law in certain cases is not due to its non-existence, but to the limited extent to which it is understood.

The consciousness of that limitation led the enunciator of the law to call the attention of palæontologists expressly to the extent to which it could then be applied, as, for instance, to the determination of the class, but not the order; or of the order, but not the family or genus, &c.; and to caution them also as to the extent of the cases in which, the coincidences being only known empirically, he consequently enjoins the necessity of further observation, and of caution in their induction. Cuvier expresses, however, his belief that such coincidences must have a sufficient cause, and that cause once discovered, they then become correlations and enter into the category of the higher law. Future comparative anatomists will have that great consummation in view, and its result, doubtlessly, will be the vindication of the full value of the law in the interpretation of fossil remains as defined by the illustrious founder of palæontology.

Genus SPALACOTHERIUM, Ow.—The next stratum overlying the older oolites in which mammalian remains have been detected, is a member of the newest oolitic series at Purbeck, Dorsetshire, called the "marly" or "dirt-bed." In a series of fossils discovered there by Mr W. R. Brodie, and transmitted for determination in 1854 to the writer, amongst the remains of fishes and small Saurians, constituting the majority of the specimens, were detected three unequivocal evidences of a mammalian species, which were described under the name of *Spalacotherium*[5] *tricuspidens* The specimen here selected (fig. 85) to exemplify the above extinct insectivorous Mammal, is a right ramus of the lower jaw. The posterior half contains four teeth, and extends backward beyond the dental series; but instead of showing the compound structure which that part of the jaw exhibits in the lizard tribe, it continues undivided; the convex surface showing a smooth depression for the insertion of the temporal muscle; the lower boundary answering to that going to the condyle and angle of the jaw, and the upper one to that going to the coronoid process in the ramus of the jaw of the mole and shrew. The crowns of the teeth are long, narrow, and tricuspid, the inner part of the crown being produced into a point both before and behind the longer cusp which forms the chief outer division of the crown. Each of these teeth is implanted by a fang divided externally into two roots, in a distinct socket in the substance of the jaw. The multicuspid crown, the divided root of the tooth, its complex implantation, and the undivided or simple structure of the ramus of the jaw, all concurred, therefore, to prove the mammalian nature of this fossil.

Fig. 85.

Spalacotherium tricuspidens (twice nat. size), Purbeck beds.

The other specimens showed that the *Spalacotherium* had ten molar teeth in each ramus of the lower jaw, preceded by a small canine and incisors. The anterior molars are compressed, increase in height and thickness to the sixth, and from the seventh decrease in size to the hindmost, which seems to be the last of the series. The sharp multicuspid character of so much of the dental series as is here preserved repeats the general condition of the molar teeth of the small insectivorous Mammalia in a striking degree: one sees the same perfect adaptation for piercing and crushing the tough chitinous cases and elytra of insects. The particular modification of the pointed cusps, as to number, proportion, and relative position, resembles in some degree that of the Cape mole (*Chrysochlora aurea*), but both in these respects and in the number of molars, the dentition accords more closely with that of the extinct *Amphitherium*. The chief interest in the discovery of the *Spalacotherium* is derived from its demonstration of the existence of Mammalia about midway between the older oolitic and the oldest tertiary periods.

Both the Oxford oolitic slate and the Purbeck marly shell-beds give evidence of insect life; in the latter formation abundantly. The association of these delicate Invertebrata with remains of plants allied to *Zamia* and *Cycas*, is indicative of the same close interdependency between the insect class and the vegetable kingdom, of which our power of surveying the phenomena of life on the present

Mammalia.

surface of the earth enables us to recognise so many beautiful examples. Amongst the numerous enemies of the insect class ordained to maintain its due numerical relations, and organized to pursue and secure its countless and diversified members in the air, in the waters, on the earth and beneath its surface, bats, lizards, shrews, and moles now carry on their petty warfare simultaneously, and in warmer latitudes work together, or in the same localities, in their allotted task. No surprise need therefore be felt at the discovery that Mammals and Lizards co-operated simultaneously and in the same locality at the same task of restraining the undue increase of insect life during the period of the deposition of the Lower Purbeck beds.

Genus TRICONODON, Ow.

Sp. *Triconodon mordax*.—This name is proposed for a small zoophagous Mammal, whose generic distinction is shown by the shape of the crowns of the molar teeth of the lower jaw, which consist of three nearly equal cones on the same longitudinal row, the middle one being very little larger than the front and hind cone; and these cones are not complicated by any cingulum or accessory basal cusp. The convex condyle is below the level of the alveoli, and there is no angular process projecting beneath it. The coronoid process is broad and high, with its hinder point not extended so far back as the condyle; the depression marking the insertion of the temporal muscle extends nearly to the lower border of the jaw. There are the obscure remains of three broken incisors, and the point of apparently a canine; next come the two stumps or broken roots of a small premolar; then the crown of a second double-rooted premolar, which show a principal cone and a small anterior cusp; the next tooth is wanting; then there is a larger premolar, with the two fangs raised some way out of their socket: the crown of this tooth shows a principal cone, with a small anterior and large posterior talon; it rises, apparently from partial displacement, higher than the succeeding molars; these are three in number, and present the characteristic three-coned structure already described; each cone is smooth, and convex externally. The three cones seem to answer to the three middle or principal cones of the molars of *Amphilestes* and *Phascolotherium*, but the front and hind cones are raised to near equality with the middle cone in *Triconodon*.

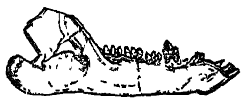

Fig. 86.

Jaw of *Triconodon mordax* (nat. size), Purbeck.

The lower jaw of this species, in the relation of the condyle to the lower border, resembles that of *Phascolotherium* more than that of *Amphitherium*, but it differs from both; there is not the same gradual curve from the condyle to the symphysis as in *Phascolotherium;* and, besides the lower level of the condyle, it is divided by a less deep notch from the coronoid process. This process is larger in proportion to the entire jaw; approaches more nearly to the quadrate or rhomboid form, the upper border being less curved; it affords a more extensive surface of attachment to the principal biting muscles than in most predatory extinct or recent quadrupeds. This character, with the depth and strength of the jaw, suggested the specific name From the shape of the exposed part of the ramus, we may conclude that the part answering to the angle is bent inwards, and that *Triconodon* was a genus of the marsupial order. The specimen was discovered by Mr Beccles in the same "dirt-bed" at Purbeck as that in which *Spalacotherium* was found.

Genus PLAGIAULAX,[1] Fr.—The most remarkable of Mr Beccles' discoveries in the above formation are the mammalian jaws indicative of the genus above named, of which two species have been determined by Dr Falconer.

Sp. *Plagiaulax Becclesii*, Fr.—Two specimens exemplified the

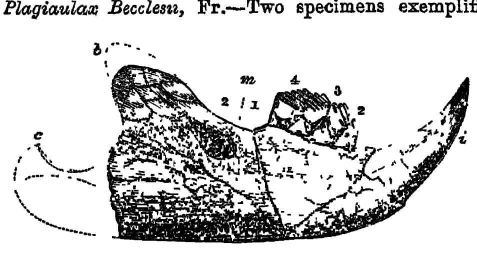

Fig. 87.

Plagiaulax Becclesii (twice nat. size), Purbeck.

shape and proportions of the entire jaw of this species (fig. 87). The foremost tooth (*i*) is a very large one, shaped like a canine, but implanted by a thick root in the fore part of the jaw, like the large lower incisor of a kangaroo or wombat. The three anterior teeth in place have compressed trenchant crowns, and rapidly augment in size from the first (2) to the third (4). They are followed by sockets of two much smaller teeth, shown in other specimens to have subtuberculate crowns resembling those of *Microlestes*. The large front tooth of *Plagiaulax* is formed to pierce, retain, and kill; the succeeding teeth, like the carnassials of Carnivora, are, like the blades of shears, adapted to cut and divide soft substances, such as flesh As in Carnivora, also, these sectorial teeth are succeeded by a few small tubercular ones. The jaw conforms to this character of the dentition. It is short in proportion to its depth, and consequently robust, sending up a broad and high coronoid process (*b*), for the [illegible] grasp of a large temporal muscle, and the condyle (*c*) is placed below the level of the grinding teeth,—a character unknown in any herbivorous or mixed-feeding Mammal; whilst the lever of the coronoid process is made the stronger by the condyle being carried farther back from it than in any known carnivorous or herbivorous animal. The angle of the jaw makes no projection below the condyle, but is slightly bent inwards, according to the marsupial type.

Sp. *Plagiaulax minor*, Fr.—In this species the first premolar (fig. 88, *p*, 1) is preserved, the rest (*p*, 2, 3, and 4) show nearly the same shape and proportions as in *P. Becclesii*. The first molar (*m*, 1) has a broad depression on the grinding surface, surrounded by tubercles, of which three are on the outer border; the marginal tubercles of the second smaller tooth are smaller and more numerous.

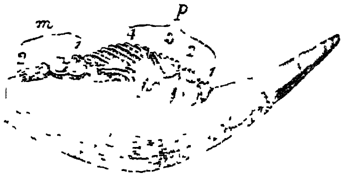

Fig. 88.

Plagiaulax minor (four times nat. size), Purbeck (after Lyell).

In the general shape and proportions of the large premolar (*p*, 4) and succeeding molars, *Plagiaulax* most resembles *Thylacoleo* (fig. 115, *p*, *m*, 1 and 2),—a much larger extinct predaceous Marsupial from tertiary beds in Australia. But the sectorial teeth in *Plagiaulax* are more deeply grooved; whence its name. The single compressed premolar of the kangaroo-rat is also grooved; but it is differently shaped, and is succeeded by four square-crowned double-ridged grinders adapted for vegetable food; and the position of the condyle, the slenderness of the coronoid, and other characters of the lower jaw, are in conformity to that regimen. In *Thylacoleo* the lower canine or canine-shaped incisor projected from the fore part of the jaw close to the symphysis, and the corresponding tooth in *Plagiaulax* more closely resembles it in shape and direction than it does the procumbent incisor of *Hypsiprymnus*. From this genus *Plagiaulax* differs by the obliquity of the grooves on its premolars; by having the analogous teeth vertically grooved; by having only two true molars in each ramus of the jaw, instead of four; by the salient angle which the surfaces of the molar and premolar teeth form, instead of presenting a uniform level line; by the broader, higher, and more vertical coronoid; and by the very low position of the articular condyle.

The physiological deductions from the above-described characteristics of the lower jaw and teeth of *Plagiaulax* are, that it was a carnivorous Marsupial. It probably found its prey in the contemporary small insectivorous Mammals and Lizards, supposing no herbivorous form, like *Stereognathus*, to have co-existed during the upper oolitic period.

In the Woodwardian Museum at Cambridge is a specimen of anchylosed cervical vertebræ of a cetaceous animal as large as a grampus, but presenting specific distinctions from all known recent and fossil species. It is stated to have been found in the brown clay or "till" near Ely; but in its petrified condition, colour, and specific gravity, it is so different from the true bones of the "till," and so closely like the fossils of the Kimmeridge clay, as to make it extremely probable that it has been washed out of that formation.

In a recent visit to Cambridge the writer has identified true cetacean vertebræ which had been discovered associated with bones of *Ichthyosaurus* in the lower greensand (neocomian) near that town. No evidence of the mammalian class has yet been met with in the chalk beds.

The examples of the Mammalia first met with in tertiary strata are the *Coryphodon* and *Palæocyon*, respectively representing the ungulate (herbivorous) and unguiculate (carnivorous) modifications of the class; their remains have been found in the plastic clay and equivalent lignites in England and France.

[1] An abbreviation for *Plagiaulacodon*, from πλάγιος, *oblique*, and αὔλαξ, *groove;* having reference to the diagonal grooving of the premolar teeth.

Mammalia.

Genus CORYPHODON, Ow.—Rarely has the writer felt more misgiving in regard to a conclusion based, in palæontology, on a single tooth or bone, than that to which he arrived after a study of the unique fragment of jaw with one tooth dredged up off the Essex coast, and on which he founded the genus *Coryphodon*.[1]

The marked contraction of the part of the jaw near one end of the tooth seemed, at first view, clearly to show it to be the narrower fore part of the ramus; in that case the tooth would have been a premolar, and of comparatively little value in the determination of a genus or species. But a closer inspection showed the line of abrasion of the summits of the two transverse ridges of the tooth to be on one side, and the general law of the relative apposition and reciprocal action of the upper and lower grinders in tapiroid Pachyderms determined that those oblique linear abrasions must be on the hinder side of the ridges. The smaller characters carried conviction against the showing of the larger and more catching ones. So, in determining the position of the nautilus in its pearly abode, when the animal without its shell was first brought to England in 1831, the reasons afforded by some small and inconspicuous parts in like manner outweighed the first impressions from more obvious appearances, as well as the bias from the general analogies of testaceous Univalves. Some contemporary naturalists asserted, and for a time it was believed, that the nautilus had been put upside down in its shell,[2] just as some contemporary anatomists surmised that the writer had mistaken the fore for the back part of the jaw of his *Coryphœdon*, which, in that case, might only be the known *Lophiodon*. In both instances the conclusions founded on the less obvious characters have proved to be correct. And the writer would remark that, in the course of his experience, he has often found that the prominent appearances which first catch the eye and indicate a conformable conclusion are deceptive, and that the less obtrusive phenomena which require searching out, more frequently, when their full significance is reasoned up to, guide to the right comprehension of the whole. It is as if truth were whispered rather than outspoken by Nature.

Truth, it is sometimes said, lies at the bottom of a well. The first additional glimpse that the writer obtained of the veritable nature of one of our most ancient tertiary Mammals was derived from the inspection of a fossil tooth brought up from a depth of 160 feet, out of the "plastic clay," during the operations of sinking a well in the neighbourhood of Camberwell, near London. It was a canine tooth,[3] belonging, from its size (near 3 inches in length), to a large quadruped, and, from the thickness and shortness of its conical crown, not to a carnivorous but to a hoofed Mammal, most resembling in shape, though not identical with, that of the crown of the canine tooth of some large extinct tapiroid Mammals, which Cuvier had referred to his genus *Lophiodon*, but which has proved to belong to *Coryphodon*.

The last lower molar of *Lophiodon* has three lobes; the molar determined to be the ultimate one, in the fragment of lower jaw above referred to, resembles that of the tapir in the absence of a third or posterior lobe, but the posterior ridge or part of the cingulum is less developed than in the tapir. It presents two divisions in the form of transverse ridges or eminences, the front ridge being the largest, and with its edge most entire. From the outer end of each division a ridge is continued obliquely forward, inward, and downward: the anterior one extends to the antero-internal angle of the base of the crown; the posterior one terminates at the middle of the interspace between the two chief divisions of the crown. The trenchant summit of the anterior ridge is slightly concave toward the fore part of the tooth, as in that of *Lophiodon;* but its outer and inner ends rise higher, and appear as more distinct cones or points; whence the generic name of *Coryphodon*. The posterior division is lower than the anterior one, and is bicuspid; the trenchant margin connecting the outer and inner points does not extend across the crown parallel with the anterior ridge, as in *Tapirus* and *Lophiodon*, but bends back so as to form an angle, the apex of which rises into a third point.

Some lophiodontoid fossils from the lignites of Soissons and Laon, and from the plastic clay of Meudon in France, including the upper molar tooth figured by Cuvier in the chapter of the *Ossemens Fossiles* entitled "Animaux voisins de Tapirs," pl. vii., fig. 6, belong to the genus *Coryphodon*. Cuvier compares this tooth with one from Bastberg, which he figures in pl. vi., fig. 4, and which is certainly the last upper molar of a true *Lophiodon*, and points out truly that the Soissons tooth differs in the external border passing into the posterior one, so that, instead of being quadrangular, its crown is triangular; but he explains this difference on the hypothesis that the Bastberg tooth was a penultimate molar. The reduction of the second or posterior ridge to a semi-circular one, developed at its middle and hindmost part into a prominent cone, so far agrees with the modification of the same part of the last molar of the lower jaw of the *Coryphodon* as to render it very probable that the last upper molar from Soissons, figured by Cuvier in pl. vii., fig. 6, above quoted, also belongs to the genus *Coryphodon*. Cuvier states that the entire skeleton was found, indicative of an animal as long and almost as large as a bull; but that the workmen employed in the sandpit (*sablonière*) preserved only that one tooth. Both the lower molar from Harwich, and the upper one from Soissons, indicate an animal of at least double the size of the American tapir

Mammalia.

Professor Hebert[4] has recently described a very instructive series of teeth and bones from the oldest eocene deposits in France, which he refers to the genus *Coryphodon:* the last molar is identical in form with the tooth from the plastic clay of Essex, on which the genus was originally founded.

Genus PLIOLOPHUS, Ow.—The most complete and instructive example of a Mammal from the next overlying division of the eocene tertiaries, viz., the "London clay," is that which the writer has described[5] under the name of *Pliolophus vulpiceps*. It is a hoofed Herbivore, but presents a dentition not exhibited by any later or existing species of Mammal.

The length of the skull (fig. 89) is 4 inches, its extreme breadth

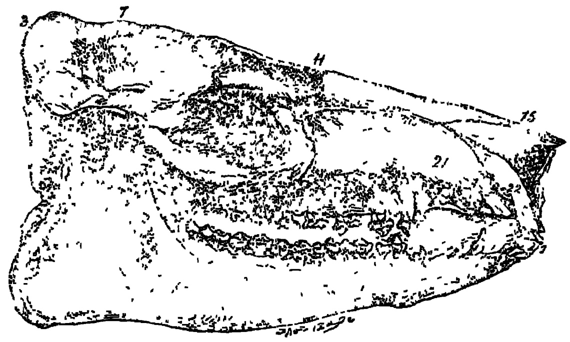

Fig. 89.

Skull of *Pliolophus vulpiceps* (half nat. size), London clay.

2 inches 2 lines, the height of the cranium opposite the first premolar tooth 9 lines. Its shape and characteristics determine the hoofed nature of this species, and its affinities to the Perissodactyla, or the order of Ungulata with toes in odd number. The extent and well-defined boundary of the temporal fossæ by the occipital (3), parietal (7), and post-frontal ridges, and their free communication with the orbits, give almost a carnivorous character to this part of the cranium of *Pliolophus;* but as in the hog, Hyrax, and Palæothere, the greatest cerebral expansion is at the middle and toward the fore part of the fossæ, with a contraction toward the occiput; the brain-case not continuing to enlarge backward to beyond the origin of the zygomata, as in the fox. The zygomatic arches have a less outward span than in the *Carnivora*. In this part of the cranial structure *Pliolophus* resembles *Palæotherium* more than it does any existing Mammal; but the post-frontal processes are longer and more inclined backward. The incompleteness of the orbit occurs in both *Anoplotherium* and *Palæotherium*, as in *Rhinoceros*, *Tapirus*, and the hog tribe; but in the extent of the deficient rim, *Pliolophus* is intermediate between *Palæotherium* and *Tapirus*. The orbit is not so low placed as in *Palæotherium*, *Tapirus*, and *Rhinoceros*, nor so high as in *Hyrax* or *Sus*. The straight upper contour of the skull (7 to 15) is like that in the horse tribe and Hyrax, and differs from the convex contour of the same part in the Anoplothere and Palæothere. The size of the antorbital foramen (*a*) indicates no unusual development of the muzzle or upper lip. In the conformation of the nasal aperture by four bones (two nasals, 15, and two premaxillaries, 22), *Pliolophus* resembles the horse, Hyrax, hog tribe, and Anoplothere, and differs from the rhinoceros, tapir, and Palæothere, which have the maxillaries, as well as the nasals and premaxillaries, entering into the formation of the external bony nostril.

The ungulate and herbivorous character of *Pliolophus* is most distinctly marked by the modifications of the lower jaw, especially by the relative dimensions of the parts of the ascending ramus

Mammalia.

which give the extent of attachment of the biting (temporal) and grinding (masseteric and pterygoid) muscles respectively. In the shape of the mandible *Pliolophus* most resembles *Tapirus* among existing Mammals, and the *Palæotherium* among the extinct ones in which that shape is known. As in almost every species of eocene quadruped yet discovered, the *Pliolophus* presents the type-dentition of the placental diphyodont series, viz.:—

$$i\,\frac{3-3}{3-3},\ c\,\frac{1-1}{1-1},\ p\,\frac{4-4}{4-4},\ m\,\frac{3-3}{—}=44.$$ [1]

The incisors are preserved in the lower jaw with marks of attrition on their crowns demonstrating corresponding teeth of the same number (6), and of similar size, in the upper jaw, from which the alveolar part of the premaxillaries had been broken away.

The canines are small in both jaws: they are separated by a vacant space from the outer incisors, and by a longer interval from the first premolars. These form a continuous series with the remaining teeth in the upper jaw, but are separated by a space of about half their breadth from the second premolar in the lower jaw. The succeeding teeth (*p*, 1, 2, 3, 4) increase in size to the penultimate molar in the upper, and to the last molar in the lower jaw (*p*, 4, in figs. 90 and 91), which tooth has a third lobe.

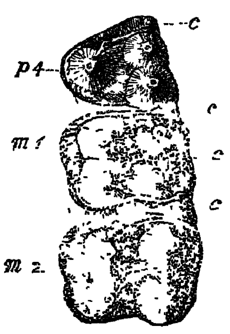

Fig. 90.

True Molars, Upper Jaw (twice nat. size), *Pliolophus*.

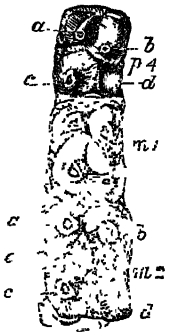

Fig. 91.

True Molars, Lower Jaw (twice nat. size), *Pliolophus*.

In the last premolar upper jaw (fig. 90, *p*, 4) the cingulum is uninterrupted along the outer side from its anterior well-developed talon (*c*) to the back part. The two outer cones resemble those of the true molars; but there is only one inner cone, and the crown of *p*, 4 differs accordingly from that of *m*, 1, in being triangular rather than square. A ridge is continued from the interspace between the anterior talon (*c*), and the outer anterior lobe obliquely inward and backward to the inner lobe, swelling into a small tubercle at the middle of its course.

The first molar (*m*, 1) presents four low thick cones, two internal and two external: each external cone is connected with its opposite internal one by a low ridge, swelling into a tubercle at the middle of its oblique course. The cingulum (*cc*) seems to be continued uninterruptedly round the crown of this tooth, thickest at the fore and back part, and at the interspace of the inner lobes; and developing the small accessory antero-external tubercle. The second molar (*m*, 2) is similar to, but rather larger than, the first; the tubercle on the oblique ridge connecting the two front lobes is less developed. The cingulum is obliterated on the inner side of the posterior lobe.

The last molar is rather narrower behind than *m*, 2; the tubercle on the anterior of the oblique connecting ridges is smaller: that on the posterior ridge is almost obsolete.

In the last lower premolar (fig. 91, *p*, 4) the division and development of the anterior lobe gives rise to a pair of cones, one external (*a*), the other internal (*b*), connected anteriorly by a basal ridge, in front of which is the fore part of the cingulum. The low posterior lobe (*c*) shows the rudiment of a second internal cone (*d*).

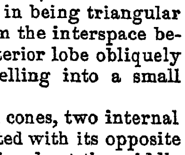

Fig. 92.

True Molar, Lower Jaw (magn.), *Stereognathus ooliticus*.

The first molar (fig. 91, *m*, 1) has a pair of front lobes and a pair of hind lobes, with an oblique ridge continued from postero-internal lobe to the interspace between the front pair.

The second molar (*m*, 2) shows an increase of size; but its chief and most interesting modification is the development of a tubercle (*e*) between the two anterior lobes, making three cones on the same transverse line, and thus repeating the character of the molar tooth of *Stereognathus* (fig. 92, *e*). The oblique ridge from the outer and hinder lobe (*c*) abuts against the intermediate tubercle (*e*). The nearest approach to the above dentition is made by the extinct *Hyracotherium*, also a fossil from the London clay.

The third trochanter on the femur of *Pliolophus*, and the association of three metatarsals in one portion of the matrix, as if belonging to the same hind foot, confirm the essentially perissodactyle affinities of that genus as shown by the skull and teeth. *Pliolophus* and *Hyracotherium* form a well-marked section in the lophiodont family, which seems to have preceded the palæotherian family in the order of appearance, and to have retained more of the general ungulate type than that family. This is shown by the graduation of the tapiroid modification of the molar teeth into one more nearly resembling that of the *Anthracotheria* and *Chœropatami*; by the absence of the postero-internal cone on the ultimate premolar, by which all the premolars are, as in artiodactyles, less complex than the true molars, by the form and position of the nasal bones and the structure of the external nostril.

Genus LOPHIODON, Cuv.—In the year 1800 Cuvier[2] first announced the discovery of the fossil remains of a quadruped allied to and of the size of the tapir, in the lacustrine deposits of the Montagne Noir, near Issel, department of Aude in Languedoc. The outer incisor of the lower jaw was shortened to give room to the longer corresponding incisor above, as in the tapir; the canines offered the same proportional development, but the three first molars (premolars) of the lower jaw presented a more simple structure, having the crown compressed, and forming two cones, the front one being the largest;—in short, a structure, the type of which is presented only by the first of the three premolars (*p*, 2) in the genus *Tapirus*.[3]

Years elapsed ere Cuvier obtained clear evidence of the structure of the upper molars of this new fossil Mammal. Such detached teeth as had been obtained from the fresh-water formations near Issel were referred, owing to the way in which they departed from the type of the upper molar teeth of the *Tapir*, to the genus *Rhinoceros*. This fact is indicative of the annectant affinities of the *Lophiodon* in the perissodactyle series.[4] Besides the character of form, the upper molar series of *Lophiodon* differs, like the lower one, from that in *Tapirus*, in the greater simplicity of the last two premolars; these teeth have a single cone on the inner side in *Lophiodon*; they have there two cones in *Tapirus*, forming the inner terminations of two transverse ridges, as in the true molars. These teeth in the *Lophiodon* differ from those in the *Tapirus* in the greater fore-and-aft expanse of the outer terminations of the transverse ridges, and the less depth of the cleft between them—a more complete coalescence of those parts causing a more entire outer wall of the crown, completes the transition to the Rhinoceros type, towards which the Palæotherium offers the next step.

Genus PALÆOTHERIUM, Cuv.—This extinct genus of quadruped was restored (fig. 93) by Cuvier through a series of admirably instructive steps, ultimately verified by a complete series of fossils, obtained chiefly from the upper eocene gypseous formation at Montmartre and other parts of France. The molar teeth of *Palæotherium* (fig. 94) approach nearer to those of the rhinoceros; but in the number, kind, and general arrangement the entire dentition resembles that of *Pliolophus*. The skull affords indications that the Palæothere possessed a short proboscis. It had three toes on each foot, each terminated by a hoof;

[4] Ibid, p. 470.

the middle one being the largest. The femur had a third trochanter, and the dorso-lumbar vertebræ were 21 in number. Several species of *Palæotherium* have been determined, ranging from the size of a sheep (*P. curtum*) to that of a horse (*P. magnum*). Fig. 94 gives the grinding surface of an upper molar of this species from the upper eocene of the Bembridge beds, Isle of Wight. The crown is divided into an anterior (*b*, *d*) and posterior (*a*, *c*) part by an oblique figure (*e*), continued from near the middle of the inner surface of the crown obliquely across two-thirds of the tooth. Each division is subdivided partially into an outer (*ab*) and an inner (*cd*) lobes; the anterior division, by the terminal expansion (*i*) of the fissure (*e*), the posterior one by the fissure (*g*). The lobes (*c* and *d*) are bordered near their base by a ridge. This is the type of grinding surface, in which are superinduced the modifications of that surface in the upper molars of the rhinoceros and horse.

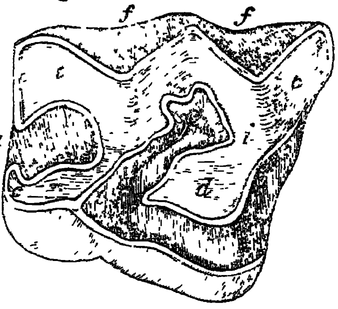

Fig. 94.
Upper Molar, *Palæotherium magnum* (Eocene)

The dental formula of *Palæotherium* is $i\frac{3-3}{3-3}$, $c\frac{1-1}{1-1}$, $p\frac{4-4}{4-4}$, $m\frac{3-3}{3-3}=44$. The canines exceed in length the other teeth and there are consequently vacancies in the dental series for the lodgement of the crowns of the canines when the mouth is shut.

Genus ANOPLOTHERIUM, Cuv.—With the same dental formula as in *Palæotherium*. The present genus, like *Dichodon*, had no interval in the series of teeth; neither the canine nor any other tooth rising above the general level. The grinding surface of the molar teeth somewhat resembles and prefigures the ruminant type; in the upper jaw the crown (fig. 95) is divided into a front (*fc*) and a back (*fd*) lobe by a valley (*e*) extending two-thirds across. A second valley (*gi*) crosses its termination at right angles, forming a curved depression in each division, which it thus subdivides into two lobes, concave towards the outer side of the tooth. There is a large tubercle (*m*) at the wide entry of the valley (*e*). The Anoplothere (fig. 96) was of a lighter and more elegant form than the Palæothere; its limbs terminated each in two digits, with the metapodial bones distinct, and the last phalanx hoofed Some transitory characters of the embryo ruminant were retained throughout life by the Anoplothere. The species restored in fig. 96 was about the size of a fallow-deer it

Fig. 95.
Upper Molar, *Anoplotherium commune* (Eocene Gyps.)

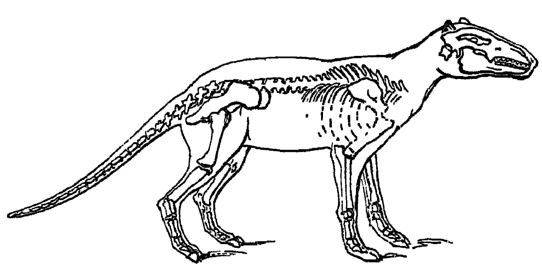

Fig. 96.
Restoration of the *Anoplotherium* (Eocene Gyps.)

had a long and strong tail, and was probably of aquatic habits. Smaller and more delicate species of Anoplotheroids from upper eocene strata have been referred to distinct genera by later palæontologists. The researches of Baron Cuvier, which resulted in the restoration of the *Palæotherium* and *Anoplotherium*, are the most instructive which the palæontologist can study. They form the third volume of the 4to edition of the *Ossemens Fossiles*, 1822–5.

Genus DICHODON, Ow.—The upper eocene beds of Hampshire have yielded evidence of an extinct form of even-toed (artiodactyle) hoofed quadruped, most interesting as a transitional form between the Anoplotheroids and the true Ruminants. Like the *Anoplotherium* the dental series is continuous, without break—a character which is only manifested by mankind among existing Mammals; the crowns of the teeth, in *Dichodon*, being all of nearly equal height, as they are in man. On each side of both upper and lower jaws there are in the *Dichodon* (art. ODONTOLOGY, fig. 118) three incisors (*i*, 1, 2, 3), one canine (*c*), four premolars (*p*, 1, 2, 3, 4), and three true molars (*m*, 1, 2, 3)—in all forty-four teeth, constituting the typical Diphyodont[1] dentition which so many mammalian genera, on their first appearance in the eocene strata, exhibit. It is formalized as follows:—$i\frac{3-3}{3-3}$, $c\frac{1-1}{1-1}$, $p\frac{4-4}{4-4}$ $m,\frac{3-3}{3-3}=44$. From the first incisor to the third premolar the teeth have all a trenchant, and, after the canine, a somewhat trenchant character. The back of the third premolar (*p*, 3), and all the fourth premolar, show the crushing form of crown, which in the true molars, after the wearing down of the first sharp cusps, produces the double crescentic lines of enamel which are now peculiar to the Ruminants amongst hoofed quadrupeds. The extinct species showing the above characters, and on which the genus was founded,[2] was nearly the size of a fallow-deer: it is called *Dichodon cuspidatus*, in reference to the number of sharp points on the unworn molars. The dentition indicates that its food may have been of a peculiar character, perhaps not exclusively of a vegetable nature

In the same upper eocene formation of Hampshire have been found instructive examples of some smaller members of the extinct anoplotheroid family.

Genus DICHOBUNE.—The genus *Dichobune* (from δίχα, *bipartite*; βουνὸς, *collis*) was proposed by Cuvier, in the second edition of his *Ossemens Fossiles*, 4to, tom. iii., 1822, p. 64, for the *Anoplotherium minus* of the original Memoir in the *Annales du Muséum*, tom. iii., 1803, and for the *A. leporinum* of the 4to edition, 1822, tom i., pl. 2, fig. 3; and tom. iii, pp. 70 and 251. It is closely allied to the anoplotherioid genus *Xiphodon;* the dental formula is the same, only there is a slight interval between the canine and the first premolar in both jaws; the first three premolars are subcompressed, subtrenchant, but less elongated from behind forwards than in *Xiphodon*. Besides the two normally-developed and functional digits on each foot, there be one, sometimes two, supplemented digits.

The best illustration of the structure of the upper true molars is afforded by the figure of one of these teeth in the *Proceedings of the Geological Society*, May 20, 1846, published in the *Quarterly Journal*, vol. ii., p. 420. "The anoplotherian character of the tooth is shown by the large size of the lobe (*p*, *x*, fig. 1), and the subgeneric peculiarity by the continuation of its dentinal base with that of the inner and anterior lobe (*id*), at the early stage of attrition presented by the crown of the tooth in question. In the large and typical *Anoplotheria*, the lobe (*p*) preserves its insular form and uninterrupted contour of enamel until the crown is much more worn down than in the present tooth (fig. 1). In this respect, as in the modifications of the lower molar teeth, the genus *Dichobune* shows its closer affinity to the true Ruminants; but the little fold of enamel dividing the lobe *id* from *p* distinguishes the upper molar tooth in question from that of any Ruminant." (P. 421.)

A new and interesting species of this genus, called *Dichobune ovina*, has been founded upon an almost entire lower jaw with the permanent dental series, wanting only the four middle incisors, which now forms part of the palæontological collection in the British Museum. The dental formula, as shown by the mandibular teeth, and by the evidence on their crowns of the presence of the teeth of the upper jaw, is the typical one in diphyodont Mammalia, viz.:—$i\frac{3-3}{3-3}$, $c\frac{1-1}{1-1}$, $p\frac{4-4}{4-4}$, $m\frac{3-3}{3-3}=44$. The canine, with a crown like that of the first premolar, and not longer, is separated from it by an interval of half the breadth of the crown, and by a narrower interval from the outer incisor. The first premolar is divided by an interval of scarce a line's breadth from the second. The rest of the molar series are in contact. The total length of the lower jaw is 5 inches 11 lines ($0^{m}\cdot148$); that of the molar series is 2 inches 11 lines ($0^{m}\cdot075$); that of the three true molars is 1 inch $4\frac{1}{2}$ lines (0^{m} 035). The near equality in height of the crowns of all the teeth, and their general character, show that the animal belonged to the anoplotheroid family. The dentition of the present species differs from that of *Dichodon* in the absence of the accessory cusps on the inner side of the base of the true molars; and both from *Dichodon cuspidatus* and *Xiphodon gracilis* in the minor antero-posterior extent of the premolars; it corresponds with *Dichobune* (as represented by the *D. leporina*, Cuvier) in the proportions of the premolars and in the separation of the canine from the adjoining teeth; to this genus, therefore, the fossil is referable, provisionally, in the absence of knowledge of the molars of the upper jaw, which are the most characteristic; and the writer has proposed to call the

---

[2] *Quarterly Journal of the Geological Society*, tom. iv., 1847, p. 36, pl. 4.

Mammalia.

species, from the size of the animal represented by the fossil, *Dichobune ovina*. It is from Hampshire eocene.

Genus XIPHODON.—The genus *Xiphodon* was indicated, and its name proposed, by Cuvier, for a small and delicate, long and slender-limbed anoplotherian animal, which, in his first Memoir (*Annales du Muséum*, tom. iii., p. 55, 1803), he had called *Anoplotherium medium;* but he altered the name, in the second 4to edition of the *Ossemens Fossiles* (tom. iii., pp. 69 and 251, 1822), to that of *Anoplotherium gracile*.

The distinction indicated by Cuvier is now acccepted by palæontologists as a generic one, and a second species (*Xiphodon Geylensis*) has been added by M. Gervais (*Paléontographie Française*, 4to, 1845, p 90) to the type-species, *Xiphodon gracilis*, of which he figures an instructive portion of the dental series of both jaws, obtained from the lignites of Débruge near Apt. The dental formula of *Xiphodon* is the typical one, viz.:—$i\frac{3-3}{3-3}$, $c\frac{1-1}{1-1}$, $p\frac{4-4}{4-4}$, $m\frac{3-3}{3-3}=44$.

The teeth are arranged in a continuous series in both jaws. The canines and first three premolars have the crowns more extended antero-posteriorly, lower, thinner transversely, and more trenchant, than in the type *Anoplotheria* (whence the name *Xiphodon*, or sword-tooth). The feet are didactyle, with metacarpals and metatarsals distinct. The tail is short. The lower true molars have two pairs of crescentic lobes with the convexity turned outwards.

Genus MICROTHERIUM.—Entire crania of *Microtherium*, from the lacustrine calcareous marls of the Puy-de-Dôme, are in the British Museum, and these show that the hinder division of the upper true molars was complicated by the additional (third) cusp.

With regard to *Microtherium*, the unusually perfect fossil skulls of that small Herbivore, which did not exceed in size the delicate chevrotains of Java and other Indo-Archipelagic islands,—*e.g. Tragulus kanchil*,—are of importance in regard to the question of their alleged affinity to the *Ruminantia*, on account of the demonstration they give of the persistent and functional upper incisor teeth. The little eocene even-toed Herbivores, like the larger Anoplotherioids, thus departed from the characters of the true Ruminants of the present day, in the same degree in which they adhered to the more general type of the artiodactyles Had M. de Blainville, who believed them to be Ruminants, possessed no other evidence of the *Microtherium* than of the *Dichobune murina* and *Dichobune obliqua*, Cuv., he would have had the same grounds for referring the *Microtheria*, as the *Dichobunes*, to the genus *Tragulus* or *Moschus* (les Chevrotains); but the entire dentition of the upper jaw of the species *Anoplotherium murinum* and *A. obliquum*, referred by Cuvier to his genus *Dichobune*, must be known before the existence of Ruminants in the upper eocene gypsum of Paris can be inferred.

No doubt the affinity of these small Anoplotheroids to the Chevrotains was very close. Let the formative force be transferred from the small upper incisors to the contiguous canines, and the transition would be effected. We know that the Ruminant stomach of the species of *Tragulus* is simplified by the suppression of the psalterium or third bag. The stomach of the small Anoplotheroids, whilst preserving a certain degree of complexity, might have been somewhat more simplified. The certain information which the gradations of dentition displayed by the above-cited extinct species impart, testifies to the artificial character of the order *Ruminantia* of the modern systems, and to the natural character of that wider group of even-toed hoofed animals for which has been proposed the term ARTIODACTYLA.[1]

Genus HYÆNODON, Laiz.—With the delicate and beautiful Herbivora of the upper eocene and lower miocene periods, there coexisted carnivorous quadrupeds, which, to judge by the character of their flesh-cutting teeth (carnassials), were more fell and deadly in their destructive task than modern wolves or tigers. Of these old extinct Carnivora a species of the remarkable genus *Hyænodon*, of about the size of a leopard, has left its remains in the upper eocene of Hordwell, Hampshire. Fig. 113, art. ODONTOLOGY (vol. xvi., p. 464), shows the dentition of the under jaw of another species of the same genns from miocene beds at Débruge and Alais, France. The carnassial teeth (*m*, 1, 2, 3), instead of being one in number in each ramus of the jaw, as in modern Felines, were three in number, equally adapted by their trenchant shape, to work like scissor-blades on the teeth of the upper jaw, in the act of cutting flesh. After the small incisors came a pair of large piercing and prehensile canines (*c*), followed by four compressed pointed and trenchant premolars (*p*, 1, 2, 3, 4) in each side of the jaw; the whole of this carnivorous dentition conforming to the diphyodont type:—

$$i\frac{3-3}{3-3},\ c\frac{1-1}{1-1},\ p\frac{4-4}{4-4},\ m\frac{3-3}{3-3}=44.$$

Genus AMPHICYON.—With the foregoing predecessor of the digitigrade Carnivora was associated a forerunner of the plantigrade family, viz., a large extinct species having the molars tuberculated, after the pattern of those of the bears; but retaining, like *Hyænodon*, the perfect type of diphyodont dentition. Fig. 114, art. ODONTOLOGY (vol. xvi., p. 464), shows the teeth of one side of the upper jaw of the *Amphicyon giganteus* The first and second molars (*m*, 1 and 2) have each two tubercles on the outer side and one on the inner side; the last tubercular molar (*m*, 3) is of very small size. Fossil remains of *Amphicyon* have been found principally in the miocene deposits at Sansans, south of France. Those of a smaller species from the miocene at Epplesheim, have been referred to the wolverine genus as *Gulo diaphorus*, Kaup.

Mammalia.

The proofs of the abundant mammalian inhabitants of the eocene continent were first obtained by Cuvier from the fossilized remains in the deposits that fill the enormous Parisian excavation of the chalk. But the forms which that great anatomist restored were all new and strange, specifically, and for the most part generically distinct from all known existing quadrupeds. By these restorations the naturalist was first made acquainted with the aquatic cloven-hoofed Anoplothere, and with its light and graceful congeners, the Dichobunes and Xiphodon, with the great Palæotheres, which may be likened to hornless rhinoceroses, with the more tapiroid Lophiodon, with the large peccari-like Pachyderm called Chœropotamus, and with about a score of other genera and species of placental Mammalia.

Almost the sole exception to the generic distinction of these eocene forms from modern ones was yielded by the opossum of Montmartre (*Didelphis Gypsorum*, fig. 97); and what made this discovery the more remarkable was the fact that all the known existing species of that marsupial genus are now confined to America, and the greater part to the southern division of that continent. An opossum appears to have been associated with the peccari-like Hyracotherium in the eocene sand of Suffolk; where likewise, a porcine beast with tusks like ordinary canines (*Chœropotamus*), and some remains of a monkey (*Eopithecus*), have been found. With respect to the *Didelphis Gypsorum*, its generic relations were deduced from characters of the lower jaw and teeth; but these were associated with other parts of the skeleton in the same block of stone. When Cuvier expressed his convictions from the teeth and other parts first exposed and examined, his scientific associates were incredulous. He invited them, therefore, to witness a crucial test. The outline of the back part of the pelvis was exposed, the fore part buried in the matrix. By his delicate use of the graving-tool, Cuvier brought to light the fore-part of the pelvis with the two marsupial bones (fig. 97, *a*, *a*) in their natural position. He thus demonstrated that there had been buried in the soft fresh-water deposits, hardened in after ages into the building-stone of Paris, an animal whose genus at the present day is peculiar to America. It is not uninteresting to remark that the Peccari, the nearest existing ally to the old Chœropotamus, is, like the opossum, now peculiar to America; and that two species of tapir, the nearest living allies to the Lophiodon and Palæothere, exist in South America.

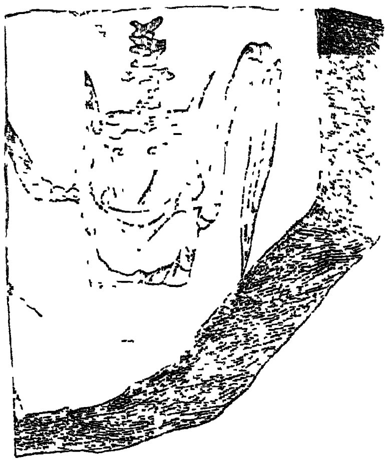

Fig. 97.

Pelvis and Marsupial Bones of *Didelphis Gypsorum* (Eocene, Paris).

The marine deposits of the miocene epoch show the remains of extinct genera of dolphins (*Ziphius* and *Dioplodon*) and of whales (*Balænodon*). Petrified cetaceous teeth and ear-bones, called "cetotolites" (fig. 98) have been washed out of previous strata into the red crag of Suffolk. These fossils belong to species distinct from any known existing Cetacea, and which, probably, like some contem-

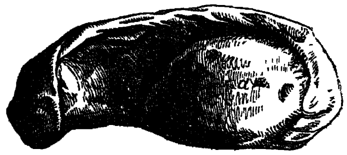

Fig. 98.

Cetotolite or Fossil Ear-bone of *Balænodon gibbosus* (Red Crag, Suffolk).

[1] *Quarterly Journal of the Geological Society*, vol. iv., 1847.

Mammalia. porary quadrupeds, retained fully-developed characters which are embryonic and transitory in existing cognate Mammals. The teeth of these Cetacea were determined in 1840, the ear-bones in 1843. The vast numbers of these fossils, and the proportion of phosphate of lime in them, led Professor Henslow[1] to call the attention of agricultural chemists to the red crag as a deposit of valuable manure. Since that period it has yielded a large supply, worth many thousand pounds annually, of the superphosphates. The red crag is found in patches from Walton-on-Naze, Essex, to Aldbro', Suffolk, extending from the shore to 5 or 15 miles and more inland. It averages in thickness 10 feet, but is in some places 40 feet. Broken-up septarian nodules form a rude flooring to the crag, left by the washing off of the London clay, and called "rough stone." The phosphatic fossils, or "cops," as they are now locally termed, occur in greatest abundance immediately above the "rough-stone." Thousands of cubic acres of earlier strata must have been broken up to furnish the cetacean nodules of the "red crag." This is a striking instance of the profitable results of a seemingly most unpromising discovery in pure science,—the determination of what in 1840 was regarded as a rare, unique, and most problematical British fossil.[2]

Our knowledge of the progression of mammalian life during the miocene period is derived chiefly from continental fossils. These teach us that one or two of the generic forms most frequent in the older tertiary strata still lingered on the earth, but that the rest of the eocene Mammalia had been superseded by new forms, some of which present characters intermediate between those of eocene and those of pliocene genera. The *Dinotherium* and narrow-toothed *Mastodon*, for example, diminish the interval between the *Lophiodon* and the elephant; the *Anthracotherium* and *Hippohyus*, that between *Chœropotamus* and *Hippopotamus*; the *Acerotherium* was a link connecting *Palæotherium* with *Rhinoceros*.

One of the most extraordinary of the extinct forms of the cetaceous order has been restored from fossil remains discovered in formations of the miocene age in Europe and North America. The teeth of this carnivorous whale, for which the generic name *Zeuglodon* seems now to be generally accepted, were first described and figured by the mediæval palæontologist Scilla, in his treatise entitled *De Corporibus Marinis* (4to, 1747, tab. xii., fig. 1), and have since given rise to various interpretations. The originals were obtained from the miocene strata at Malta, and are now preserved in the Woodwardian museum at Cambridge.

The remains of a gigantic species of the same genus, discovered by Dr Harlan in miocene formations of Arkansas, Mississippi, were described and figured by him as those of a reptile, under the name of *Basilosaurus*.[3] Teeth of a smaller species, discovered by M. Grateloup, in miocene beds of the Gironde and Herault, were ascribed by him also to a reptile, under the name of *Squalodon*.[4] In 1839 Dr Harlan brought over his specimens of *Basilosaurus* to London, and submitted them to the writer's inspection, by whom they were determined to be mammalian and cetaceous. The entire skeleton has since been obtained from miocene deposits in Alabama, revealing a length of body of about 70 feet. The skull is very long and narrow; the nostril single, with an upward aspect, above and near the orbits. The jaws are armed with teeth of two kinds, set wide apart; the anterior teeth have sub-compressed, conical, slightly-recurved, sharp-pointed crowns, and are implanted by a single root; the posterior teeth are larger, with more compressed and longitudinally extended crowns (see fig. 65, art. ODONTOLOGY), conical, but with a more obtuse point, and with both front and hind borders strongly notched or serrated. The crown is contracted from side to side in the middle of its base, so as to give its transverse section an hour-glass form (see fig. 66, ODONTOLOGY), and the opposite wide longitudinal grooves which produce this form become deeper as the crown approaches the socket, where they meet and divide the root into two fangs. The name *Zeuglodon* (yoke-tooth) refers to this structure. The mode of succession of the teeth in this genus conforms to the general mammalian type more than does that of any of the existing carnivorous Cetaceans. In the figure given by Dr Carus[5] of a portion of the jaw of *Zeuglodon cetoides*, a deciduous molar (fig. 65, *a*, ODONTOLOGY) is about to be displaced and succeeded, vertically, by a second larger molar. This mode of succession is not known in the *Platanista* or *Inia*, which among existing true Cetacea present teeth most like those of *Zeuglodon*; but it is a mode of succession and displacement affecting certain teeth in the herbivorous Cetacea, or *Sirenia*; and we thus seem to have in the *Zeuglodon* another of those numerous instances of a more generalized character of organization in older tertiary Mammalia. In systematic characters, *Zeuglodon* typifies a distinct family or group, intermediate between *Cetacea* proper and *Sirenia*. Mammalia.

Of the latter family or order, however, represented at the present day by the Dugongs, Manatees, and Stellerians or Arctic Manatees (if the species still survives), there were abundant and more widely distributed representatives during the miocene period, having, upon the whole, the nearest affinity with the existing African Manatee (*Manatus Senegalensis*), but with associated characters of the Dugong (*Halicore*). There were, *e.g.*, two incisive tusks in the upper jaw, and four or five small incisors along the deflected part of each ramus of the lower jaw. The upper molars, with three roots, were thickly enamelled, like those of the Manatee, but with a pattern of grinding surface which led Cuvier to attribute detached specimens to a small species of *Hippopotamus*. The lower molars had two roots. All the bones have the dense or solid structure of those of the *Sirenia*. On the remains of this remarkable amphibious Mammal, discovered by Kaup in 1838, in the miocene beds at Eppelsheim, he founded the genus *Halitherium*. Other remains have been discovered in Piedmont, Asté, and many parts of France, from the "calcaire grossier" of the Gironde, containing Lophiodont fossils, up to the pliocene near Montpellier; at which period the *Halitherium* seems to have become extinct.

Genus MACROTHERIUM, Lartet.—The edentate order, which is so abundantly and variously represented in South America, which has its Orycteropes and Pangolins in Africa, and its Manises in tropical Asia, has no living representative in Europe. Perhaps the most unexpected form of Mammal to be revealed by fossil remains from European tertiary deposits, after a Marsupial, was a member of the edentate order. Cuvier, by whom the evidence of this extinct animal was first made known, prefaces his description of the single mutilated phalangeal bone, on which that evidence was founded, by the remark, that "nothing proves better the importance of the laws of comparative osteology than all the consequences which one may legitimately draw from a single fragment." One willingly admits the proof so afforded of the former existence of animals now unknown; but one may demur to the conclusion that their extinction was due to some sudden catastrophe.

The single mutilated ungual phalanx on which Cuvier based his conclusions in regard to the species in question was discovered, associated with remains of *Rhinoceros*, *Mastodon*, *Dinotherium*, and *Tapir*, in a formation near Eppelsheim, Hesse-Darmstadt, which is now determined to belong to the miocene division of the tertiary series. This phalanx shows two distinctive characters of the edentate order:—*1st*, Its posterior surface for articulation with the antepenultimate phalanx is a double pulley, hollowed out on each side, with a salient crest between, constituting the firm kind of ginglymoid joint peculiar to certain *Edentata*; *2d*, The concave arch formed by that pulley curves furthest backward at its upper part, which would prevent the claw being retracted upward, as in the cat tribe, and constrain the flexion downward—"ainsi c'est necessairement un onguéal d'edenté."[6] To the foregoing characters are joined two others which Cuvier believed to determine "as necessarily" the genus. The species of *Myrmecophaga* have on the upper part of the pointed end of the claw-phalanx a groove, indicative of a disposition to bifurcate; in the species of *Manis* the bifurcation is complete, the cleft extending as far as the middle of the claw-bone. The Pangolins (*Manis*) have not those bony sheaths, which, in the sloths, some ant-eaters and armadillos, rise from the base and cover the root of the claw; there was a like absence of any claw-sheath in the fossil. Thus the fossil claw-bone has no homologue in existing nature save those of the Manis; and, "according to all the laws of co-existence, it is impossible to doubt that the most marked relations of the animal that bore it should have been with that genus of quadrupeds."[7] But what must have been its size? The phalanx was not one of the largest on the foot —for it had not those slight raised borders which one sees in the large claw-bones of the Pangolins. This question, which Cuvier answered by the proportions of the short-tailed Manis, at 24 French feet, has had a more reasonable reply given to it by certain other bones of the skeleton subsequently discovered in the miocene tertiaries of France. These discoveries have likewise rectified and moderated the absolute application of the correlative law to the necessary determination of the genus as well as of the order. The relations of the double-jointed and cleft phalanx to the Edentata is beautifully confirmed; but the additional fossils, and especially some evidences of teeth, have shown that it belonged to a peculiar and now extinct genus intermediate between the *Manis* and the *Orycteropus*. And these relations are deeply interesting on account of the geographical position of both those edentate genera, on

Mammalia.

tracts of land, viz., which are now most contiguous to the continent containing the remains of the extinct osculant genus.

The locality in France is near the village of Sansan, near Auch, department of Gers, Haute-Pyrenées. The formation is a lacustrine deposit of the miocene period.

Portions of two molar teeth have been found, 1 inch 8 lines in greatest transverse diameter; the tooth preserving the same size and shape through the whole length of the portion—viz., 1½ inch. They resemble in shape those of the Orycterope, but are less regular and have not the same tubular tissue. Their microscopic texture appears not to have been analysed; it would be important to determine whether it resembled that of the teeth of the sloths or armadillos. The humerus differs from that of the ant-eaters and armadillos by its greater length in proportion to its breadth, and by the peculiar flattening from before backwards of its lower half, and especially at the condyles, above which it is expanded transversely by both external and internal supra-condyloid ridges. It is not perforated above the inner condyle, as the same bone is in both the *Manis* and *Orycteropus*. In the degree to which it departs from the type of the ant-eaters it approaches that of the Megatheroids and sloths—viz., in its relative length, flattening at the distal end, and the imperforate character of that end. The radius also presents a sloth-like character in its greater proportionate length, which exceeds that of the humerus; and in the compression of its lower slightly-expanded end. In both the Pangolin and Orycterope the radius is shorter than the humerus. The ulna differs likewise from both that of the Pangolin and Orycterope, and still more from that in the Armadillos by the much smaller development of the olecranon, whereby, again, it more resembles that of the sloths. The femur is relatively longer and more slender than that of the terrestrial and fossorial Edentata; it has not the third trochanter which characterizes it in the Orycterope, nor so marked a development of the great and small trochanters as in the Pangolin. In the flattened form of the shaft of the femur, and the position of the rotular surface near one side of the distal end, it resembles the femur of the Megatherium and Mylodon. It is shorter than the humerus; whereas, in both the Pangolin and Orycterope the femur is longer: in this respect the femur of the Macrothere resembles that of the sloths. The great width of the popliteal space dividing the condyles is an endentate and more especially a megatheroid character. The internal condyle is much broader than the external one, as it likewise is in the Megatheroids; it is certainly with the femur of the latter family of the Edentata, rather than with that of the Proboscidians or Pachyderms, that one should compare the femur of the Macrothere: it is not so long or so slender relatively as in the sloths. The tibia is much shorter than the femur, and in the expansion of its proximal end and its relative length to the femur it resembles that of the Megatheroids more than that in the Pangolin or Orycterope; it was not anchylosed to the tibia as in the Armadillos, Glyptodons, and Megatherium, but a distinct bone, as in the Mylodon and sloths.

Genus PLIOPITHECUS, Gerv.—In the same miocene deposits of the south of France as those which contained the *Macrotherium*, fossil remains of two kinds of Quadrumana, resembling a small and large species of *Hylobates*, have been discovered. The smaller of these extinct apes, called *Pliopithecus antiquus* by Gervais, is based upon the lower jaw and dentition. The teeth occupy an extent of 1½ inch; the two incisors are narrower, the canine less, and the last molar is larger than in the siamang (*H. syndactyla*). As in this species the first premolar is uni-cuspid, and the hind talon of the second is more produced than in the chimpanzee and gorilla, and to the degree in which the fore-and-aft diameter of the tooth exceeds the transverse one, it departs farther from the human type; in the degree of the development of the talon or third lobe of the last lower molar, the *Pliopithecus* resembles the tailed monkeys (*Semnopithecus* and *Innus*).

Genus DRYOPITHECUS, Lart.—In the larger miocene ape (*Dryopithecus Fontani*, Lart.) the canine is relatively larger than in the *Hylobates*, and the incisors, to judge by their alveoli, are relatively narrower than in the chimpanzee and human subject. The first premolar has the outer cusp pointed, and raised to double the height of that of the second premolar, and its inner lobe is more rudimental than in the chimpanzee,[1] and departs proportionally from the human type. The posterior lobe or talon of the second premolar is more developed, and the fore-and-aft extent of the tooth greater, than in the chimpanzee, thereby more resembling the second premolar of the siamang, and less resembling that of the human subject. The last (third) molar is undeveloped in the fossil jaw of the *Dryopithecus*, and its amount of departure from the human type, and approach to that of *Innus*, cannot be determined. The canine is more vertical in position than in *Troglodytes* or *Pithecus*, but this character is offered by some of the small South American apes, and cannot be cited as a mark of real affinity. From the portion of humerus associated with the jaw of *Dryopithecus*, the arm would seem to have been proportionally longer and more slender than in the chimpanzee and gorilla, more like that in the long-armed apes (*Hylobates*), and less like the arm of the human subject.

Mammalia.

The characters of the nasal bones, orbits, mastoid processes, relative length of upper limb to trunk, relative length of arm to fore arm, relative length and size of thumb, relative length of lower limb, and, above all, the size of the hallux and shape of the astragalus and calcaneum, must be known before any opinion can be trusted as to the proximity of *Dryopithecus* to the human subject.

Genus MESOPITHECUS Wagn.—In tertiary formations of Greece, at the base of Pentelicon, remains of a Quadrumane have been found, which Professor Wagner[2] regards as transitional between *Hylobates* and *Semnopithecus*: the third lobe of the last molar is, however, as well developed as in the latter genus.

In the pliocene deposits of Montpellier remains of a monkey occur, referred by Christol to a *Cercopithecus*; and in pliocene brick-earth in Essex the writer has determined part of the fossil jaw and teeth of a *Macacus*.

Genus DINOTHERIUM, Cuv. and Kp.—This name was given by Kaup to the huge bilophodont Mammal, first made known by Cuvier under the name of "Tapir gigantesque," after the discovery of the singular shape and armature of the lower jaw. The length of the skull, from *f* to *d*, in fig. 99, is 3 feet 8 inches. The teeth

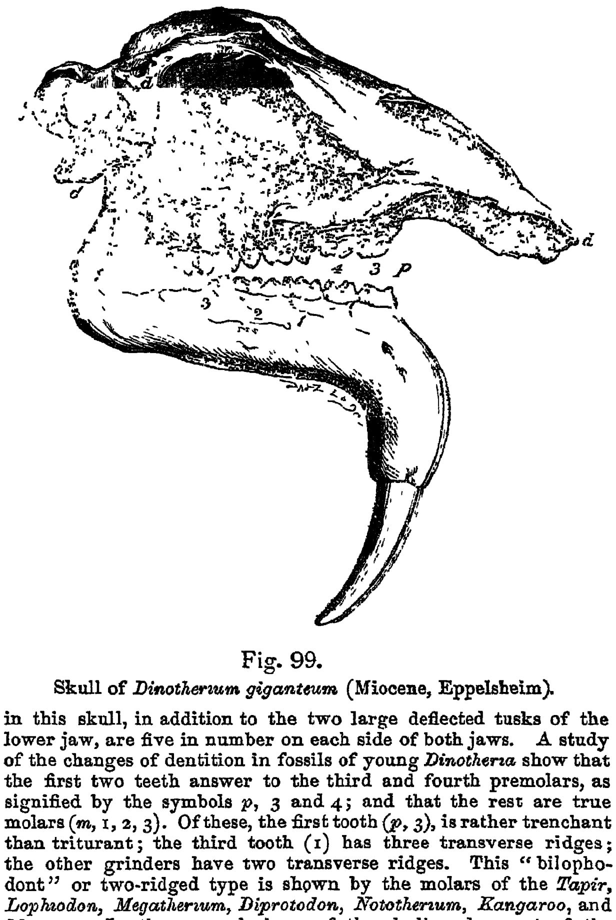

Fig. 99.

Skull of *Dinotherium giganteum* (Miocene, Eppelsheim).

in this skull, in addition to the two large deflected tusks of the lower jaw, are five in number on each side of both jaws. A study of the changes of dentition in fossils of young *Dinotheria* show that the first two teeth answer to the third and fourth premolars, as signified by the symbols *p*, 3 and 4; and that the rest are true molars (*m*, 1, 2, 3). Of these, the first tooth (*p*, 3), is rather trenchant than triturant; the third tooth (1) has three transverse ridges; the other grinders have two transverse ridges. This "bilophodont" or two-ridged type is shown by the molars of the *Tapir*, *Lophiodon*, *Megatherium*, *Diprotodon*, *Nototherium*, *Kangaroo*, and *Manatee*. In the general shape of the skull and aspect of the nostrils *Dinotherium* most resembles *Manatus*. Bones of limbs have not yet been found so associated with teeth as to determine the ordinal affinities of *Dinotherium*. Yet cranial and dental evidences of the genus have been discovered in miocene deposits of Germany, France, Switzerland, and Perim Island, Gulf of Cambay.

Genus MASTODON, Cuv.—The earliest appearance of this genus of proboscidian or elephantoid Mammal is in tertiary strata of miocene age, and by a species in which the fore part of the lower

[1] Compare *Comptes Rendus de l'Acad. des Sciences*, tom. xliii. (July 28, 1856, plate, fig. 7), with *Trans. Zool. Soc.*, vol. iv., plate 32, fig. 3, p. 3.

Mammalia.

jaw was produced into a pair of deep sockets containing tusks; but these are only slightly deflected from the line of the grinding teeth (fig. 100, *C*). This species of *Mastodon*, discovered in the miocene of Eppelsheim, was called *longirostris* by Kaup, but he afterwards recognised it as the same with a species which had been previously called *Mastodon arvernensis* (Croizet and Jobert)[1] Both belong to that section of *Mastodon* in which the first and second true molars have each four transverse ridges,[2] and for which Dr Falconer proposes the name *Tetralophodon*. In the newer tertiary deposits of North America remains of a Mastodon (*M. Ohioticus*) have been discovered, in which the transverse ridges of the grinders are in shape more like those of the Dinothere than in any other Mastodon; the first and second, moreover, are bilophodont, the third trilophodont; but this is followed by two three-ridged molars and a last larger molar with four or five ridges.[3] For the Mastodons with penultimate and antepenultimate grinders with three ridges, Dr Falconer proposes the name *Trilophodon*. In the *Mastodon Ohioticus* the lower jaw has two tusks in the young of both sexes, these are soon shed in the female, but are long retained by the male (fig. 100, *B*). The upper tusks are long and retained in both sexes (fig. 100, *A*).[4]

An almost entire skeleton of a Mastodon (*M. turicencis*) has been discovered in the pliocene deposits of Asté, Piedmont, and has been described and figured by Professor Sismonda,[5] from whose beautiful Memoir fig. 100 is taken. The total length, from the tail to the end of the tusks, is 17 feet. The teeth have the same narrow shape and multi-mammillate structure as in *M. arvernensis*, but in the numerical character of transverse divisions of the crown this species agrees with *M. Ohioticus*. The Mastodons were elephants with the grinding teeth less complex in structure, and adapted for bruising coarser vegetable substances. The genus was represented by species ranging, in time, from the miocene to the upper pliocene deposits, and in space, cosmopolitan with tropical and temperate latitudes. The transition from the mastodontal to the elephantine type of dentition is very gradual.

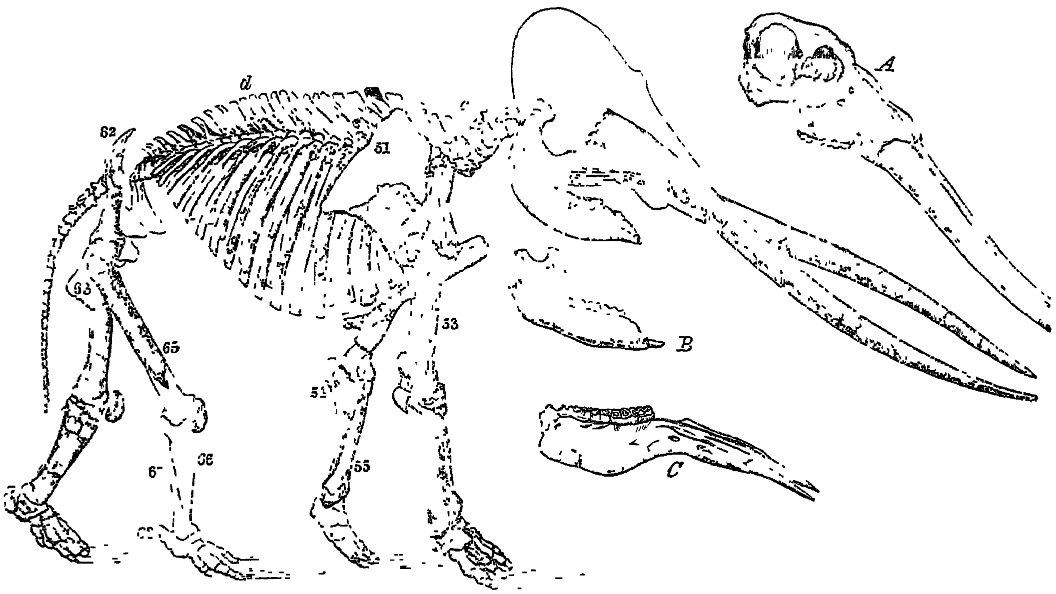

Fig. 100.

Mastodon turicencis (Pliocene): *A, B.*—*M. Ohioticus*; *C.*—*M. longirostris.*

Genus ELEPHAS, L.—The latest form of true elephant which obtained its sustenance in temperate latitudes is that which Blumenbach called *primigenius*, the "Mammoth" of the Siberian collectors of its tusks (fig. 101). Its remains occur chiefly, if not exclusively, in pleistocene deposits, and have even been found in turbary near Holyhead. Its grinders are broader, and have narrower and more numerous and close-set transverse plates and ridges, than in other elephants.[6] The mammoth is more completely known than most other extinct animals by reason of the discovery of an entire specimen preserved in the frozen soil of a cliff at the mouth of the river Lena in Siberia. The skin was clothed with a reddish wool, and with long black hairs. It is now preserved at St Petersburg, together with the skeleton (fig. 101). This measures, from the fore part of the skull to the end of the mutilated tail, 16 feet 4 inches; the height, to the top of the dorsal spines, is 9 feet 4 inches; the length of the tusks, along the curve, is 9 feet 6 inches. Parts of the skin of the head, the eye-ball, and of the strong ligament of the nape which helped to sustain the heavy head and teeth, together with the hoofs, remain attached to the skeleton. These huge elephants, adapted by their clothing to endure a cold climate, subsisted on the branches and foliage of the northern pines, birches, willows, &c.; and during the short summer they probably migrated northward, like their contemporary the musk-buffalo, which still lingers on, to the 70th degree of N. latitude, retreating during the winter to more temperate quarters. The mammoth was preceded in Europe by other species of elephant,—*e.g.*, *Elephas meridionalis* (Nesti), which, during the pliocene period, seem not to have gone northward beyond temperate latitudes. An elephant, hardly distinguishable from the African, also roamed at that period in Europe.[7]

Genus HIPPOPOTAMUS, L.—The discovery, in lacustrine and fluviatile deposits of Europe, of the remains of an amphibious genus of Mammal now restricted to African rivers, gives scope for speculating on the nature of the land which, uniting England with the Continent, was excavated by lakes and intersected by rivers, with a somewhat warmer temperature than at present, to judge by a few S. European shells which occur in the fresh-water formations,—*e.g.*, at Grays, Essex, where remains of the large extinct *Hippopotamus major* have been found. The specimen of lower jaw (fig. 102) was discovered in similar deposits on the Norfolk coasts. Other localities are specified in the writer's *History of British Fossil Mammals*.

The hippopotamus is first met with in pliocene strata. The remains of *H. major* have hitherto been found only in Europe; they are common along the Mediterranean shore, and do not occur north of the temperate zone. In Asia this form of Pachyderm was represented, perhaps at an earlier period, by the genus *Hexaprotodon*,—essentially a hippopotamus, with six incisor teeth, instead of four, in each jaw.

Genus RHINOCEROS, L.—The rhinoceros, like the elephant, was represented in pliocene and pleistocene times, in temperate and northern latitudes of Asia and Europe, by extinct species. One

named fossil rhinoceroses were two-horned; but they were preceded, in the pliocene and miocene periods, by species devoid of horns, yet a rhinoceros in all other essentials (*Acerotherium*, Kaup). Not fewer than twenty species of extinct rhinoceroses are entered in Palæontological catalogues.

Order RUMINANTIA.

Of other forms of beasts subsisting on the vegetable productions of the earth, and more akin to actual European Herbivora, there co-existed with the foregoing now exotic genera a vast assemblage of species, nearly all of which have passed away. The quadrupeds called "Ruminants," from the characteristic second mastication of the partly-digested food by the act called "rumination" or "chewing the cud," constitute at the present period a circumscribed group of Mammalia, which Cuvier believed to be "the most natural and best-defined order of the class."[2] He characterized it as having incisive teeth only in the lower jaw (fig. 107, *c*), which were replaced in the upper jaw by a callous gum. Between the incisors and molars is a diastema, in which, in certain genera only, may be found one or two canines. The molars (fig. 107, *h*), almost always six on each side of both jaws, have their crown marked by two double crescents, with the convexity turned inwards in the upper set, outwards in the lower.[3] The four legs are terminated by two toes and two hoofs, flattened at the contiguous sides, so as to look like a single hoof cloven; whence the name "cloven-footed," also given to these animals. The perfect circumscription and definition of this order, so desirable by the systematic zoologist, is indeed invaded, in the actual *Ruminantia*, by certain peculiarities of the camel tribe.

In entering upon the evidences of the first appearance in this planet of the order of animals, which now are the most valuable to man, it may be well to call to mind the characters of the *Anoplotherium*. The upper true molars have two double crescents, convex inwards, one of the inner ones being encroached on by a large tubercle, the reduced homologue of which may be seen in the internal interspace of the crescents in the ox and some other Ruminants. The lower true molars also, at one stage of attrition, form crescentic islands of enamel, with the convexity turned outwards, as in Ruminants, the last molar having the accessory crescent behind. The functional hoofs were two in number on each foot, but must have resembled those of the camel tribe in shape; the scaphoid and cuboid of the tarsus were distinct also, as in the *Camelidæ;* and the metacarpal and metatarsal bones were divided, as in the water musk-deer (*Moschus aquaticus*), and in the embryos of all Ruminants. The dentition of the extinct Dichodon[4] made a still nearer approach to that of the Ruminants. The chief distinction of this and other extinct Herbivores with double crescentic molars is the completion of the upper series of teeth by well-developed incisors. But the premaxillaries in the new-born camel contain each three incisors, one of which becomes fully developed. The *Camelidæ* are hornless, like the Anoplotherioids and Dichodonts, and with one exception—the giraffe—all Ruminants are born without horns.

Thus the *Anoplotherium*, in several important characters, resembled the embryo Ruminant, retaining throughout life those marks of adhesion to a more generalized mammalian type. The more modified or specialized form of hoofed animal, with cloven foot and ruminating stomach, appears at a later period.

Family I.—Bovidæ.

Fossil molars of the ruminant type and bovine character have hitherto been found, with unequivocal evidence, to the writer's knowledge, only in beds or breccias of pliocene and pleistocene age.

[1] 4to, 1793, pp. 130–132. [2] *Règne Animal*, tom. i., p. 254. [3] See art. Odontology, p. 466, figs. 120, 121.
[4] See art. Odontology, p. 465, fig. 118.

Mammalia.

At those periods in Britain there existed a very large species of bison (*Bison priscus*), and a larger species of ox (*Bos antiquus*), from pliocene fresh-water beds; whilst a somewhat smaller but still stupendous wild ox (*B. primigenius*) has left its remains in pleistocene marls of England and Scotland. With this was associated an aboriginal British ox of much smaller stature and with short horns (*B. longifrons*), which continued to exist until the historical period, and was probably the source of the domesticated cattle of the Celtic races before the Roman invasion. A buffalo, not distinguishable from the musk kind (*Bubalus moschatus*), now confined to the northern latitudes of North America, roamed over similar latitudes of Europe and Asia in company with the hair-clad elephants and rhinoceroses.

FAMILY II.—CERVIDÆ.

Cuvier[1] first made known the fact of teeth with the character of ruminant molars, and of portions of antlers, being associated with

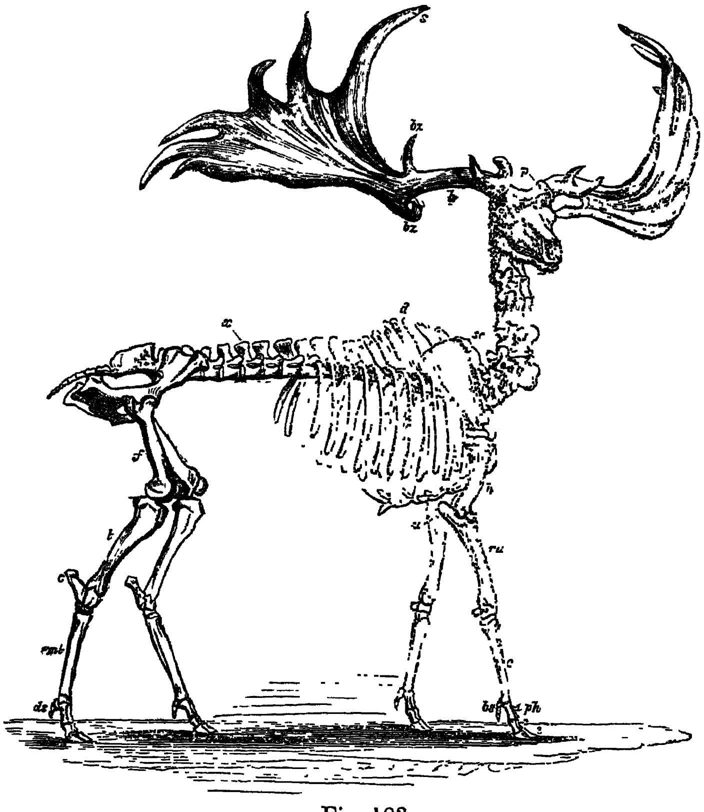

Fig. 103.

Megaceros Hibernicus (Pleistocene marl).

emains of *Lophiodon* and *Mastodon* in the fresh-water miocene beds of Montabusard, department of the Loiret. These early ruminant fossils agreed in size with the roebuck; but there were characters showing that they differed almost generically from all known deer. In 1834 Professor Kaup received from the miocene strata near Eppelsheim, Darmstadt, the entire cranium of a small Ruminant, the teeth of which were identical with those described and figured by Cuvier; but, the series being complete, showed that the animal had long procumbent canines, as in the *Moschus moschiferus*; in some secondary characters of the teeth, however, as in the proportions of the premolars, and especially the presence of the first of that series, at least in the lower jaw, it was generically distinct from *Moschus* or *Tragulus*. Moreover, the animal had possessed, like the males of the small deer of India called "Muntjac," antlers as well as long canine teeth. Both in the miocene beds of Ingré and Eppelsheim, antlers have been found which were supported on long pedicles, as in the muntjac, and simply bifurcate near their end. It is probable that these horns, which have been referred to the nominal species *Cervus anocerus*, may belong to the *Dorcatherium* of Kaup.

Other species of *Cervidæ* were, however, associated with that remarkable form in the miocene period. Dr Kaup ascribes some more or less mutilated antlers, which had been shed, to a species he calls *C. dicranocerus*. The beam rises from 1 to 2 inches without sending off any branch or brow-antler; it then sends off a branch so large and so oblique that the beam seems here to bifurcate; the anterior prong is, however, the smallest and shortest. The writer has received similar shed and mutilated antlers from the red crag of Sussex, which seems to contain a melange of broken-up beds of eocene, miocene, and pliocene age.[2]

The cervine Ruminants have been divided into groups according to the forms of the antlers. Of the group with antlers expanded and flattened at top, of which the fallow-deer (*Dama*) is the type, no fossil examples have been found in Britain. Cuvier has described and figured antlers of great size from the pliocene deposits of the valley of the Somme, near Abbeville, which, from the relative position and direction of the brow-snag and mid-snag, and from the terminal palm, he regards as a large extinct species of fallow-deer; the name *Cervus Somonensis* has since been attached to this species. But there once existed a group (*Megaceros*, fig. 103) characterized by a form of antler at present unknown amongst existing species of deer. With a beam (*b*) expanding and flattening towards the summit, and a brow-snag (*p*), as in the *Dama* tribe, this antler shows a back-snag (*bz*). Moreover, in antlers which, from their size and form, seem to have been developed by the deer at its prime, the brow-snag expands and sometimes bifurcates,—a variety never seen in the fallow-deer, but which becomes exaggerated in the reindeer group. The representative of the present *Megaceros* is one extinct species (*M. Hibernicus*, fig. 103), remarkable for its great size, and especially for the great relative magnitude and noble form of its antlers: it is the species commonly but erroneously called the "Irish elk;" because it is a true deer, intermediate between the fallow- and rein-deer; and because, though most abundant in, it is not peculiar to, Ireland. In that country it occurs in the shell-marl underlying the extensive turbaries. In England its remains have been found in lacustrine beds, brick-earth, red clay, and ossiferous caves.[3]

The reindeer (*Cervus Tarandus*) has peculiar antlers (fig. 104), and proportionably the largest of any of existing species. The beam is somewhat flattened throughout, but expands only and suddenly at its extremity, a similar expansion characterizing the brow-snag (*br*) and mid-snag (*bz*), two, three, or more points being developed from all these expansions in fully-developed antlers. The brow-snag is remarkable for its length. There is also frequently a short back-snag. It is plain, therefore, from the presence of this snag, from the great relative size of the antlers, from the complex brow-snag, and the terminal expansion of the beam, that we have in the reindeer the nearest of kin to the extinct *Megaceros*.

The existing species (*Tarandus*) is restricted to northern latitudes, ranging to extreme ones in Europe, and in America from the Arctic Circle southward to the latitude of Newfoundland, where the large variety called "Carabou" still exists. Reindeer of similar size ranged over continental Europe, appear to have been seen by Cæsar in Germany, and have left good evidence of their existence in many parts of England. The specimen figured (fig. 104) was found in pleistocene "till" at Bilney Moor, East Dereham.

A large deer, with subcompressed ramified antlers, slightly expanding at the base of the terminal divisions, but differing from the reindeer in the absence of the brow-snag, has left its remains in the pleistocene sands of Riège, near Pézenas, France. It is the *Cervus martialis* of Gervais; and seems to have been an intermediate form between the reindeer (*Tarandus*) and the elk (*Alces*). There is no existing representative of this interesting annectant form of deer.

In formations of corresponding age in France, called "alluvions volcaniques" by Gervais,[4] fossil antlers of two other extinct species of deer have been discovered, in which, as in *Alces*, the brow-antler is absent, but in which the beam does not expand into a palm.

In North America remains of a large deer (*Cervus americanus fossilis*, Harlan), much resembling the *Wapiti* (*Cervus canadensis*) have been found in pleistocene deposits on the banks of the Ohio. In South America Dr Lund discovered fossil antlers of two species in bone-caves in Brazil: they were associated with remains of an antelope (*Antilope maquinensis*, Lund) of which genus no living representative is now known in South America.

Skull and Antlers of *Cervus Tarandus.*

which rivalled the *Megaceros* in bulk (*Strongyloceros spelæus*); and with this are found, in similar places of deposit, remains of a red-deer with antlers equalling or surpassing the finest that have been observed within the historical period.

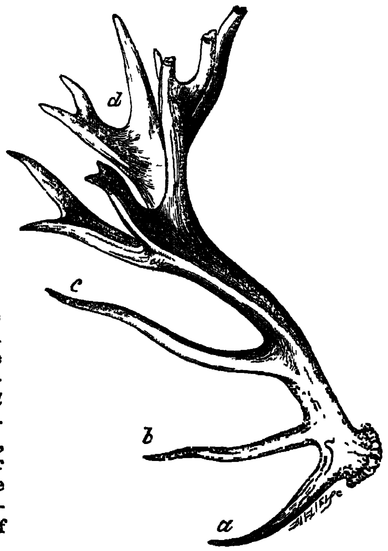

Fig. 105.

Antler of Red-deer, from alluvium, Ireland.

Fig. 105 represents one of a pair of antlers from the bed of the Boyne at Drogheda, now in the museum of Sir Philip Egerton, Bart., which measures 30 inches in length, and sends off not fewer than fifteen branches or "snags." *a* is the "brow-snag," which rises immediately above the "burr;" *b* the second, *c* the third, and *d* the "crown" or terminal cluster of snags, which gave to the deer developing them at the period of his full perfection the title of "crowned hart."

The little roebuck, like the red-deer, appears from its fossil remains to have continued to exist from the prehistorical pleistocene times to the present period.

ORDER CARNIVORA.

The quadrupeds which subsist by preying upon others co-existed under corresponding varieties of form, and in adequate numbers, with the numerous and various *Herbivora* of the newer tertiary periods. A brief description has already been made of some of the singular forms, the genera of which are extinct, that lived in eocene and miocene times.

Genus GALECYNUS, OW.—In 1829 the fossil skeleton of a Carnivore, of the size of a fox, was discovered by Sir Roderick I. Murchison in the pliocene schist of Œningen. On a close comparison of this specimen, the writer finds that the first premolar is smaller, and the third and fourth larger than in the fox, and all the teeth are more close-set and occupy a smaller space than in the genus *Canis;* the bones of the feet are more robust; and these, with other characters, indicate an extinct genus intermediate between *Canis* and *Viverra*.[1] The unique specimen is now in the British Museum.

Mammalia.

Genus FELIS, L.—As it is by this form of perfect Carnivore that Cuvier chiefly illustrated his principle of the correlation of animal structures, it will be exemplified more particularly in this place, and by the aid of the subjoined cut (fig. 106). The founder of palæontology thus enunciates the law which he believed to be so operative in his labours of re-constructing extinct species:—

"Every organized being forms a whole, a single circumscribed system, the parts of which mutually correspond and concur to the same definitive action by a reciprocal re-action. None of these parts can change without the others also changing, and consequently each part, taken separately, indicates and gives all the others."[2]

Cuvier did not predicate that law by an *à priori* method, by any of those supposed short cuts to knowledge, the fallacy of which Bacon so well exposes; he arrived at the law inductively, and after many dissections had revealed to him the facts—of the jaw of the Carnivore being strong by virtue of certain proportions; of its having a peculiarly shaped and articulated condyle, with a plate of bone of breadth and height adequate for the implantation of muscles, with power to inflict a deadly bite—a process grasped by muscles of such magnitude as necessitated a certain extent of surface for their origin from the cranium, with concomitant strength and curvature of the zygomatic arch; the facts of the modified occiput and dorsal spines in relation to vigorous uplifting and retraction of the head when the prey had been griped; the size and shape of the piercing, lacerating, and trenchant teeth; the mechanism of the retractile claws, and of the joints of the limb that wielded them:—it was not until after Cuvier had recognised these facts, and studied them and their correlations in a certain number of typical *Carnivora*, that he felt justified in asserting that "the form of the tooth gives that of the condyle, of the blade-bone (*s*), and of the claws, just as the equation of a curve evolves all its properties; and exactly as, in taking each property by itself as the base of a particular equation, one discovers both the ordinary equation and all its properties, so the claw, the blade-bone, the condyle, the femur, and all the other bones individually, give the teeth, or are given thereby reciprocally; and in commencing by any of these, whoever possesses rationally the laws of the organic economy will be able to re-construct the entire animal." The principle is so evident that the non-anatomical reader will have little difficulty in satisfactorily comprehending it by the aid of the subjoined diagram.

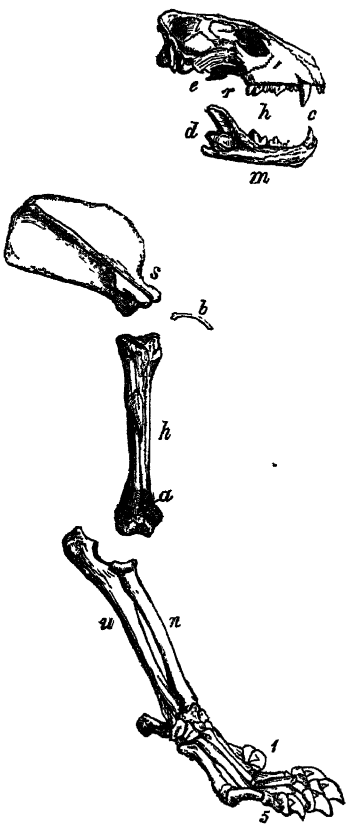

Fig. 106.

Palæontological characters of a Feline Carnivore.

In the jaws of the lion (fig. 106), there are large pointed teeth (laniaries or canines, *c*) which pierce, lacerate, and retain its prey. There are also compressed trenchant teeth (*h*), which play upon each other like scissor-blades in

[1] See *Quarterly Journal of the Geological Society*, vol. iii., 1647, p. 55.

[2] *Ossemens Fossiles*, 4to, tom. i. (1812), p. 58.

the movement of the lower upon the upper jaw. The lower jaw (*m*) is short and strong; it articulates to the skull by a transversely extended convexity or condyle (*d*), received into a corresponding concavity (*e*), forming a close-fitting joint, which gives a firm attachment to the jaw, but almost restricts its movements to one plane, as in opening and closing the mouth. The plate of bone, called coronoid process (*r*), which gives the surface of attachment to the chief biting muscle (crotaphyte or temporal) is broad and high; the surface on the side of the skull (temporal fossa, *t*) from which that muscle arises is correspondingly large and deep, and is augmented by the extension of ridges of bone from its upper and hinder periphery.

The bar or bridge of bone (zygomatic arch) which spans across the muscle, bends strongly outwards to augment the space for its passage; and as it gives origin to another powerful biting muscle (masseter), the arch is also bent upwards to form the stronger point of resistance during the gripe of that muscle. From almost all the periphery of the back surface of the skull there is a strong pitted ridge, affording extensive attachment to powerful muscles which raise the head, together with the animal's body, which the lion may have seized with his jaws; this beast of prey being able to drag along the carcase of a buffalo, and with ease to raise and bear off the body of a man. If we next examine the framework of the fore limb, which is associated with the above-defined structure of the skull, we find that the fore paw consists of five digits (1–5), the innermost and shortest (1) answering to our thumb, and having two bones; the other four digits having each three bones or "phalanges." All those digits enjoy a certain freedom of motion and power of reciprocal approximation for grasping; but their chief feature is the modification of the terminal phalanx, which is enlarged, compressed, subtriangular and more or less bent; with a plate of bone as it were, reflected forwards from that base, from which the pointed termination of the phalanx projects like a peg from a sheath. A powerful, compressed, incurved, sharp-pointed, hard, horny claw is fixed upon that peg, its base being firmly wedged into the interspace between the peg and the sheath. The toe-joint so armed is retractile. This complex, prehensile, and destructive paw is articulated to the two bones of the fore leg (radius, *n*, and ulna, *u*); they are both strong, are both distinct, are firmly articulated to the arm-bone (*h*) by a joint, which, although well built, allows great extent and freedom of motion in bending and extension; and, besides this, the two bones are reciprocally joined so as to rotate on each other, or rather the radius upon the ulna, carrying with it, by the greater expansion of its lower end, the whole paw, which can thus be turned "prone" or "supine;" whereby its application as an instrument for seizing and tearing is greatly advantaged. The humerus or arm-bone (*h*) is remarkable for the extension of strong ridges from the outer and inner sides, just above the elbow-joint. These ridges indicate the size and force of the supinator, pronator, flexor, and extensor muscles of the paw. To defend the main artery of the fore leg from compression during the action of these muscles, a bridge of bone (*a*) spans across it as it passes near their origin. The upper end of the arm-bone is equally well marked by powerful ridges for muscular implantation, especially for the deltoid; but these ridges do not project beyond the round "head" of the bone, so as to impede its movements in the socket.

The blade-bone (scapula, *s*) is of great breadth, with well-developed processes (spine, acromion, and coracoid) for muscular attachments; the size and shape of this bone relate closely to the volume of the muscles which operate upon the arm-bone and fore limb. A small clavicular bone (*b*) is interposed between a muscle of the head and one of the arm, giving additional force and determination of action reciprocally to both muscles.

Such are some of the modifications of the teeth and framework of a beast of prey, which concur, and were deemed by Cuvier to be correlated, in the organization of such animals

Let us compare them with those of the corresponding parts in an ox (fig. 107). The teeth answering to the great laniaries in the lion are absent; at most, one recognises the homologues of the lower canines, reduced in size and altered in shape, so as to form the outer teeth (*c*) of a bent row of incisors terminating the lower jaw. The back teeth (*h*), instead of being trenchant, have broad and flat crowns, roughened with hard ridges, opposing each other with a grinding action, like mill-stones. The lower jaw is long and slender; it articulates to the skull by a flat condyle (*d*), admitting of rotatory movements upon a flattened articular surface on the skull, and limiting the extent of opening and shutting the mouth. The coronoid process (*r*) is very slender, and the fossa which marks the size of the temporal muscle (*t*) is correspondingly small. The zygomatic arch (*o*) is short and feeble, and its span is narrow; it is almost straight, or with a slight bend downwards. The part of the skull (pterygoid plates), which afford attachment to the rotating muscles of the jaw, and the (angular) part (*f*) of the jaw into which they are inserted, are of great extent. The ox masticates grass with great efficiency; it inflicts no injury to other animals with its teeth. The horns are its weapons, and they are chiefly defensive.

The fore foot of the ox is reduced to two principal toes, with two rudimentary ones dangling behind. Each of these has its extremity enveloped by a thick horny case, or hoof, this modification is accompanied by a junction or coalescence of the radius (*n*) and ulna (*u*), preventing reciprocal rotation or movement of those bones on each other,—by a joint restricting the movement of the fore arm (antibrachium) upon the arm (brachium or humerus, *h*) to one plane,—by a long and narrow blade-bone (*s*), with a stunted coracoid and no clavicle; in short, by modifications adapting the limb to perform the movements required for locomotion, and almost restricting it to such. This type of fore limb is always associated with broad grinding teeth, and with the modifications of jaw and skull above defined. The due amount of observation assured Cuvier that these several modifications, like the contrasted ones in the Carnivora, were correlated, and he enumerates the physiological grounds of that correlation.

Fig. 107.

Palæontological characters of a Ruminant (*Bos*).

Those grounds may be traced to a certain degree in the secondary modifications of the ferine order. If the retractibility of the claw be suppressed, the carnassiality of the teeth is reciprocally modified. If the unguiculate foot is reduced from the digitigrade to the plantigrade type, the dentition is still more altered, and made more subservient to a mixed diet.

By the application of the correlative principle to the fossil mammalian remains of pliocene and later deposits, the Herbivora have been distinguished from the Carnivora; and out of the latter have been re-constructed extinct species of the feline, viverrine, ursine, and other families of the order. In England and continental Europe a peculiarly destructive feline quadruped existed, with the upper canines much elongated, trenchant, sharp-pointed, sabre-shaped; whence the name *Machairodus* proposed for this feline sub-genus. It was represented by species as large as a lion (*M. cultridens* and *M. latidens*); and by others of the size of a leopard (*M. palmidens* and *M. megantereon*). This form is first found in the miocene of Auvergne and of Eppelsheim; next in the pliocene of the Val d'Arno; and finally in cave breccia in Devonshire.

The finest examples of the large pleistocene lion (*Felis spelæa*) have been discovered in bone-caves,—*e.g.*, in those of Banwell, Somersetshire, and of Belgium. The production of the apex of the nasal process of the maxillary, as far back as that of the nasal bone, proves this species to have been a lion, not a tiger. It roamed over pliocene and pleistocene Europe, and has left its remains in many stratified deposits of the former period in Britain. Under similar circumstances have been found, more abundantly in Germany, the remains of the gigantic bear (*Ursus spelæus*), and more abundantly in England those of the great hyæna (*Hyæna spelæa*), probably a spotted one, like the fierce "Crocuta" of the Cape. Wolves, foxes, badgers, otters, wolverines, and martin-cats, foumarts and weasels, have left their remains in the newer tertiary deposits and bone-caves. Bats, moles and shrews were then, as now, the forms that preyed upon the insect world in Europe. The majority of these Carnivora, like the hares, rabbits, voles, and other Rodents, are not distinguishable from the species which still exist. These smaller unguiculate Mammals, like the smaller pleistocene

Mammalia.

Ruminants, seem to have survived those changes during which the larger species perished. It is probable that the horse and ass are descendants of a species of pleistocene antiquity. At the pliocene period there existed a species similar in size to a zebra. There is no certain character by which the present wild boar can be distinguished specifically from the *Sus*, which was contemporary with the mammoth.

Order Rodentia.

The small size of the great majority of the species of this order leads to the neglect or the oversight of their fossil remains by the labourers in quarries and other deposits of stone, to whom the palæontologist is usually indebted for his first acquaintance with characteristic fossils of such formations. No evidence has yet been obtained of any unequivocal remains of a rodent animal in strata more ancient than the eocene tertiary deposits. Cuvier detected remains of Rodents allied to the dormouse (*Myoxus*) and squirrel (*Sciurus*) in the building-stone of the Montmartre quarries near Paris. The lacustrine marls of the middle (miocene) tertiary period have yielded evidences of not fewer than eleven genera of Rodentia distinct from any now known to exist. The deposits at Eppelsheim, near Darmstadt, of the same miocene age have given evidence of Rodents akin to the marmot and the beaver. The more recent tertiary formations and the bone-caves in England have furnished fossil remains not distinguishable from the existing beaver, hare, and rabbit, water-vole and field-vole, as well as remains of a Pica, or tailless hare, belonging to the genus *Lagomys*, now confined, as an existing species, to Asia; and of a very large Rodent, akin to the beaver, called *Trogontherium* Similar fossil remains have been abundantly found in the pliocene and pleistocene formations of continental Europe; whilst the coeval deposits of America have yielded fossil remains of extinct species belonging to genera,—*e g.*, *Lagostomus*, *Echimys*, *Ctenomys*, *Cœlogenys*, and other Cavies,—now restricted to South America. In North America, fossil remains of a Rodent of comparatively gigantic size have recently been discovered. Some parts of the skeleton, and more especially the dentition of the rodent order, are highly characteristic,—the form of the articular surface for the lower jaw, which is a longitudinal groove, the molars, especially of the phytiphagous kinds, crossed by enamel plates more or less transverse,—these, with the long, curved, chisel-shaped incisors, two in each jaw, suffice to determine the ordinal relations of the fossil. The incisors alone would not be always so safe a guide, for the rodent modification of these teeth is repeated in the marsupial wombat and the lemurine aye-aye.[1]

With regard to the Rodentia, the great beaver (*Trogontherium*) seems to have become extinct in England and the Europæo-Asiatic continent before the historical period, whilst the smaller pliocene beaver continued to exist with us like the wolf, until hunted down by man. It still survives in a few of the great continental rivers. Of the little Lagomys of our ossiferous caves no living example remains in either England or Europe. The species, indeed, may be extinct: its genus is now limited to Central and Southern Asia.

Geographical Distribution of Pleistocene Mammals.

A most interesting generalization has been educed from the mass of facts relating to the fossil Mammals of the later tertiaries,—viz., their close correspondence between the fauna of those and present periods in the Europæo-Asiatic expanse of dry land. For here species continue to exist of nearly all those genera which are represented by pliocene and post-pliocene mammalian fossils of the same natural continent and of the immediately adjacent island of Great Britain.

The bear has its haunts in both Europe and Asia; the beaver of the Rhone and Danube represents the great Trogontherium; the Lagomys and the tiger exist on both sides of the Himalayan mountain chain; the hyæna ranges through Syria and Hindostan; the bactrian camel typifies the huge *Merycotherium* of the Siberian drift; the elephant and rhinoceros are still represented in Asia, though now confined to the south of the Himalayas. The true macacques are peculiar to Asia, and though most abundant in the southern parts of the continent and the Indian Archipelago, also exist in Japan; a closely-allied sub-genus (*Innus*) is naturalized on the rock of Gibraltar at the present day. A fossil species of Macacus was associated with the elephant and rhinoceros in England during the period of the deposition of the newer pliocene freshwater beds. The more extraordinary extinct forms of Mammalia, called *Elasmotherium* and *Sivatherium*, have their nearest existing pachydermal and ruminant analogues in the same continent to which those fossils are peculiar. Cuvier places the Elasmothere between the horse and rhinoceros: the existing four-horned antelopes, like their gigantic extinct analogues, the Sivathere and Bramathere, are peculiar to India. It may be regarded as part of the same general concordance of geographical distribution, that the genus *Hippopotamus*, extinct in England, in Europe, and in Asia, should continue to be represented in Africa, and in none of the remoter continents of the earth,—Africa also having its hyæna, its elephant, its rhinoceroses, and its great feline Carnivores. The discovery of extinct species of *Camelopardalis* in both Europe and Asia, of which genus the sole existing representative is now, like the hippopotamus, confined to Africa, adds to the propriety of regarding the three continuous continental divisions of the Old World as forming, in respect to the geographical distribution of pliocene, post-pliocene, and recent mammalian genera, one great natural province. The only large edentate animal (*Pangolin gigantesque*, Cuvier, *Macrotherium*, Lartet) hitherto found in the tertiary deposits of Europe, manifests its nearest affinities to the genus *Manis*, which is exclusively Asiatic and African.

Extending the comparison between the existing and the latest of the extinct series of Mammalia to the continent of South America, it may be first remarked that, with the exception of some carnivorous and cervine species, no representatives of the above-cited mammalian genera of the Old World of the geographer have yet been found in South America. Buffon[2] long since enunciated a similar generalization with regard to the existing species and genera of Mammalia; it is almost equally true in respect of the fossil. Not a relic of an elephant, a rhinoceros, a hippopotamus, a bison, a hyæna, or a lagomys, has yet been detected in the caves or the more recent tertiary deposits of South America. On the contrary, most of the fossil Mammalia from those formations are as distinct from the Europæo-Asiatic forms as they are closely allied to the peculiarly South American existing genera of Mammalia.

The genera *Equus*, *Tapirus* and the still more ubiquitous *Mastodon* form the chief, if not sole exceptions. The representation of *Elephas* during the pliocene period by distinct species in Asia (*E. primigenius*) and in South America (*E. curvidens*), is analogous to the geographical distribution of the species of *Tapirus* at the present day.

South America alone is now inhabited by species of sloth, of armadillo, of cavy, aguti, ctenomys, and platyrrhine monkey; but no fossil remains of a quadruped referable to any of these genera have yet been discovered in Europe, Asia, or Africa. The types of *Bradypus* and *Dasypus* were, however, richly represented by diversified and gigantic specific forms in South America during the geological periods immediately preceding the present. The skeleton of one of these forms of the sloth tribe is represented in fig. 108;

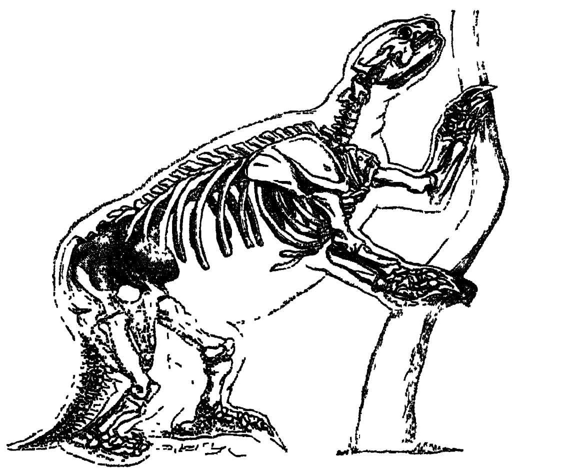

Fig. 108.

Extinct Terrestrial Sloth, *Mylodon robustus* (Pleistocene, S America).

it measures, from the fore part of the skull to the end of the tail, 11 feet. It was discovered buried 12 feet deep in the fluviatile deposits seven leagues north of the city of Buenos Ayres in the year 1841. It forms the subject of a work entitled *Description of the Skeleton of an Extinct Gigantic Sloth (Mylodon robustus)*,[3] in which are set forth in detail the grounds for regarding it as a member of the same natural family as the present small arboreal sloth, and as being modified to obtain its leafy food by uprooting and prostrating trees.

A still larger species of terrestrial sloth co-existed with the Mylodon in South America. Its skeleton, now complete in the British Museum, measures 18 feet; its dentition agrees as to number and kind of teeth with that of the sloths (*Bradypus*). But the

[3] 4to, 1842, Van Voorst.

molars (fig. 109) are longer, more deeply implanted, of more complex structure, and with grinding surfaces of the bilophodont type. The elephants, which subsist on similar food to that of the Megatherium, had their grinding machinery maintained by a numerous

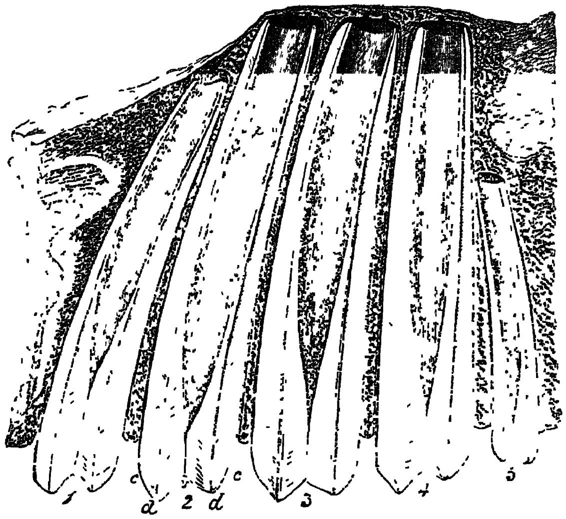

Fig. 109.

Section of Upper Molar Teeth, *Megatherium* (one-third nat. size), Pleistocene, South America.

succession of teeth. The same end was attained in the Megatherium, by a constant growth and renovation of the same teeth. The formative pulps were lodged in the deep basal cavities, exposed in the section figured (fig. 109). The molar teeth were five in number on each side of the upper jaw, and four in number on each side of the lower jaw (fig. 110). In this bone the fore part is much prolonged, and grooved above, to support a long, cylindrical, powerfully muscular tongue, by which, like the giraffe, the Megatherium stripped off the small branches of the trees its colossal strength enabled it to prostrate. The dentition of *Mylodon* differed only from that of *Megatherium* in the shape of the teeth. The same may be said of the allied genera called *Megalonyx* and *Scelidotherium*. They were contemporary and geographically associated genera of the same, now quite extinct, family of great terrestrial sloths.

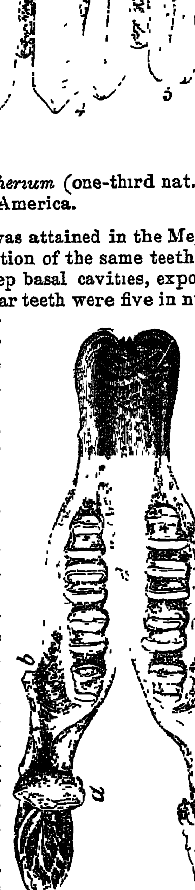

Fig. 110.

Lower Jaw and Teeth of *Megatherium* (Pleistocene, South America).

In like manner, the small loricated and banded quadrupeds of South America called armadillos were represented in pleistocene times in South America by as well-defended species, rivalling the Megatherioids in bulk. The specimen of the almost entire skeleton and bony armour (fig. 111) is one of the smaller species of these great extinct non-banded armadillos, yet it measures from the snout to the end of the tail, following the curve of the back, 9 feet; the tesselated trunk-armour being 5 feet in length and 7 feet across, following the curve at the middle of the back. These large extinct species differ from the modern armadillos, in having no bands or joints in their coat of mail, for the purpose of contracting to a ball. They also differ in the fluted form of the teeth (fig. 112); whence the generic name (*Glyptodon*) assigned to them. The species are distinguished, like their puny representatives (*Dasypus*), by peculiar patterns of the outer surface of the constituent ossicles of the tesselated mail. In the species figured (*G. clavipes*), a large raised central circular plate is surrounded by smaller portions. The species named *G. reticulatus*, *G. tuberculatus*, *G. ornatus*, &c., have their names from other modifications of the sculptured surface of their armour. Above the principal figure in cut 111 are shown the front and back margins of the body-armour; below it, opposite the left hand, are upper

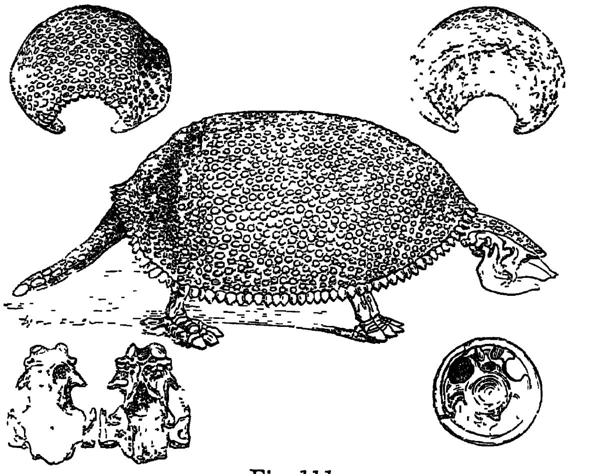

Fig. 111.

Extinct gigantic Armadillo.

and under views of the cranium, which was defended by a tesselated bony casque. The tail also had its independent osseous sheath, supported by the vertebræ within, as shown in the figure opposite the left hand.

Other evidences of extinct South American Mammals, matched only by species now peculiar to that continent, might be adduced if space permitted.

Fig. 112.

Teeth of great extinct Armadillo (*Glyptodon clavipes*), Pleistocene, South America.

Australia in like manner yields evidence of an analogous correspondence between its last extinct and its present aboriginal mammalian fauna, which is the more interesting on account of the very peculiar organization of most of the native quadrupeds of that division of the globe. That the Marsupialia form one great natural group, is now generally admitted by zoologists; the representatives in that group of many of the orders of the more extensive placental sub-class of the Mammalia of the larger continents have also been recognised in the existing genera and species: the dasyures, for example, play the parts of the *Carnivora*, the bandicoots (*Perameles*) of the *Insectivora*, the phalangers of the *Quadrumana*, the wombat of the *Rodentia*, and the kangaroos, in a remoter degree, that of the *Ruminantia*. The first collection of mammalian fossils from the ossiferous caves of Australia[1] brought to light the former existence on that continent of larger species of the same peculiar marsupial genera:—some, as the *Thylacine*, and the dasyurine sub-genus represented by the *D. ursinus*, are now extinct on the Australian continent, but one species of each still exists on the adjacent island of Tasmania; the rest were extinct wombats, phalangers, potoroos, and kangaroos,—some of the latter (*Macropus Atlas*, *M. Titan*) being of great stature. A single tooth, in the same collection of fossils, gave the first indication of the former existence of a type of the marsupial group, which represented the Pachyderms of the larger continents, and which seems now to have disappeared from the face of the Australian earth. Of the great quadruped so indicated under the name *Diprotodon* in 1838, successive subsequent acquisitions have established the true marsupial character and the near affinities of the genus to the kangaroo (*Macropus*), but with an osculant relationship with the herbivorous wombat. The entire skull of the *Diprotodon Australis* (fig. 113) has lately been acquired by the British Museum, showing *in situ* the tooth (*i*) on which the genus was founded. This skull measures 3 feet in length; that of a man

[1] Mitchell's (Sir Thos.) *Three Expeditions into the Interior of Australia*, 8vo, 1838, vol. ii., p. 359.

is inserted in the cut to exemplify the huge dimensions of the primeval kangaroo. Like the contemporary gigantic sloth in South America, the Diprotodon of Australia, while retaining the dental formula of its living homologue, shows great and remarkable modifications of its limbs. The hind pair were much shortened and strengthened, compared with those of the kangaroo; the fore pair were lengthened as well as strengthened; yet, as in the case of

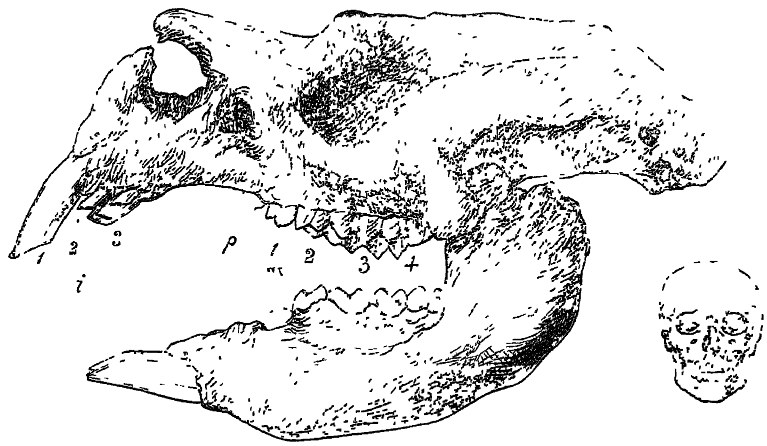

Fig. 113.

Skull, gigantic Pachydermoid Kangaroo (*Diprotodon Australis*) Pleistocene, Australia.

the Megatherium, the ulna and radius were maintained free, and so articulated as to give the fore paw the rotatory actions. These, in *Diprotodon*, would be needed, as in the herbivorous kangaroo, by the economy of the marsupial pouch. The dental formula of *Diprotodon* was $i\frac{3-3}{1-1}$, $c\frac{0}{0}$, $p\frac{1-1}{1-1}$, $m\frac{4-4}{4-4}=28$,[1] and, as in *Macropus major*, the first of the grinding series (p) was soon shed; but the other four two-ridged teeth were longer retained, and the front upper incisor (i, 1) was very large and scalpriform, as in the wombat. The zygomatic arch sent down a process for augmenting the origin of the masseter muscle, as in the kangaroo. The foregoing skull, with parts of the skeleton, of the *Diprotodon Australis*, were discovered in a lacustrine deposit, probably pleistocene, intersected by creeks, in the plains of Darling Downs, Australia.

The same formation has yielded evidence of a somewhat smaller extinct herbivorous genus (*Nototherium*), combining, with essential affinities to *Macropus*, some of the characters of the Koala (*Phascolarctus*).[2] The writer has recently communicated descriptions and figures of the entire skull of the *Nototherium Mitchelli* to the Geological Society of London.[3] The genus *Phascolomys* was at the same period represented by a wombat (*P. gigas*) of the magnitude of a tapir, one of the grinding teeth of which is represented, of the natural size, in fig. 114.

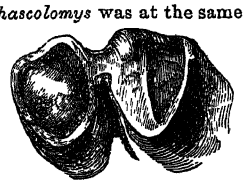

Fig. 114.
Grinding Surface of Molar of *Phascolomys gigas* (nat. size), Pleistocene, Australia.

The pleistocene marsupial *Carnivora* presented the usual relations of size and power to the *Herbivora*, whose undue increase they had to check. Fig. 115 represents an almost entire skull, with part of the lower jaw of an animal rivalling the lion in size, the marsupiality of which is demonstrated by the position of the lacrymal foramen (l) in front of the orbit; by the palatal vacuity (o), by the loose tympanic bone, the development of the tympanic bulla in the alisphenoid, by the very small relative size of the brain, and other characters detailed in a Memoir lately communicated by the writer to the Royal Society of London. The carnassial tooth (p) is 2 inches 3 lines in longitudinal extent, or nearly double the size of that in the lion. The upper tubercular tooth (m, 1) resembles in its smallness and position that in the placental Felines. But in the lower jaw the carnassial (p) is succeeded by two very small tubercular teeth (m, 1 and 2), as in *Plagiaulax* (fig. 88); and there is a socket close to the symphysis of the lower jaw of *Thylacoleo* which indicates that the canine may have terminated the dental series there, and have afforded an additional feature of resemblance to the *Plagiaulax*.

The foregoing are some of the more interesting illustrations of the law, that "with extinct as with existing Mammalia, particular forms were assigned to particular provinces, and that the same forms were restricted to the same provinces at a former geological period as they are at the present day."[4] That period, however, was the more recent tertiary one.

In carrying back the retrospective comparison of existing and extinct Mammals to those of the eocene and oolitic strata, in relation to their local distribution, we obtain indications of extensive changes in the relative position of sea and land during those epochs, in the degree of incongruity between the generic forms of the Mammalia which then existed in Europe and any that actually exist on the great natural continent of which Europe now forms part. It would seem, indeed, that the further we penetrate into time for the recovery of extinct Mammalia, the further we must go into space to find their existing analogues. To match the eocene Palæotheres and Lophiodons, we must bring Tapirs from Sumatra or South America, and we must travel to the antipodes for Myrmecobians, the nearest living analogue to the Amphitheres of our oolitic strata.

On the problem of the extinction of species little can be said; and of the more mysterious subject of their coming into being, nothing profitable or to the purpose at present. As a cause of extinction in times anterior to man, it is most reasonable to assign the chief weight to those gradual

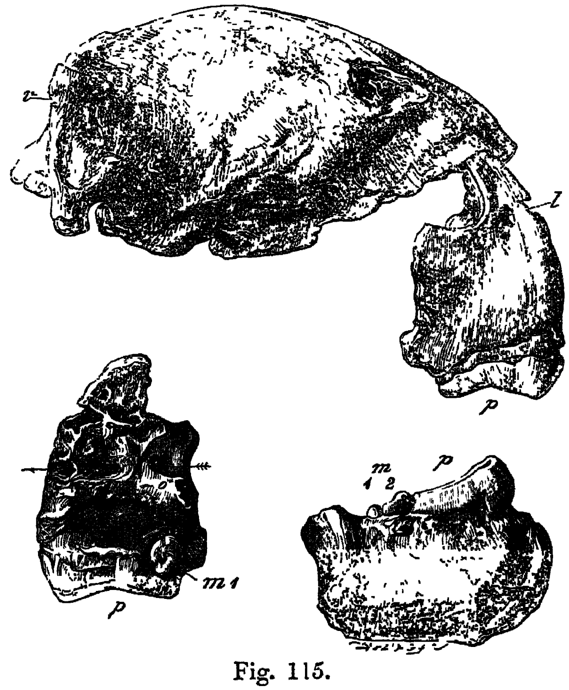

Fig. 115.

Skull of a large extinct Marsupial Carnivore (*Thylacoleo carnifex*), Pleistocene, Australia.

changes in the conditions affecting a due supply of sustenance to animals in a state of nature which must have accompanied the slow alternations of land and sea brought about in the æons of geological time. Yet this reasoning

---

1 See that of *Macropus*, explained in art. ODONTOLOGY, p. 449.
2 "Report on the Extinct Mammals of Australia," *Trans. of Brit. Assoc.* 1844.

is applicable only to land-animals; for it is scarcely conceivable that such operations can have affected sea-fishes. There are characters in land-animals rendering them more obnoxious to extirpating influences, which may explain why so many of the larger species of particular groups have become extinct, whilst smaller species of equal antiquity have survived. In proportion to its bulk is the difficulty of the contest which, as a living organism, the individual of such species has to maintain against the surrounding agencies that are ever tending to dissolve the vital bond, and subjugate the living matter to the ordinary chemical and physical forces. Any changes, therefore, in such external agencies as a species may have been originally adapted to exist in, will militate against that existence in a degree proportionate to the bulk of the species. If a dry season be gradually prolonged, the large Mammal will suffer from the drought sooner than the small one; if such alteration of climate affect the quantity of vegetable food, the bulky Herbivore will first feel the effects of stinted nourishment; if new enemies be introduced, the large and conspicuous animal will fall a prey, while the smaller kinds conceal themselves and escape. Small quadrupeds are more prolific than large ones. Those of the bulk of the Mastodons, Megatheria, Glyptodons, and Diprotodons are uniparous. The actual presence, therefore, of small species of animals in countries where larger species of the same natural families formerly existed, is not the consequence of degeneration,—of any gradual diminution of the size of such species,—but is the result of circumstances which may be illustrated by the fable of the "oak and the reed;" the smaller and feebler animals have bent and accommodated themselves to changes to which the larger species have succumbed.

That species should become extinct, appears, from the abundant evidence of the fact of extinction, to be a law of their existence. Whether, however, it be inherent in their own nature, or be relative and dependent on inevitable changes in the conditions and theatre of their existence, is the main subject for consideration. But admitting extinction as a natural law, which has operated from the beginning of life, it might be expected that some evidence of it should occur in our own time, or within the historical period. Reference has been made to several instances of the extirpation of species, certainly, probably, or possibly, due to the direct agency of man. But this cause avails not in the question of the extinction of species at periods prior to any evidence of human existence: it does not help us in the explanation of the majority of extinctions, as of the races of aquatic Invertebrata and Vertebrata which have successively passed away. Within the last century, Academicians of Petersburg and good Naturalists described and gave figures of the bony and the perishable parts, including the alimentary canal, of a large and peculiar fucivorous Sirenian,—an amphibious animal like the Manatee, which Cuvier[1] classified with his herbivorous *Cetacea*, and called *Stelleria*, after its discoverer. It inhabited the Siberian shores and the mouths of the great rivers there disemboguing. It is now believed to be extinct, and this extinction has not been due to any special quest and persecution by man. We may discern in this fact the operation of changes in physical geography, which have at length so affected the conditions of existence of the *Stelleria* as to have caused its extinction. Such changes had operated, at an earlier period, to the extinction of the Siberian elephant and rhinoceros: a future generation of zoologists may have to record the final disappearance of the Arctic buffalo (*Ovibos moschatus*). Remains of *Ovibos* and *Stelleria* show that they were contemporaries of *Elephas primigenius* and *Rhinoceros tichorrhinus*. The great auk (*Alca impennis*, L.) existed in the last century: no specimen has been obtained within the present. Scandinavian naturalists believe it to be extinct. It has not been specially hunted down, like the dodo and dinornis; but by degrees has become more and more scarce. Physical changes, slowly operating, seem to have affected its sources of food and other circumstances favourable to its well-being. The numbers of its bones on the shores of Iceland, Greenland, and Norway, attest the abundance of the bird in former times. A consideration of such instances of modern extinctions may best throw light, and suggest the truest notions, of the causes of ancient extinctions.

As to the successions, or coming to be, of new species, one might speculate on the possibility of a variety of auk being occasionally hatched with a somewhat longer winglet and a dwarfed stature,—of such a variety better adapting itself to the changed climatal conditions than the old type, —of such an origin, for example, of *Alca torda*;—but to what purpose? Past experience of the chance aims of human fancy, unchecked and unguided by observed facts, shows how widely they have ever glanced away from the gold centre of truth. (R. O.)

PALÆSTRA (παλαίστρα, from πάλη, *wrestling*), signifies properly a wrestling-school, but seems to have been used among the Greeks as sometimes synonymous with gymnasium, generally as forming a part of the gymnasium (Herod. vi. 126, 128), and occasionally as distinct from it. The Romans used the terms as synonymous. (Vitruv. v. 11.) (See GYMNASIUM.)

PALAFOX-Y-MELZI, DON JOSÉ, a valiant Spanish patriot, was born of an old family in 1780, and was brought up at court. He was still a young man, living in retirement at his hereditary seat of Torre del Alfranca, when Napoleon's troops, in 1808, were threatening the neighbouring city of Saragossa. The citizens intrusted him with their defence, by electing him to be captain-general of the kingdom of Aragon. He assumed this office under circumstances very formidable and perplexing. His own experience in military affairs was very small; the town was almost destitute of soldiers, defences, and resources; and the adjacent provinces of Navarre and Catalonia were invested by French troops disciplined in many a campaign, and flushed with many a victory. Yet the great natural tact and commanding spirit of the young leader surmounted all these embarrassments, and promptly organized a regular system of resistance. Soldiers from all the surrounding districts were summoned into town, every street was barricaded, every house was made a point of defence, and the inhabitants were formed into one united band, unanimous in their determination either to protect the city or perish beneath its ruins. Scarcely had Palafox completed these preparations, when a French force under Lefebvre-Desnouettes approached and began the siege. Then ensued a series of the most determined attacks and repulses. Often did the besiegers, with cool veteran courage, force their way into the city: as often did the besieged, with wild and desperate recoil, drive them back to their intrenchments. The besiegers seconded their onsets with a demand for capitulation; the besieged rallied their courage with the cry of "War to the very knife." At length, after a bloody siege of sixty-one days, the bravery of the citizens proved invincible; and on the 14th August the French retired, baffled, towards Pamplona. Palafox and his army had not long enjoyed their hard-won renown, when fate interposed with relentless hand to snatch from them the fruits of their success. The French returned in greater force under

---

Marshals Moncey and Mortier, and applied their resistless resources to the siege of the obstinate city. In vain did men, women, and children, under a terrific bombardment, and amid tumbling houses, oppose their bodies to the assaulting foe. A wasting epidemic broke out, and reduced the defenders to a mere handful. The leader himself, falling ill, was obliged to resign the command, and his successor, St Marc, capitulated on the 21st February 1809. The events in the after part of Palafox's career are not very important. After suffering imprisonment in the dungeon of Vincennes, on account of his resistance to the French, he was liberated on the restoration of Ferdinand VII. in 1813. Although confirmed in the following year in the office of captain-general of Aragon, he soon ceased to take any part in politics. His death took place in 1847.

PALAIS, Le, a town of France, department of Morbihan, stands on the N. side of the island of Belle Isle. It is strongly fortified, and contains a citadel, which serves as a state prison. The harbour is good and safe; and there is a school of navigation. Some trade is carried on in fish. Pop. 4972.

PALAMAS, Gregorius, an eminent Greek ecclesiastic, was born about the beginning of the fourteenth century, and was brought up at the court of Constantinople. After imbibing for ten years the peculiar doctrines of the monks of Mount Athos, he shut himself up in a solitary cell near Berrhœa to practise these doctrines, and for the next ten years starved his body and mystified his brain by sitting in a dark corner, with his chin on his breast, and his eye fixed on his navel, in expectation of seeing a celestial light settle on that part of his frame. When Baarlam denounced these exercises, and ridiculed their observers with the nickname of *Omphalopsychi* ("navel-souls"), the zealous fanatic came forward as the champion of his sect. The controversy was referred to the ecclesiastical court of Constantinople, and Palamas retired from the post he had taken. At the councils which were severally held in 1341 and 1351, he pled the cause of his party, and so identified himself with the tenets he advocated that his fellow-sectarians were thenceforth called *Palamites*. The battle was now gained, and he retired to the see of Thessalonica. The time of his death is unknown. The published works of Palamas are *Prosopopœia*, or two judicial pleas of the body and soul against each other, published, with a Latin version by Combéfis, in his *Auctarium Novissimum*, folio, Paris, 1672; and a refutation of the statements of John Veccus, printed in the *Opuscula Aurea* of Petrus Arcudius, 4to, Rome, 1630.

PALAMOW, a district of British India, presidency of Bengal, lying between N. Lat. 23. 12. and 24. 22., and E. Long. 83. 18. and 84. 31.; and bounded on the N. by the districts of Behar and Ramgurh, E. by that of Ramgurh, S. by that of Chota Nagpore, S.W. by that of Sirgoojah, and W. by that of Mirzapoor. Length from S.E. to N.W., 88 miles; breadth, 70 miles; area, 3468 square miles. The country has never been thoroughly explored. The Koel is the only river in Palamow that is perennial in its flow. The hills and valleys of the district are densely covered with forests and jungles, which are the haunts of many wild animals. Most valuable sources of mineral wealth exist. There are numerous scattered villages throughout the country; and two places that may be called towns,—Palamow, near the centre; and Oontaree, on the northern boundary. Pop. (1855) of the districts of Palamow and Chota Nagpore, 482,900.

PALATINATE (Germ. *Pfalz*), an ancient division of Germany, consisting of two parts, the Upper and the Lower Palatinate. The former, having an area of 2756 square miles, lay to the N.E. of Bavaria, of which kingdom it now forms the circles of Upper Palatinate and Upper Franconia. The Lower Palatinate, which had an area of 1590 squares miles, lay on both sides of the Rhine, between Worms and Carlsruhe. It is now divided among Rhenish Prussia, Baden, and Bavaria. The portion included in the last of these countries forms the modern circle of Palatinate. (See Bavaria.)

PALAWAN, or Paragua, an island of the Eastern Archipelago, separating the Chinese from the Sooloo Sea. [illegible] N. Lat. 8. 27. and 11. 32., E. Long. 117. 18. and 119. 48., and extends from the Philippine Islands on the N.W. to the vicinity of the northern extremity of Borneo. Its length is about 275 miles, and its average breadth 32 miles. The eastern part, for about 10 or 20 miles from the sea, is low and flat; but near the western coast a chain of hills runs through the island. It is well watered, and has a fertile soil, which for the greater part is not cultivated. The natural products resemble those of Borneo, including rice, honey, wax, bulrushes of a white colour that are much valued, and many other articles. Gold and pearls are obtained here. Among the animals are leopards, porcupines, several kinds of squirrels, and many birds of rare and beautiful plumage. It is inhabited by people in a very savage state; [illegible] portion is possessed by the Sultan of Sooloo, and the Spaniards have long exercised dominion over the northern part, which belongs to the province of Calamianes. The hilly regions are held by the original natives, a people resembling the Papuans. The principal town is Babuyan, which is fortified, and has about 2000 inhabitants.

PALAZZUOLO, or Palazzolo, a town of Sicily, province of Syracuse, stands on a bleak hill, 19 miles W. of Syracuse. It occupies the site of the ancient Acræ, a colony founded by Syracuse, B.C. 663. Many interesting antiquities have been found here, especially remains of temples and of two theatres, statues, and other relics. Pop. 8600.

PALEMBANG, a Dutch province in the island of Sumatra, comprehending the former kingdom of that name, along with the district of Jambi, extends along the east coast of the island, and is bounded on the N.W. by the Battah country, N.E. and E. by the Banka Strait, S. by the province of Lampong, and W. by that of Bencoolen. Near the sea is a low, flat, and marshy tract of ground; but towards the interior the country is hilly, and contains several volcanoes, one of which, near the frontier of Bencoolen, did much injury by an eruption in 1833. The country is watered by several considerable rivers, such as the Mœsi, Komering, Lamatang, and others; and the soil is very fertile, producing pepper, bamboos, lacquer-wood, &c. European vegetables grow well; and live stock thrive better here than in Java. In the year 1811, the Dutch had merely a commercial factory at Palembang, when the sultan began hostilities against them; and in order to their entire destruction, under pretence of conveying them safely to Batavia, sunk during the night the ships in which they had embarked by means of holes previously made. But the hopes which had been entertained of gaining by this murderous deed the favour of the British, then in possession of Java, were disappointed, for an expedition sent by them dethroned the sultan, and placed his younger brother on the throne. The Dutch having, in 1816, regained their East Indian possessions, the sultan complained of his deposition; and having satisfied the government of Batavia of his innocence of the crime imputed to him, was reinstated in 1818. But soon he began fresh assaults on the Dutch; and suddenly one morning their factory was cannonaded by the guns of his fort. They made an unsuccessful expedition against Palembang; and the country remained in rebellion till 1821, when it was conquered by them. The sultan still retains his title, but the supreme power is exercised by a Dutch regent, who resides at Palembang, the capital. The internal administration, however, is in the hands of the native chiefs. This town stands on both sides of the Mœsi, about 50 miles above its mouth. It is built

chiefly of wood and bamboos, but the sultan's palace and the principal mosque are stone edifices. The river is here deep and navigable; and an active trade is carried on. Pop. about 25,000. The province of Palembang is but thinly peopled.

PALENCIA, a province in the interior of Spain, one of the eight into which Old Castile is divided. It has an area of 258 square leagues, and the following boundaries:—N., Santander; E., Burgos; S., Valladolid; W., Leon and Toro. The partidos into which it is divided are Astudillo, Baltanas, Carrion, Cervera de Rio Pisuerga, Frechillas, Palencia, and Saldaña. The surface is in general level, and almost devoid of trees; the northern part of the province, comprising the whole of the partido of Cervera, is mountainous. The climate is generally cold, especially in the north, but healthy, and would be much more so but for the almost entire want of trees. The numerous streams which traverse the province contribute to its remarkable fertility: the principal are the Pisuerga and the Carrion, which cross the province from N. to S., uniting near Dueñas, and passing into the province of Valladolid; the Camera, the Cieza, the Arlanza, the Abanades, &c. The canal of Castile crosses the province also from N. to S., with a branch through Tierra de Campos, and by facilitating the exportation of its grain, has done good service to the agriculture of the province. The whole partido of Cervera abounds in minerals, but the coal is the only mineral that is worked. There are mines at San Felices de Castilleria, 2 leagues N. of Cervera, and at Orbó, 3 leagues from Cervera, both furnishing coal of good quality, and plentiful; and several others in Villaverde de la Peña. In all the partidos, with the exception of Cervera, wheat and other cereals, legumes, hemp, and flax are produced in abundance; in Cervera the land is occupied with pastures and with wood. In the numerous gardens by the water-courses are grown all kinds of fruit, with the exception of the olive; but linseed oil is plentifully produced. Game is abundant in Cervera; and the Pisuerga and Carrion are good fishing streams. The principal industry is the manufacture of flour, and the principal commerce its exportation to Cataluña and the Havannah. The woollen manufactures of blankets, serges, and baize are tolerably extensive. There is a fair provision of elementary instruction in the province, which contains about 600 schools of this class; for secondary instruction there is only one, in the capital. Pop. 148,491.

PALENCIA, capital of the above province, is situated in a plain on the left bank of the Carrion, 2 leagues above its confluence with the Pisuerga. The environs of the town on the W. are delightful, presenting to the view gardens, trees on the banks of the Carrion, and numerous fountains. The climate is somewhat cold, but salubrious: most equal in autumn. The city is protected on the W. by the river, and on the other sides by a wall, dating from the re-conquest, of 36 feet in general height, and 9 in thickness, solidly built with stone, with some additional constructions in the recent war, and affording entrance by seven gates. The city is divided into two parts, the ciudad and the puebla: in the latter, occupied chiefly by the working classes, the streets are straight and commodious, the houses of a single storey; in the former the streets are narrow, the houses of two storeys, with courts and sometimes gardens. The principal buildings are,—the cathedral, of Gothic style, begun in the fourteenth century, and finished in the seventeenth; the episcopal palace, an unfinished building, with fine gardens; the palace of Don Sancho, King of Navarre, in the centre of the city; and the hospital, an immense building of stone. There are, besides, four churches and ten convents, not remarkable for their architecture. The school of secondary instruction has 11 professors; the *seminario conciliar*, in the ex-convent of the Jesuits, has 8. There are, besides, nine schools of primary instruction. The chief industry of the town consists in the fabrication of woollens, for which it is celebrated. Its mantas, serge, and baize supply Spain, Portugal, and America, and their manufacture occupies a third part of the population, besides that employed in the bleaching and dyeing works connected with it. Next to this in importance is the manufacture of flour. There are also manufactures of chocolate, brandy, &c., and of common earthenware. Palencia, under the name of *Pallantia*, was a wealthy and considerable city in the time of the Romans, and makes a considerable figure in Spanish history. Pop. 10,490.

PALERMO (anciently *Panormus*, Fr. *Palerme*), the second city of the kingdom of Naples, and the capital and chief seaport of Sicily, stands on the south-western shore of a large bay on the north side of the island, in a rich plain surrounded on three sides by hills, which, from its form and beauty, has received the name of *Conca d'Oro*, or "Golden Shell;" N. Lat. 38. 8., E. Long. 13. 22. The many cupolas, turrets, and spires that rise to the view of one looking at it from the sea, gives to Palermo a noble and striking aspect. In form it is nearly rectangular, its shortest side extending along the shore; and it is surrounded by old walls, which are entered by numerous gates. The other defences of the place consist of a citadel, bastions, and batteries, which render the town strong against an attack from the sea, though it is not well protected on the land side. The buildings of Palermo are distinguished by considerable regularity, and those that line the principal streets are very handsome. The principal streets, two in number, cross at right angles near the centre of the town, thus dividing it into four nearly equal parts. They are well paved with lava, and form at their intersection a public place of an octagonal form, four sides of which are occupied by these streets, and each of the others by a handsome three-storeyed building of Grecian architecture. Many statues stand and fountains play in this place, from which a fine view may be obtained of the four avenues of houses terminating in the gates of the town. The inferior streets are equally well paved with the principal ones, but they are frequently in a very dirty and disagreeable state. Palermo contains several other public places, some of them of considerable size. But the most frequented places of resort for amusement are the Marina and the Flora; the former of which is a public walk, about 80 yards broad, stretching for more than a mile along the sea-shore; and the latter a beautifully laid out and ornamented garden near the eastern corner of the town. Many of the private houses are remarkable for the splendour of their architecture, but they very frequently err in a want of simplicity, and in a profusion of ornament. They are generally lofty, and, like those of Naples, have flat, terraced roofs and projecting balconies. The most of them are divided into flats, each forming a distinct dwelling. Strange and lively is the scene that the streets of Palermo present to a stranger. Close to the most splendid palaces wretched booths often project into the street; workmen of all kinds pursue their trades on the pavement in front of their shops; while the sides of the streets are also occupied by crowds of beggars, and idlers of higher rank sit in front of the coffee-houses; so that all the passengers on foot, as well as in carriages or on horseback, have to proceed indiscriminately along the centre of the streets. The public buildings are numerous, and many of them sumptuous,—more so, indeed, generally, than is consistent with good taste. The cathedral, which was built in 1180, is a fine edifice in the Gothic style; but in recent times a dome has been added, and the interior has been re-modelled after the Grecian style. It contains many tombs in red porphyry, among which are those of King Roger the Norman, and the Emperor Frederick II. The church of St Joseph is remarkable for its crypt and gray marble columns. There are, besides those

already mentioned, many other churches, all rich in paintings, sculptures, and mosaics, and all very similar in their general appearance and style. Palermo has also seven abbeys and about seventy convents. The palace in which the viceroy resides occupies a beautiful situation in the midst of gardens at the S.W. end of the town. It is an ancient irregular building, in various styles of architecture, and contains a hall, many other fine buildings, a picture gallery, a beautiful chapel built by Roger the Norman in 1129, and an observatory, from which, on the 1st of January 1801, the planet Ceres, the first known of the asteroids, was discovered by Piazzi. In front of the palace is a public square, containing, among other statues, one in bronze of Philip IV. of Spain. The university of Palermo was founded in 1447, or, according to other accounts, as early as 1394; but it is now in a declining state. It has a library of 40,000 volumes, and a valuable collection of antiquities. The interests of education are provided for at Palermo by several other institutions for different branches of instruction. The account of the public buildings of Palermo would not be complete without taking notice of the archbishop's palace, court-house, custom-house, mint, *monte di pietà*, prison, barracks, arsenal, and several theatres. It is the seat of an archbishop, and of the lieutenant-general of Sicily. The public charities consist of several hospitals, a poor-house, a foundling institution, lunatic asylum, and other establishments. In the neighbourhood of the town are many fine country houses of the Sicilian nobility, and, among the rest, a royal residence in the Chinese style. There are also two fine specimens of Moorish architecture,—the grotto of St Rosalia on the Monte Pellegrino, which is a great object of veneration to the Sicilians; and a Capuchin convent, with curious catacombs. As a manufacturing town, Palermo is not very important. The chief branch carried on is the making of silken stuffs, which was begun here in the eleventh century; cotton, oil-cloth, gold and silver articles, hardware, &c., are also produced; and the tunny fisheries on the coast give employment to 3000 or 4000 of the inhabitants, and yield ample returns. The situation of the town, and its excellent harbour and anchorage, afford great facilities for foreign commerce; but the intercourse with the interior of Sicily is greatly hindered by the want of sufficient means of conveyance in the island. The harbour, which lies outside of the walls, is formed by a mole, constructed at a cost of L.1,000,000, extending southwards for a quarter of a mile into the sea. The principal articles exported from Palermo are shumac, oranges and other fruits, oil, wines, spirits, manna, brimstone, liquorice, raisins, and grain; and there are imported silken, cotton, and woollen stuffs; hides, timber, tobacco, sugar, hardware, &c. The total value of the exports in 1852 was L.698,744, of which L.294,989 were to the United Kingdom and its colonies, and L.448,755 to other countries. The whole imports in the same year amounted in value to L.606,083, of which L.253,089 were from the British empire, and L.352,994 from other countries. Communication is kept up between Palermo and Naples, both directly by sea and through Messina and Reggio; but the means of conveyance are barely sufficient for the necessities of commerce. Since 1850 the port has been frequently visited by British steamers engaged in commerce. In 1854 the number of these that entered was 27, and their average tonnage 543. Some traces of an ancient amphitheatre have been found near the palace, and many fragments of marble and other remains have been obtained; but these are all that have come down to us of the ancient Panormus. Although this name, by which it was generally known in ancient times (being derived from the excellence of the harbour), was of Greek origin, there is no doubt that it was not by that nation, but by the Phœnicians, that the town was founded. It was at one time among their principal places in Sicily; but at the earliest historical period at which Panormus is brought into notice, it was no longer subject to its mother country. This was in 480 B.C., when the Carthaginians under Hamilcar made it their head-quarters against Himera. How it came into their hands we have no means of knowing; but it continued for a long time to be their principal naval station in Sicily, and the capital of their possessions in that island. It was taken by Pyrrhus in 276 B.C., but was soon after recovered by Carthage. During the first Punic war, in 254 B.C., Panormus was taken by that people, and four years after, a decisive victory was gained by them under the walls. Before the close of this war the Monte Pellegrino, then called *Ercta*, was occupied by Hamilcar Barca; and such was the strength of the position, that for three years he held out against the utmost efforts of the Romans. After the conquest of Sicily by that people, Panormus enjoyed the privileges of a free town, and became the chief place of commerce and navigation in the island. It afterwards lost its freedom, and received a Roman colony; but throughout the time of the empire it continued in a flourishing condition, though it never reached that importance which it now possesses. When Sicily was conquered by the Goths, Palermo, along with the rest of the island, fell into their hands; but it was recovered by Belisarius, and the Byzantine Empire retained possession of it till 855 A.D., when it was taken by the Saracens, and made the capital of their Sicilian possessions. Since that period Palermo has been, with few intervals, the capital of Sicily, and has followed the fortunes of that island. It has suffered at various times from earthquakes; and during the Sicilian insurrection in 1848 it was bombarded by the royal troops, and partially destroyed. Pop. (1856) 200,000.

Palermo, the province of which the above town is the capital, is bounded on the N. by the Mediterranean, E. by the provinces of Messina and Catania, S. by that of Trapani, and W. by those of Girgenti and Caltanisetta; length from N.W. to S E., 66 miles; breadth, 48 miles; area, 1985 square miles. The coast is irregular; and the surface consists of barren hills and rich valleys, having a general slope towards the north. Numerous small streams flow through the province into the Mediterranean. The country produces corn, oil, fruits, almonds, manna, shumac, liquorice, silk, &c. It is the largest and the best peopled of the Sicilian provinces. Pop. (1856) 541,326.

PALES, a Roman divinity of flocks and shepherds, represented by some writers as a female, and by others as a male, but embodying the same idea as Pan among the Greeks. A festival, termed *Palilia*, and sometimes *Parilia*, as if *a pariendo*, was celebrated annually at Rome, in honour of this tutelary deity, on the 21st of April, the anniversary, according to early tradition, of the foundation of Rome by Romulus. (Varro, *De Ling. Lat.*, vi. 15; Cicero, *De Div.* ii. 27.) From the *Fasti* of Ovid (iv. 731, &c.), we learn that the solemnities of this festival began by a public purification by fire and smoke. Towards the evening, when the shepherds had fed their flocks, the stables were adorned with laurel boughs, and the smoke of burnt sulphur, rosemary, fir-wood, and incense, was made to pass through the stalls to purify them. The flocks themselves were also purified by this smoke, and were made to pass through bonfires made of heaps of hay and straw. After the offerings were over, which consisted of cakes, millet, milk, &c., the shepherds engaged in prayer to Pales. and thus terminated the solemn part of the proceedings. This was followed up by the most festive joviality, the shepherds bounding over the *flamma Palilis*, or bonfire, with great spirit, to the sound of cymbals and flutes. They next ranged themselves on benches of turf, ate plentifully, and drank without stint, till the Palilian constellation (Hyades) had vanished in the evening twilight.

PALESTINE.

Palestine. THE land of God's chosen people, and the scene of the earthly labours and sufferings of our Lord, has commanded, and ever must command, a greater share of attention than any other. No ancient country has been so much visited by travellers in all ages and from all parts of Christendom, and of none have so many books been written. Greece, Rome, and the other seats of early civilization, each present to us features of interest; but those of Palestine are greater, and of a kind peculiarly its own. Its physical features and productions, the history and manners of its people, their language with its idioms and proverbs, are all more or less interwoven with the expressions of our religion, and have been familiar to us from our earliest years.

The Holy Scriptures were primarily committed to a people living at a particular time, surrounded by certain scenes, and familiar with certain objects, to which frequent allusions are made which are apt to be unintelligible or misunderstood by those who are ignorant of the time and circumstances. A knowledge of the country and people of Palestine farther gives a peculiar beauty and force to numerous passages in the sacred writings, and will hence ever commend itself to the careful study of the intelligent Christian. Changes may no doubt have taken place in the climate, productions, and general aspect of the country since the times of the Old and New Testaments, but still the great characteristics remain. These are witnesses to the events that have occurred in their presence. "They can be cross-examined with the great facts and narratives. If they cannot tell the whole truth, at any rate, so far as they have any voice at all, they tell nothing but the truth." (Stanley's *Sinai and Palestine.*)

From another point of view, it is important to notice how admirably adapted, above every other, was this country for the abode of that people to whose keeping were committed the principles of a religion destined to be universal. It was more varied in its characteristics than probably any other district on the face of the earth, containing within its range more or less of the natural features of almost every other. Had it been less varied or more eastern in its character, it is not unreasonable to suppose that the sacred writings would have contained less with which the European mind could sympathize. It was farther eminently fitted for preserving that religion in its purity. It presented no grand natural features which in other countries elicited from the human heart divine honours;[1] its coasts were singularly deficient in harbours to tempt to commerce and commercial alliances; huge natural barriers were interposed between it and the two great centres of civilization in the eastern world, Egypt and Babylon, the corrupters of all the nations of the earth; the wild grandeur of Sinai was, like the body of Moses, hid from the people lest they might worship it; and the lofty Lebanon, though visible in the distance, formed no part of their allotted territory. The inhabitants, too, partook of the exclusive nature of their country, and kept aloof from every other nation or people whom they looked upon as barbarians. They were not suffered to remain in Egypt nor in Babylon; and, to our mind, there is no stronger evidence that their mission is not yet fulfilled than is to be found in the fact that, though 1800 years have elapsed since they were driven out of their own country, and ceased to have any fixed abiding-place, they are yet as a people as distinct as when dwelling in their own land. They, too, were as varied in their character and circumstances as was the country in its physical aspects. They belonged to every rank and condition of life; and hence the Scriptures, though coming to men in a particular time and in particular circumstances, are yet preeminently adapted for men in all time and in all circumstances.

Palestine. Notwithstanding the great number of travellers that have visited Palestine, to no one more than to Dr Robinson are we indebted for what is now known of the geography of that country. With the publication of his *Biblical Researches* in 1841 a new era may be said to have commenced in biblical geography. Up to his time travellers in Palestine were guided almost entirely by the traditions of the monasteries—traditions originally established, for the most part, by persons ignorant of the topography of the country and of the language of the people, long after the events for which they were celebrated took place. All these Dr Robinson, in the outset, resolved to set at defiance; and accordingly he proceeded on the principle that "all ecclesiastical tradition respecting ancient places in and around Jerusalem, and throughout Palestine, is of no value except so far as it is supported by circumstances known to us from the Scriptures, or from other contemporary testimony." The traditions and the evidence from names and associations surviving among the native Arabs he held to be much more reliable; and unquestionably the common Arabic population, aside from the ordinary routes of travel, untainted with ecclesiastical traditions and superstitions, unbiassed by any motive to err or to deceive, are a better authority for the names of places in Palestine than are the monks of Nazareth or Bethlehem. His companion, Dr Eli Smith, was admirably qualified for carrying out this branch of investigation, having by long residence acquired a thorough knowledge of the Arabic people and a complete mastery of their language. Dr Robinson, too, had prepared himself for his researches by a course of study extending over a period of nearly twenty years. The two great principles by which they were guided in their investigations were, first, "to avoid, as far as possible, all contact with the convents and the authority of the monks; to examine everywhere for ourselves, with the Scriptures in our hands, and to apply for information solely to the Arab population;" and secondly, "to leave as much as possible the beaten track, and direct our journeys and researches to those portions of the country which had been least visited." After an interval of fourteen years, Dr Robinson again visited Palestine, and again his companion during the more important part of his journey was Dr Smith. The results of this second visit were published in his *Later Researches*, which appeared in 1856. In his two journeys, Dr Robinson has identified, or been the first Frank traveller to visit, about 150 ancient places; and though in some cases his positions have been contested, his works are universally acknowledged to be the most valuable and reliable that have yet appeared. We trust that he may still be spared to complete the work for which his long course of study and laborious investigations have so

---

[1] "Whilst the great seats of Greek and Roman religion at Delphi and Lebadea, by the lakes of Alba and of Aricia, strike even the indifferent traveller as deeply impressive, Shiloh and Bethel, on the other hand, so long the sanctuaries and oracles of God, almost escape the notice even of the zealous antiquarian, in the maze of undistinguished hills which encompass them. The first view of Olivet impresses us chiefly by its bare matter-of-fact appearance; the first approach to the hills of Judea reminds the English traveller not of the most but of the least striking portions of the mountains of his own country." (Stanley.)

eminently qualified him. To quote his own words in the preface to his later work, "The great object of all these travels and labours has been, as formerly announced, to collect materials for the preparation of a systematic work on the physical and historical geography of the Holy Land."

Of a different and more popular character is Mr Stanley's *Sinai and Palestine*, 1856,—a work which will perhaps be more appreciated by the general public. Mr Stanley visited Palestine, not so much with a view to discovery, or for minute investigation, as to connect and illustrate the historical events of the Old and New Testaments with the existing topography of the country. It is in thus grouping together the physical features and the historical incidents of the region, that the main feature of Mr Stanley's work consists. He clothes with the reality of place the events of sacred history, and gives to the records of the past the actual life of the present. His descriptions of physical scenery are graphic and impressive, and his collocation of historical events is frequently striking—always apt and beautiful. Professor Carl Ritter has, with his usual ability, systematized and digested the voluminous records of centuries in his volumes on Palestine in his *Erdkunde*. Our limits prohibit us from noticing more of the numerous writers on Palestine; and this is the less necessary, as ample lists of them are to be found in the works of Robinson, Kitto, Ritter, and others.

Name. The name Palestine, by which this country is now commonly known, occurs nowhere in the Hebrew Scriptures. The word from which it is derived, and which is sometimes translated *Palestina* in our English version, is *Philistia* (Heb. פלשת; Gr. παλαιστίνη), the name proper of the country of the Philistines, which comprised the southern portion of the coast plain of Canaan. This being the part of the country with which the Greeks were first and chiefly acquainted, they came to apply the name generally to the whole country; and Herodotus, who travelled there, terms the Hebrews, Syrians of Palestine. We find Josephus, too, occasionally using the word Palestine (παλαιστίνη) for the whole country, though he more frequently uses it in its more restricted sense, as applied to that part which was inhabited by the Philistines. The name by which this country is first designated in Scripture is the *Land of Canaan*, from its earliest inhabitants being descendants of Canaan, the fourth son of Ham. This, however, only comprised the territory lying between the Jordan and the Mediterranean, the region to the east of that river being called the *Land of Gilead*. Referring to the period before it actually came into the possession of the children of Israel, it is called the *Land of Promise*—*i.e.*, the land which God had promised to Abraham to bestow upon his seed. The *Land of Jehovah* and the *Holy Land* are terms used as indicating God to be the sovereign proprietor of the soil, though in the present day the latter term is probably used more in regard to its having been the scene of the life and sufferings of Christ. The *Land of Israel* frequently occurs, first in reference to the whole country, but afterwards only to the territory of the ten tribes, which formed the separate kingdom of Israel as distinct from that of Judah. *Judea* and the *Land of Judah*, though originally applied to the territory of the tribe of Judah alone, and afterwards to the kingdom of Judah, came, after the captivity, to be sometimes applied in a loose way to the whole country.

Extent. One is at first naturally struck with the small extent of territory occupied by the children of Israel. The limits varied much at different times; but even in its more extended acceptation Palestine was not more than one-half the extent of Scotland, or one-fourth that of England and Wales. Its length from north to south was only about 180 miles, and its average breadth 65; its extreme breadth being only about 100 miles. This includes a considerable portion of territory beyond the Jordan, not comprised in Palestine proper or the Land of Canaan. The land beyond Jordan was not, it would seem, originally designed to form part of the land of Israel, which was to have been bounded by the River Jordan and its inland lakes. This is the land which, at their request, was given to the tribes of Reuben and Gad and the half tribe of Manasseh; and it is somewhat remarkable that these never emerged from their original nomadic state of life.

Situation and boundaries. Palestine is situated about midway between the equator and the polar circle, between 30. 40. and 33. 32. N. Lat., and 33. 45. and 35. 48. E. Long. It is bounded on the W. by the Mediterranean, E. by the Great Desert (now called the *Hauran*), S. by the desert which separates it from Egypt, and N. by the Lebanon Mountains. The boundaries are minutely laid down by Moses, in Numbers xxxiv. 3–12; but our present knowledge of the country is not sufficient to enable us to identify with certainty the limits there specified. The line of coast from north to south trends westwards, which causes the country between the coast and the valley of the Jordan to be much wider in the south than in the north. But where the country was narrowest there were possessions on the east of the river, and where widest there were none; and hence the actual breadth of territory was in some measure equalized throughout.

Physical character. Palestine is extremely varied in its physical characteristics,—"a land of hills and valleys." It is described in Deuteronomy (viii. 7–9) as "a land of brooks of water, of fountains, and depths, that spring out of valleys and hills; a land of wheat, and barley, and vines, and fig-trees, and pomegranates; a land of oil-olive and honey; a land wherein thou shalt eat bread without scarceness; thou shalt not lack anything in it; a land whose stones are iron, and out of whose hills thou mayest dig brass." The surface is generally mountainous, or, more properly, it is one mountain mass rising from a level sea-coast on the W. and from a level desert on the E. In the N. the roots of Lebanon form the high lands of Galilee, and are succeeded southward by the great plain of Esdraelon, stretching from the shores of the Mediterranean to the valley of the Jordan. Farther S. are the hills of Central Palestine, rising gradually into the mountains of Judah and Benjamin. The valley of the Jordan extends from N. to S. through the entire territory, and separates Palestine proper from the mountainous districts of Bashan, Gilead, and Moab.

Coast plains. The level country of the coast, lying between the sea and the high land of the interior, varies very considerably in breadth, in some parts expanding into wide plains, in others contracted into narrow passes; while occasionally the mountain offshoots stretch out into the sea, and form promontories along the coast. **Philistia.** The most southern portion of this coast country was the great plain occupied by the ancient Philistines, and termed in the Old Testament the Plain or Low Country. It extended from Joppa to Gaza, having on the W. the sea, and on the E. the hill country of Ephraim and Judah. The Philistines were not an indigenous race, though settled in Palestine as early as the time of the patriarchs, but were, as the name implies, "strangers," the general opinion being, that they were immigrants from the island of Crete. They became a great commercial people, and were a frequent source of annoyance to the children of Israel long after they had established themselves in Canaan. The fertility of their land must have contributed greatly to their power—rich corn-fields stretching without interruption from the low sandy tract on the shore to the base of the hills of Judah. "Two parallel tracts," says Stanley, "divide the flat plain; the sandy tract (Ramleh), on which stand the maritime cities, and the cultivated tract, which presents for the most part an unbroken mass of corn, out of which rise here and there slight

Palestine. eminences in the midst of gardens and orchards, the seats of the more inland cities. Gath has entirely disappeared; but Ekron, Ashdod, Gaza, and Ascalon retain their names, and the three last have sites sufficiently commanding to justify their ancient fame." "The most striking and characteristic feature of Philistia is its immense plain of corn-fields, stretching from the edge of the sandy tract right up to the very wall of the hills of Judah, which look down its whole length from N. to S. These rich fields must have been the great source at once of the power and the value of Philistia, the cause of its frequent aggressions on Israel, and of the increasing efforts of Israel to master the territory." The towns here are remarkable for the beauty of their situations and the profusion of gardens that surround them. They rise above the plain on their respective hills,—Ascalon and Jaffa on the sea-coast, and Gaza, Ashdod, and Ekron, at some distance from it.

Sharon. "The corn-fields of Philistia, as we advance farther N., melt into a plain less level and less fertile, though still strongly marked off from the mountain wall of Ephraim as that of Philistia was from that of Judah and Dan." (Stanley.) This is "Sharon;" and, like Philistia, it is divided into the *ramleh* or sandy tract along the sea-shore, and the cultivated tract farther inland, here called *khassab* ("the reedy"), apparently from the high reeds which grow along the banks of some of the streams. It is interspersed with corn-fields, and thinly studded with trees, the remnants apparently of a great forest which existed here down to the second century. Sharon, however, is chiefly noted for its rich pasture lands, and is, says Mr Monro, "clothed with fresh verdure as far as the eye can reach." The "rose of Sharon" he thinks to be the *Cistus roseus* of Linnæus, which is very abundant here. No historical name or event is attached to this district in the Old Testament; but then, as now, it was noted for the richness of its pastures. Under the Roman empire, however, it became of great note, and contained Cæsarea the Roman capital of Palestine. No human being now lives within many miles of this once rich and busy city, and the waves of the Mediterranean dash over its prostrate columns and huge masses of masonry. Beyond Cæsarea the plain becomes more contracted and irregular in its character, until the long ridge of Mount Carmel closes up its northern frontier.

Acre. Immediately N. of Mount Carmel, and between it and the ridge which forms the promontory of Râs Nakhora, is the plain of Acre, about 15 miles in length from N. to S., and about 5 in general breadth from the sea-shore to the hills which bound it on the E. It forms, so to speak, the embouchure of the great plain of Esdraelon, and, like the other plains, presents a sandy tract along the coast and a fertile tract inland. The soil of this last, though naturally rich, is now almost entirely uncultivated, but in the season presents a most exuberant natural vegetation. The town of Acre, or Accho, though of great antiquity, being one of the places from which the Israelites were unable to expel the ancient Canaanites, only became of importance in modern times. It is noted for the number of sieges it has sustained, and was called by Napoleon the "key of Palestine."

Phœnicia. The plain of Phœnicia lay N. of that of Acre, or more properly included it, extending S. to Mount Carmel. It is separated both geographically and historically from Palestine, though forming a natural continuation of the coast plain. Here were the great towns of Tyre and Sidon, at one time the great centres of commerce in the ancient world.

Carmel. Carmel is a mountain ridge 6 or 8 miles long, stretching N. by W. from the plain of Esdraelon into the sea, where it forms a high promontory, which incloses on the S. the Bay of Acre. It is about 1500 feet in height, and consists rather of several connected hills than of one ridge. No mountain in or around Palestine is said to retain its ancient beauty so much as Carmel;—its "excellency" is still to be seen. It is covered with rich verdure, and plentifully watered by numerous crystal streams. On its summits are pines and oaks, and farther down olives and laurel trees; while everywhere are to be seen fruits and flowers growing wild in great profusion. During the middle ages, the grottos of Carmel were the abodes of numerous monks, who thence took the name of *Carmelites*.

Lebanon. The Lebanon Mountains consist of two ranges, which come down parallel to each other from the N., and extend their southern branches into Palestine. The outer or western ridge, fronting the sea, into which it projects several promontories, was called *Libanus* by ancient writers; while to the inner or eastern range, fronting the plains of Damascus, they gave the name of *Anti-Libanus*. In the Bible the name Lebanon is applied to both ridges. On the loftiest summits, rising to the height of about 9300 feet, and in the fissures facing the north, snow may be seen all the year round. Inclosed between the two ridges of Lebanon is an extensive valley, called in Scripture "the valley of Lebanon," and by the ancients *Cœlesyria* ("the inclosed or hollow Syria"). Though it can scarcely be said to form any part of Palestine proper, yet its geographical and historical connection with that country renders some notice of it necessary. It is about 90 miles in length from N. to S., and about 11 in breadth throughout, except at the two ends, being somewhat wider at the northern, and narrower at the southern extremity. This plain is one of the most beautiful and fertile districts of Syria. It is abundantly watered by numerous mountain springs; but owing to the concentration of the sun's rays, the heat in summer is excessive. Only a small portion of it is cultivated, being chiefly used for pasture.

Galilee. Immediately S. of Lebanon is the high table-land of Galilee, extending to the plain of Esdraelon on the S., and sloping on the E. to the Jordan and its upper lakes, and on the W. to the plain of Acre. This table-land, which is estimated to have a general elevation above the level of the sea of from 900 to 1000 feet, is not without its eminences. The chief of these is Jebel Safet, 2770 feet above the level of the Mediterranean. The summit of this steep and lofty mountain is crowned by a castle; and a little below the summit is a city supposed by some to be that which our Saviour had in view in his Sermon on the Mount, as "a city set on a hill." The mountains of Galilee are as distinct in form as they are separate in fact from those of Samaria and Judea. "Those hills are the western roots which Hermon thrusts out towards the sea, as it thrusts out the mountains of Bashan towards the desert; and as such they partake of the jagged outline of the varied vegetation, and of the high upland hollows which characterize in a greater or less degree the whole mass of the Lebanon range, in contrast to the monotonous aspect of the more southern scenery." "It is one peculiarity of the Galilean hills, as distinct from those of Ephraim and Judah, that they contain or sustain green basins of table-land just below their topmost ridges." (Stanley.) In such a position stands Nazareth, inclosed by an amphitheatre of rounded hills.

Esdraelon. The high lands of Galilee are separated from the rest of Palestine on the S. by the plain of Esdraelon, extending from the shores of the Mediterranean Sea on the W. to the valley of the Jordan on the E. Its central and widest portion reaches straight across, without interruption, from the hills of Samaria to those of Galilee, and may be said to be in the form of a triangle, measuring about 14 miles on the N. side, 18 on the E., and 20 on the S.W. On the W. it is narrowed into a pass, through which flows its only stream, the Kishon; and beyond this the plain opens out again round the Bay of Acre. In the E. the surface is somewhat undulated by offshoots from the mountains; and here three great valleys go off to the

Palestine. valley of the Jordan. These valleys are separated from each other by the ridges of Gilboa and Little Hermon, the central one being that which is properly known as the Valley of Jezreel; a name, however, which is sometimes given to the whole plain. It is a deep plain, about three miles across, and has a rapid descent to the Jordan. The northernmost branch, between Little Hermon and Tabor, in its descent to the Jordan, opens to the N.E. into a side plain, as it were, distinguished by the mountain called the "Horns of Hattin," inclosed between the hills of Galilee, and those which immediately skirt the sea of Tiberias. The *Khurun Hattin*, or "Horns of Hattin," is a ridge about a quarter of a mile in length, and 30 or 40 feet high, terminated at each end by an elevated peak 20 or 30 feet higher. It is known to pilgrims as the Mount of the Beatitudes, the supposed scene of the Sermon on the Mount, though this is at least doubtful. The plain of Esdraelon is often mentioned in sacred history as the great battlefield of Jewish and other nations, under its various names of Megiddo, Jezreel, &c. Its adaptation for military contests has caused its surface to be frequently moistened with blood from the earliest periods of history down to our own time. It is noted for its great fertility, and is covered with the richest pasture, having here and there patches of cultivated land. It is sparsely inhabited, being almost without villages, which, however, occur on the slopes of the surrounding hills.

Tabor. Mount Tabor, in many respects the most remarkable mountain in Palestine, stands apart and alone on the N.E. border of the plain of Esdraelon. It is only about 1800 feet in height, but it commands an extensive and beautiful view of the surrounding country. As seen from the N.W., it towers like a dome; while from the E. it has the appearance of a long arched mound. The sides are mostly covered with bushes and oak and other trees; but the latter stand too far apart from each other for it to be what could properly be called a wooded hill. The top is an oval plain about a quarter of a mile in extent, containing ruins of ancient buildings. From the names of Tabor and

ermon. Hermon occurring together, it was taken for granted that they must lie near each other; and hence the latter name was identified with the hilly ridge about six miles south of Mount Tabor. There is no reason to suppose, however, that this mountain is ever referred to in Scripture as Hermon; and all the passages where that name occurs are applicable with greater strength and beauty to Hermon, the loftiest peak of the Lebanon Mountains. This one is therefore now commonly called the Little Hermon (*Dûhy* by the Arabs), and is a desert shapeless mass, with neither beauty nor fertility to excite the attention of the traveller. It is about 1860 feet in height, and sinks gradually down on the E. to a low ridge of table-land along the eastern part of the valley of Jezreel. Farther S. are the moun-

Gilboa. tains of Gilboa, constituting an elevated tract, with several ridges; in all about a league in breadth, and rising to the height of about 1300 feet. "The mountains of Gilboa seem yet to lie under the curse uttered by David in his lamentations, for the north side, the side on which 'the shield of the mighty was vilely cast away,' and where 'the beauty of Israel was slain,' presents a more barren appearance than is almost to be found in the land." (Van de Velde.)

South of the plain of Esdraelon, throughout to the borders of the southern desert, is an almost unbroken ridge of mountains or mountain tract, stretching from north to south, and nowhere less than from 25 to 30 miles in breadth. Towards the east it forms the precipitous western wall of the great valley of the Jordan and the Dead Sea; while towards the west it sinks down by an offset into a ridge of lower hills, which lie between it and the great plain along the coast of the Mediterranean. This mountainous country rises gradually from the plain of Esdraelon towards the south, until, in the vicinity of Hebron, it attains an elevation of nearly 3000 feet above the level of the Mediterranean. It comprises the districts of Judah and Samaria, between which, however, there is no distinct natural boundary, although they differ considerably in their general characteristics. Palestine.

The hills of Samaria are often beautifully wooded, and this region is more populous and better cultivated than any other part of Palestine. Towns and villages are scattered here and there in every direction among olive woods and vineyards. The principal mountains are those of Ebal and Gerizim, from which the solemn blessings and curses of the law were declared to the assembled hosts of Israel. They are separated from each other by a narrow valley, on each side of which they rise in rocky precipices to the height of about 800 feet, but from the general elevation of the country, they are 2500 feet above the level of the Mediterranean. In this narrow valley, in some parts only a few hundred feet in width, stood Shechem, whose site is now occupied by the modern Nablous—"a valley green with grass; gray with olives, gardens sloping down in all directions; at the end a white town embosomed in all this verdure, lodged between the two mountains which extend on either side of the valley—that on the south Gerizim, that on the north Ebal;—this is the aspect of Nablous, the most beautiful, perhaps it might be said the only very beautiful, spot in Central Palestine." (Stanley.) Shechem was the capital of the northern kingdom of Palestine after the separation, and Gerizim is the mountain to which the woman of Samaria referred when she said—"Our fathers worshipped in this mountain." The well here is almost the only special spot absolutely undisputed of all the localities associated with our Lord's life in Palestine. It is remarkable, that in the evangelic narratives we find so very little that serves to indicate the precise spots hallowed by the life of our Saviour. It seems as if an angelic tongue were still saying, "He is not here, but is risen"—"Why seek ye the living among the dead?" Samaria.

The mountains of Judea, although of greater historical celebrity, are less attractive in appearance than those of Samaria. They are rugged and generally uninteresting in their character, but eminently fitted for the abode of that tribe which was aptly described as a lion couching, and not to be roused up. "The tribes of the east and of the north were swept away by the Assyrian kings; Galilee and Samaria fell before the Roman conquerors; whilst Judah still remained erect, the last because the most impregnable of the tribes of Israel." (Stanley.) The hills of Judea are generally separated from one another by valleys and torrents, and are for the most part of moderate height, uneven, and seldom of any regular figure. The rock of which they are composed is easily converted into mould, which, being arrested by terraces, when washed down by the rains, renders the hills cultivable in a series of long narrow gardens formed by these terraces from the base upwards. Thus the hills were in former times clad most luxuriantly; but when the inhabitants were dispersed, and cultivation was abandoned, the terraces fell to decay, and the soil which had been collected on them was washed down into the valleys, leaving only the arid rock bare and desolate. This is the general character of the hills of Judea; but in some parts they are still wooded, and in others the ancient mode of culture is still retained, by which the traveller may now judge how productive the country must have once been. The features of desolation which have just been noticed are especially true of the northern part of Judea, forming the ancient territory of Benjamin. Its most favourably-situated mountains are wholly uncultivated, and perhaps in no other country is such a mass of rock exhibited without an atom of soil. In the east, towards the plain of Jericho, it takes a naturally stern and grand character, such as Judea

Palestine

no other part of Palestine offers. It is through this wild and melancholy region that the roads from Jerusalem to Jericho, and (by way of Wady Saba) to the Dead Sea, lie. It has hence by the former route often been traversed by travellers in their pilgrimages to the Jordan; and they unite in depicting it in the most gloomy hues. "The road," says Dr Olin, "runs along the edge of steep precipices and yawning gulfs, and in a few places is overhung with the crags of the mountain. The aspect of the whole region is peculiarly savage and dreary, vieing in these respects, though not in overpowering grandeur, with the wilds of Sinai. The mountains seem to have been loosened from their foundations, and rent in pieces by some terrible convulsion, and there left to be scathed by the burning rays of the sun, which scorches the land with consuming heat." These characteristics become more manifest on approaching the Jordan; and the wild region extending north of the road is believed, with sufficient probability, to form the "wilderness" where, after his baptism, Jesus "was led up" of the Spirit to be tempted of the devil, and where "he fasted forty days and forty nights." The lofty ridge which extends north of the road, and fronts the plain of Jericho, is called Quarantana, with reference to this event: and the particular summit from which Satan is supposed to have displayed to the Saviour "the kingdoms of the world and the glory of them," is crowned by a chapel still occasionally resorted to by the devouter pilgrims; while the eastern face which overhangs the plain is much occupied with cells and grottos, once the favourite abodes of pious anchorites. The Quarantana forms apparently the highest summit of the whole immense pile, and is distinguished for its sere and desolate aspect even in this gloomy region of savage and dreary sights. It is estimated to have an almost perpendicular height of 1200 or 1500 feet.

In the southern region, usually called in Scripture "the hill country of Judah," there are few mountains of a marked character, the peaks of the general ridge being of little apparent elevation, although actually much elevated above the sea-level. The most desolate part of the whole of this wild region seems to have been distinguished as "the wilderness of Judah," while "the mountains of Judah," or "the hill country of Judea," applies to the mountainous region south of Jerusalem, towards Hebron. To this district belongs the wilderness of Tekoa, and beyond it, eastward, "the wilderness of Engedi," Maon, and Ziph,—names made familiar to us by the history of David. To obtain a clear notion of this tract, we should view it from the great Arabah, beyond the southern extremity of the Dead Sea, whence it was surveyed by the Israelites when they contemplated entering the Promised Land from the south-east. The two terraces which, towards the south end of the Dead Sea on the east side, form the descent to its deep basin from the high lands of Judea, stretch off to the south-west; and the ascents from the plain to the first, and from the plateau of the first to the top of the second, which forms the general level of Judea, present to him who approaches from the lower region of the Arabah high mountain barriers, which he has to ascend by gorges or passes of more or less difficult ascent. After ascending from the great valley, the traveller passes over a wild district covered with rocky hills, till he comes to the frontier-wall of the first terrace or step, which was probably pre-eminently "*the* mountain of the Amorites." There are in this three principal passes, the southernmost being that of Nubeh-es-Sufah, the Zephath of Scripture, called also Hormah, which we know to have been the pass by which the Israelites attempted to enter Palestine from Kadesh when they were driven back. The top of this pass is said to be 1434 feet above the level of the sea. On reaching the top, a journey of three hours among hills of chalky limestone brings the traveller to the second great ascent to the general level of the hill country of Eastern Judea. This second ascent is similar to the first, but not more than half as high. This statement will convey some idea of that difficulty of military access to the country in this direction which eventually induced the invading Hebrews to take another and more circuitous route. In the direct south of Judah the approach is marked by an ascent more gradual, over a succession of less elevated plateaus, from the desert regions of sand and rock to the hills of Judah. Recent discoveries in that quarter have shown that much of the south border country, which was formerly regarded as desert, is in fact a variegated region, affording good pastures, into which the sheep-masters of Judah doubtless sent their flocks of old.

Jordan.

To the east of this mountain tract lies the valley of the Jordan, the most remarkable of all the known depressions of the earth, as well on account of its great length as of its almost incredible depth. It is around and along this deep fissure that the hills of Western and Eastern Palestine spring up, presenting on the one side a mass of green pastures and forests melting away on the east into the red plains of Haurân, and on the other a mass of gray rock rising above the yellow desert on the south, and bounded on the west by the long green strip of the maritime plain.

The source of the Jordan has given rise to so much uncertainty and doubt that we consider it necessary to go into the subject at some length. It is usual to refer the origin of a river to the remotest of its sources; but we occasionally find, particularly with respect to ancient rivers, that this is not the case—various accidental circumstances operating to give this distinction to some one of the less remote springs. This was doubtless the case here, for we can easily suppose that the Jews would be unwilling to seek for or to acknowledge that the sources of the Jordan lay beyond their own territory. Accordingly we find that Josephus and others place the source of this river at or in the vicinity of Bâniâs (the ancient *Paneas*). It there issues from a spacious cavern under a wall of rock at the base of the Heish Mountain. Directly over the cavern, and in other parts in the face of the perpendicular rock, niches have been cut, apparently to receive statues. Here Herod built a temple in honour of Augustus; and somewhat below there was a town, traces of which still remain. In one place Josephus carries its source still higher, stating that the waters which came out at the Paneas cavern issued from Lake Phiala, which lay 15 miles eastward, and which was the true source of the river. He relates that the tetrarch Philip cast some chaff into this lake, and that it came out at the Paneas cavern. Irby and Mangles, in travelling by a direct route from Damascus to Bâniâs in February 1818, came upon "a very picturesque lake, apparently perfectly circular, of little more than a mile in circumference." According to Dr Robinson's account, which differs in several respects from that of Irby and Mangles, it lies at the bottom of a deep bowl, apparently an ancient crater, about 150 or 200 feet below the level of the surrounding country. The water is stagnant and impure, with a slimy look. The singularity of this lake is, that it has no apparent supply or discharge, and its waters appeared perfectly still. The locality and appearance of this lake leave little doubt that it is the Phiala of Josephus—a deep round lake, like a bowl or cup, whence its name; but it is impossible to suppose that it can have any subterranean communication with the stream at Panias, for in order to that it must pass under a rivulet which lies apparently lower than the lake itself. The bright, limpid, sparkling waters of the former can have no connection with the dark, stagnant, slimy matter of the latter; and, indeed, to supply such a fountain would exhaust the lake in one day.

A second source of the Jordan, also described by ancient writers, is at a place called Tell el-Kâdy, about 2½ miles W. by N. from Bâniâs. The *Tell*, or hill, is a small oblong

Palestine. eminence on the plain, extending from E. to W. The western end appears as if built up with large trap boulders, and through these the water gushes out several feet above the base. It forms a little lake at the bottom, and then rushes down a steep channel to the next lower plateau. In the surface of the hill directly above is a cavity of some extent, into which the water also rises, and runs off as a considerable stream through a break in the edge of the Tell, tumbling down its south-western side, and afterwards joining the other stream. These streams form together the middle and largest arm of the Jordan, called Leddân; equal, indeed, in the volume of its water to both the other branches. The fountain at Tell el-Kâdy exactly corresponds to the source which Josephus speaks of as "the other source" of the Jordan, called also Dan, where stood the city of Dan, anciently *Laish*, belonging originally to the territory of Sidon, but captured by the Danites, and named after the founder of their tribe. The same city Dan is placed by Eusebius and Jerome at four Roman miles from Paneas. towards Tyre, corresponding well with the present distance of the sources. The river issuing from this source, Josephus says, was called "the Lesser Jordan," obviously in distinction to the somewhat longer stream from Paneas, into which it flows.

We find, however, that there is a source more remote than either of these, and one of which the ancients make no mention whatever. This is the stream coming from Wady et-Teim, called Nahr Hasbâny, which flows about a mile to the W. of Tell el-Kâdy. It rises 6 or 8 miles farther N., near the large village of Hasbeiya, and is afterwards joined in its course by a stream from Mount Hermon. The first who minutely described this source of the Jordan was Mr Thomson the missionary, whose account is to be found in the number of the *Bibliotheca Sacra* for February 1846. He says:—"*Sept. 20th*, 1843.—We left the palace of the emirs of Hasbeiya about sunrise, and in half an hour reached the fountain of Hasbâny. Our path led us across the bed of a winter torrent, which comes down from the mountains on the E. of Hasbeiya, and over a rocky hill covered with lava boulders. The fountain lies nearly N.W. from the town, and boils up from the bottom of a shallow pool some eight or ten rods in circumference. The water is immediately turned by a strong stone dam into a wide mill-race. This is undoubtedly the most distant fountain, and therefore the true source of the Jordan. . . . . . It meanders for the first 3 miles through a narrow but very lovely and highly-cultivated valley. Its margin is protected and adorned with the green fringe and dense shade of the sycamore, button, and willow trees; while innumerable fish sport in its cool and crystal bosom. It then sinks rapidly down a constantly deepening gorge of black basalt for about 6 miles, when it reaches the level of the great volcanic plain, extending to the marsh above the Lake Hûleh. Thus far the direction is nearly S., but it now bears a little westward, and in 8 or 10 miles it enters the Hûleh not far from its N.W. corner, having been immensely enlarged by the waters from the great fountains of Bâniâs, Tell el-Kâdy, el-Mellâhah, Derakit or Belât, and innumerable other springs. The distance from the fountain of Hasbâny to the lake cannot be less than 25 miles, and nearly in a straight direction. . . . . Although the channel immediately above the fountain of the Hasbâny is during most of the year dry and dusty, yet during the rainy season a great volume of water rushes down from the heights of Jebel esh-Sheikh, above Rasheiya, a distance of 20 miles, and unites with the water of this fountain. The stream is there so formidable as to require a good stone bridge, which is thrown across it a few rods below the fountain." A similar account of this source is given by Van de Velde and others who have since visited it. The former, who was there in 1852, says—"A little higher up the water is turned off by a large stone dam, and part of it is carried away in a small stream, which works a mill lower down. A few yards above is the basin or source where the water comes bubbling up from under steep projecting rocks. It is of a transparent dark colour, and appears to be of immense depth. But there was still something I did not understand: it appeared to me that the main stream of water came down from a point farther up; this made me doubt whether I really had before me the right source, until it was explained to me that this stream which I saw coming down from the N.E., above the source, was only a winter torrent, which, rising at Râsheiya, swells into a brook of no inconsiderable appearance, containing even more water than the Hasbâny source itself, but which, nevertheless, dries up entirely in summer, and then leaves the true source visible." The question as to the source of the Jordan is, whether we are to adopt that which has now been found to have the most remote origin, or to keep to that which the usage of all antiquity has sanctioned? Dr Robinson seems to be almost the only supporter of the latter view. "The attempt," he says, "to introduce a change at this late hour would be alike presumptuous and futile. As well might we require the majestic floods of the Mississippi and Missouri to exchange these names above their junction, inasmuch as the latter is, of the two, by far the longer and the mightier stream." It seems to us, however, that the sanction of ancient usage is not in this case so strong, nor has it been in modern times in so general use, as to lead us to depart from what is an all but universal rule. It was the general opinion till very recently, that the different sources did not commingle their waters until they met in the small lake now called Bahr el-Hûleh, the Merom of Scripture; but it has been found that they unite at some distance from the lake, and enter it in one stream.

Merom

The first of the three great lakes of the Jordan is the Bahr el-Hûleh, the Waters of Merom of the Old Testament, and the Lake Samochonitis of Josephus. Its dimensions are very variously stated, and they doubtless vary much at different times of the year. Dr Robinson estimates it to be about 4 or 5 miles in length, and not less than 4 in breadth at the northern end. Besides this, however, the lake was skirted on the N. by a marshy tract of equal or greater extent, covered with tall reeds and flags, but which in the rainy season is doubtless covered with water, and may therefore be properly regarded as forming part of the area of the lake. The basin of the lake is bounded on the W. by a high ridge of hills, and on the E. by a much lower ridge. The lake does not occupy the centre of the valley, but is much nearer to the eastern than to the western side. There is a space of about 5 miles between its shore and the western hills, but on the opposite side its border extends almost to the hills. The length of the basin is about 15 miles. The lake abounds in fish, and is the resort of numerous wild fowl. On quitting this lake the Jordan passes rapidly along the narrow valley, and between well-shaded banks, to the Lake of Gennesareth, called also the Lake of Tiberias or the Sea of Galilee, a distance of about 10 miles. In this part of its course it has a fall of nearly 400 feet, and is described as a continuous torrent rushing down in a narrow rocky channel between almost precipitous mountains. About 2 miles below Lake Hûleh is a bridge called Jacob's Bridge, and here the river is about 80 feet wide and 4 feet deep.

Sea of Galilee.

The Sea of Galilee, called in the Old Testament the Sea of Chinnereth, is the second of the three great lakes of the Jordan. It is situated in a deep basin, more than 1000 feet below the level of the surrounding country, and 328 feet below the level of the Mediterranean. It is about 13 miles in length by 6 in breadth, and is surrounded by lofty and precipitous hills. Though thus sheltered, it is yet liable to sudden and dangerous storms; the wind, when violent, coming down almost perpendicularly upon its sur-

face, and ploughing it up into huge waves. It was in one of these storms that the disciples were overtaken, and in danger of perishing, when Jesus came to them walking on the sea. The barrenness of the surrounding mountains, and the total absence of wood, give an aspect of dulness to the scenery; and this impression is heightened by the dead calm and the silence which reigns over the wide expanse of its surface. Its waters are very clear and sweet, and contain various species of excellent fish in great abundance. The borders of the lake were in the time of Christ well peopled, being covered with numerous towns and villages, but now they are almost desolate, and the fish and water-fowl are but little disturbed. When visited by the American expedition in 1848, there was only one small frame-boat on the lake, used merely to bring wood across from the opposite side. On the shore of this lake stood Capernaum, where Jesus dwelt; Bethsaida and Chorazin, where many of his mighty works were done; Magdala, the residence of Mary Magdalene; and Tiberias, which had only just then been built by Herod Antipas, and was beginning to rise into importance. Along its banks the depth of its situation produces a tropical vegetation unknown in the hills above. Fertility is everywhere more or less apparent in the thin strip of land which intervenes between the mountains and the lake. On its western side the mountains recede suddenly inland, leaving an open level plain, now called el-Ghuweir, and anciently "the land of Gennesareth." Josephus speaks of this plain as a place of wonderful fertility, abounding with fig-trees, walnuts, olives, and palms, and producing the principal fruits all the year round, and grapes and figs during ten months of the year. Though this description is evidently exaggerated, Dr Wilson says that "the valley has every appearance of the greatest fertility; and when kept in order and properly laid out, would be truly beautiful and delightful. At present it has some rich pasturage and cultivated fields, bearing luxuriant crops of corn, rice, and vegetables. Wild figs and quantities of the nakb tree are still found growing in it in several places. Various lines of oleanders, particularly along the streams which run through it, add to its beauty. The soil is of a dark alluvial loam, and contains the *debris* of the basaltic rock in the neighbourhood." This tract is definitely bounded by the hills which run down to the lake on the S. and N. of it, at Mejdel and at Khân Minyeh. It is about 3 English geographical miles in length, by 2 in breadth. "No less than four springs pour forth their almost full-grown rivers through the plain." (Stanley.)

From the Sea of Galilee to the Dead Sea the direct distance is only about 60 miles, but by reason of its many windings the Jordan has here a length of more than 200 miles. In this distance it has a fall of nearly 1000 feet. This portion of the river was explored by Lieut. Molyneux, of H.M.S. Spartan, in 1847, and an account of the expedition is given in the *Royal Geographical Society's Journal* for 1848. On leaving the Sea of Tiberias they found the river to be upwards of 100 feet in breadth, and 4 or 5 feet deep. In many parts it was split up into a number of small streams, with little water in any of them, and occasionally the boat had to be carried upwards of 100 yards over rocks and through thorny bushes. In other places it had to be carried on the backs of the camels for some distance, the stream being quite impracticable. At its upper end the *ghor*, or great valley of the Jordan, is about 8 or 9 miles broad, and this space is anything but flat—nothing but a continuation of bare hills, with yellow dried-up weeds, which look at a distance like corn-stubbles. These hills, however, sink into insignificance when compared to the ranges of mountains which inclose the ghor, and it is therefore only by comparison that this part of it is entitled to be called a valley. Within this broader valley is a smaller one on a lower level, through which the river flows. After passing el-Buk'ah, the Jordan forms two branches, which inclose an oval-shaped island about 5 or 6 miles in circumference. Here its winding course is marked by luxuriant vegetation, and the ghor or valley now begins to assume a much better and more fertile aspect. It appears to be composed of two different platforms; the upper one on either side projects from the foot of the hills which form the great valley, and is tolerably level, but barren and uncultivated. It then falls away in the form of rounded sand-hills or whitish perpendicular cliffs, varying from 150 to 200 feet in height, to the lower plain, which is properly the valley of the Jordan. The river here and there washes the foot of the cliffs which inclose this smaller valley, but generally it winds in the most tortuous manner between them. In many places these cliffs are like walls. About this part the lower plain is about a mile and a half or two miles broad, and full of the most rank and luxuriant vegetation, like a jungle. At Attah the lower valley breaks out into a magnificent plain, extending from the foot of the hills on either side across the ghor, but with a steep western side, where the large Arab village of Beisan stands. On reaching the top of this high western ridge, the country southward, as far as the eye could see, was fertile, well watered, and thickly inhabited. Hundreds of small sheds might be seen studded on the plain, with men watching the crops (chiefly Indian corn), and slinging stones to keep off the birds. "I think," says Lieutenant Molyneux, "the view from this point over the valley of the Jordan was one of the finest things I had seen; an abundant vegetation extending up the slopes of the eastern hills, which are crowned with trees up to the summit, and everything growing in the wildest luxuriance; while on the western side the higher steppe breaks down into steep sand-hills or whitish perpendicular cliffs, with only here and there the means of ascent. The river as usual winds very much, with banks about 20 feet in height, of brown clayey soil, somewhat resembling those of the Thames, and for some distance on either side a thick and almost impenetrable jungle." Such is the general character of the Jordan valley to the Dead Sea,—sometimes lofty perpendicular cliffs or sand-hills inclose the river on each side, at other times they recede to a considerable distance, and leave an extent of jungle or fertile plain. The valley seemed to contain a considerable population. Next year (1848) an American expedition, under the command of Lieutenant Lynch, U.S.N., likewise explored this portion of the valley of the Jordan. The account given by this expedition does not differ materially from that furnished by Lieutenant Molyneux, except that the river in the former case was greater, being in April, whereas in the latter case it was in August. "The great secret," says Lieutenant Lynch, "of the depression between Lake Tiberias and the Dead Sea is solved by the tortuous course of the Jordan. In a space of 60 miles of latitude, and 4 or 5 miles of longitude, the Jordan traverses at least 200 miles. The river is in the latter stage of a freshet; a few weeks earlier or later, and the passage would have been impracticable. As it is, we have plunged down twenty-seven threatening rapids, besides a great many of lesser magnitude."

Plain of Jericho.

The valley of the Jordan is generally not more than about 8 miles in width, but immediately above the Dead Sea the hills on either side recede, leaving a plain about 12 miles in breadth. This is the plain of Jericho, now partly desert, but, from the abundance of water and the heat of the climate, susceptible for the most part of being rendered in the highest degree productive. Indeed, its fertility has been celebrated in every age. Josephus, whenever he has occasion to mention Jericho, rarely fails to break forth into praises of the richness and productiveness of its environs. He calls it the most fertile tract of Judea; pronounces it a divine region; and, in speaking of the fountain, says it watered a tract 70 stadia long by 20 broad, covered with

Palestine. beautiful gardens and groves of palms of various species. The Scriptures call Jericho the "city of palm trees;" and Josephus describes these graceful trees as here abundant and very large, and growing even along the banks of the Jordan. This region also produced honey, opobalsam, the cypress tree (or *el-henna*), the sycamore, and myrobalanum, as well as the common fruits of the earth, in great abundance. Of all these productions few are now to be seen. The groves of palm trees have disappeared; even the one solitary remnant noticed by recent travellers has, within the last few years, taken its departure. The sycamore, too, has retired from the plain, and the opobalsam is no longer known in the country. Honey, if found at all, is now comparatively rare, and the cypress tree has entirely disappeared. The myrobalanum alone appears to thrive, being probably the thorny shrub growing wild in the plain to which the name of *zŭkkûm* is given by the Arabs. It produces a green nut, from the kernel of which is extracted the oil known in the present day as the "balsam of Jericho."

Dead Sea. The Dead Sea (called in Scripture the Salt Sea, the Sea of the Plain or the Arabah, and the Eastern Sea; by Josephus, the Asphaltic Lake, λίμνη Ἀσφαλτίτης; and by the Arabs, *Birket Lut*, "Sea of Lot"), is the largest as well as the most remarkable of the lakes of Palestine. It is about 39 or 40 geographical miles in length from north to south, and 9 or 10 wide from east to west. It lies deeply embedded between, on the western side, lofty cliffs rising to the height of about 1500 feet, and on the eastern, high mountains, the loftiest ridges of which are estimated to be from 2000 to 2500 feet above the sea. The northern shore of the lake, as described by Lynch, is an extensive mud flat, with a sandy plain beyond; and the north-western an unmixed bed of gravel coming in a gradual slope from the mountains to the sea. The eastern coast is a rugged line of mountains, bare of all vegetation,—a continuation of the Haurân range coming from the north, and extending south beyond the scope of vision, throwing out three marked and seemingly equidistant promontories from its south-eastern extremity. At the south-western extremity of the lake is the isolated ridge called the Mountain of Usdom, containing fossil salt. The bottom consists of two submerged plains, an elevated and a depressed one,—the southern averaging about thirteen, and the northern about thirteen hundred feet below the surface. The well-defined promontory on its eastern side marks the extent of each of these plains. The old stories about the pestiferous qualities of the Dead Sea are mere fables. Birds are observed flying over the sea, and even resting upon its waters, without being injured; and Dr Robinson was five days in the vicinity without perceiving any noisome smell or noxious vapour arising from the lake. The uncommon saltness of the water, however, renders it speedily destructive to any fish that may be brought down by the streams; but it is asserted that there is one small species of fish peculiar to it. The quantity of salt, too, that is constantly given off in small particles is equally destructive to vegetation on its shores. Everything along the shore is covered with a white incrustation of salt. "Strewn along its desolate margin lie the most striking memorials of this last conflict of life and death; trunks and branches of trees, torn down from the thickets of the river-jungle by the violence of the Jordan, thrust out into the sea, and thrown up again by its waves, dead and barren as itself." (Stanley.) (See ASPHALTITES.)

The deep depression of the Dead Sea below the level of the Mediterranean appears never to have been suspected till the time of its actual discovery in 1837, when Messrs Moore and Beek, then engaged in surveying it, were led to examine the question of its comparative elevation. Since that time various barometrical observations have been made, but they differ considerably from each other. The trigonometrical observations of Lieutenant Symonds of the British Royal Engineers are the most reliable that we yet possess, and they give its depression at 1312·2 feet below the level of the Mediterranean, which corresponds very closely with that obtained by Mr Henry Poole in 1855 with the *anéroid métallique*,—namely, 1313·5 feet.

It was long believed that this lake did not exist before the destruction of Sodom and the other "cities of the plain," and that before that time the Jordan continued its course through the great valley of Arabah, which extends from the Dead to the Red Sea. The fact, however, of the former being above 1300 feet lower than the latter, and the discovery of a ridge of high land, about 400 feet above the level of the sea, stretching directly across this valley, render this hypothesis extremely improbable. Even supposing that this ridge may be of recent formation, and that the depression of the Jordan valley has taken place since that time, we have yet, from Lake Hûleh where the depression commences, to the Red Sea, a direct distance of nearly 300 miles, with a fall of only about 50 feet. It seems more likely that the fertile and well-watered district in which stood the "cities of the plain," was that southern portion of the lake which is at present submerged under some 13 feet of water. It seems, too, to be the salt rocks around this portion that give to the waters their present deadly qualities.

Though there is every reason to believe that the Dead Sea has existed here from the earliest times that we have any account of the country, it is impossible to suppose that it was in its present depressed state at the time when "Lot lifted up his eyes, and beheld all the plain of Jordan, that it was well watered everywhere, before the Lord destroyed Sodom and Gomorrah, even as the garden of the Lord." The appearance of the district itself, with its numerous evidences of active volcanic agency,—its bitumen, sulphur, nitre, lava, &c.,—render this view extremely likely. "The bituminous and sulphureous sources of the Dead Sea," says Volney, "the lava, the pumice-stones thrown upon its banks, ... demonstrate that the seat of a subterraneous fire is not yet extinguished. Clouds of smoke are often discovered to rise from the lake, and new crevices to be formed on its shore." Lieutenant Lynch unexpectedly found between the Jabbok and the Dead Sea a sudden break-down in the bed of the Jordan. He says, that "if there be a similar break in the water-courses to the south of the sea, accompanied with like volcanic characters, there can scarce be a doubt that the whole ghor has sunk from some extraordinary convulsion, preceded most probably by an eruption of fire and a general conflagration of the bitumen which abounded in the plain. Whether this great depression took place at once on the destruction of the cities of the plain, or has been going on gradually since that time, is very doubtful. The latter hypothesis, however, seems the more probable. The accounts given by modern travellers of the River Jordan differ in many respects from the character that we form of it from the notices that occur in Scripture. In the latter case, we figure to ourselves a considerable river moving majestically along its course, having few fords, and periodically overflowing its banks. On the other hand, we have an impetuous torrent, with no proof of its overflowing its banks, and in many places without sufficient water to float a boat of light draught. Molyneux, in speaking of the upper part of its course, says,—"I am within the mark when I say that there are many hundreds of places where we might have walked across without wetting our feet, on the large rocks and stones." These accounts can easily be reconciled if we suppose that formerly the depression of the Dead Sea and the lower course of the Jordan was much less than at present, and that consequently it had a slower course, and a considerably larger volume of water.

It is now generally believed to be most probable that,

Palestine. anterior to the historical period, the whole valley, from the base of Hermon to the Red Sea, was once an arm of the Indian Ocean, which has gradually subsided, leaving the three lakes in its bed, with their connecting river. According to Captain Newbold, in the *Journal of the Royal Asiatic Society*, vol. xvi., "The valley of the ghor, which is a vast longitudinal crevasse in calcareous and volcanic rocks, extending from the southern roots of Libanus and Anti-Libanus, to the Gulf of Akaba, from 1000 to 2000 feet deep, and from 1 to 8 miles broad (this is understated), appears to have been caused by the forcible rending and falling in of the aqueous strata resulting from the eruption of the basalt, which bases it almost from its commencement to the Dead Sea. . . . . Watery corrosion or abrasion can have had little influence in its formation. The great alterations in its surface commenced prior to the historic period, and terminated probably in the catastrophe of Sodom." See also an article on this subject in the *Royal Geographical Society's Journal*, vol. xxiii. (1853), by Captain W. Allen, R.N., who, from indications of alluvial deposit on the sides of the mountains around the Dead Sea and lower portion of the Jordan, apparently marking the gradual subsidence of the waters in this district, came to the same conclusion. As, however, these indications seem to be entirely confined, as regards the Dead Sea, to its northern portion, and as their appearance would seem to indicate a time more recent than that claimed for that state of the country, we are inclined to consider it rather as an indication of the gradual sinking of the basin of the Dead Sea subsequently to the destruction of the cities of the plain.

Minor streams. Besides the Jordan, Palestine possesses scarcely another river of any size. Most of those that are laid down in the maps, or whose names figure in history, are merely torrents or water-courses, which carry off the waters in the rainy season, or, if they have their origin in springs, are spent in the season of drought soon after they quit their sources. There are, however, numerous springs, which in a country like this are of the greatest importance to cultivation. The Kishon, the river on whose banks the army of Sisera was overthrown, is in winter and spring a large and rapid river, flowing from Mount Tabor, and collecting the waters of a large part of the plain of Esdraelon and its bordering hills; but in summer all the part which passes over the plain is quite dried up, and only water from perennial springs in Carmel is then found in the last seven miles of its bed. It enters the Bay of Acre near the foot of Mount Carmel. The Kishon, says Van de Velde, "is considered, on account of its quicksands, the most dangerous river in the land;" and hence Deborah and Barak, in their song of victory, sang—"The River Kishon swept them away; that ancient river, the River Kishon." They that fled had to cross the bed of the torrent; but the Lord sent a heavy rain; the waters rose; the warriors stumbled, and fell into the quicksands, and the waves which came rushing on washed them away into the sea. The Belus, now called *Nahr Kardanus*, falls into the Bay of Acre higher up than the Kishon. It is a small stream, fordable even at its mouth in summer. It is not mentioned in the Bible, and is chiefly celebrated for the tradition, that the accidental vitrefaction of its sands taught men the art of making glass. The chief of the other streams that fall into the Mediterranean are,—the Zerka, about 3 miles N. of the ruins of Cæsarea, and supposed to be identical with the Crocodile River of Pliny; the Nahr el-Kasab, about 12 miles S. of Cæsarea, supposed to be the River Kanah of Scripture; the Nahr el-Arsouf, about 10 miles S. of this last, and about the same distance N. of Joppa, chiefly noted for a celebrated castle of the same name which stood near its mouth in the time of the Crusades; the Nahr-Abi-Petros, a little to the N. of Joppa, and the Nahr el-Rubin, 12 miles S. of that town; a brook about a mile and a half S. of Ashdod, which appears to be the Sorek of Scripture, and between Askelon and Gaza, two small streams, whose names are unknown; the Wady Gaza, 2 or 3 miles S. of the town of that name, which seems to be the Bezor of Scripture; and the brook el-Arish, which is supposed to be the river of Egypt which formed the southern boundary of the coast of Palestine. The most important tributaries of the Jordan and the Dead Sea are the Jarmuk, the Jabbok, and the Arnon. The first of these, called also Mandhur (the *Hieromax* of ancient geography), joins the Jordan about 5 miles below the Lake of Gennesareth. Its source is ascribed to a small lake, about a mile in circumference, lying 30 miles E. of the Jordan. It is a beautiful stream, and brings down a considerable body of water. The Jabbok, now called the Zerka, is a narrow, but deep and rapid stream, which joins the Jordan about half-way between Gennesareth and the Dead Sea. The Arnon, now the Wady Modjeb, is an affluent of the Dead Sea, and often mentioned in Scripture. The brook Kedron flows through the valley of Jehoshaphat, on the E. side of Jerusalem, to the Dead Sea. It is at present nothing more than the dry bed of a winter torrent, and even in that season there is no constant flow of water. The resident missionaries assured Dr Robinson that they had not during several years seen a stream running through the valley. It, however, bears marks of being occasionally swept over by a considerable volume of water.

Eastern Palestine. Of the region beyond the Jordan we know very little, as it has been seldom visited by travellers, partly on account of the insecure nature of the country, and partly also from the slight historical interest that attaches to it in comparison with Western Palestine. "The mountains rise from the valley of the Jordan to the height, it is believed, of 2000 or 3000 feet, and this gives them, when seen from the western side, the appearance of a much greater actual elevation than they really possess, as though they rose high above the mountains of Judea on which the spectator stands. As they are approached from the ghor, the horizontal outline which they always wear when seen from a distance is broken; and it is described, that when their summits are attained, a wholly new scene bursts upon the view, unlike anything which could be expected from below—unlike anything in Western Palestine. A wide table-land appears, tossed about in wild confusion of undulating downs, clothed with rich grass throughout, and in the northern parts with magnificent forests of sycamore, beech, terebinth, ilex, and enormous fig trees. . . . . The vast herds of wild cattle, now seemingly extinct, but which then wandered through those woods,—as those of Scotland through its ancient forests,—were in like manner at once the terror and pride of the Israelite—'the fat bulls of Bashan.' Flocks, too, there were of every kind—'rams, and lambs, and goats, and bullocks, all of them fatlings of Bashan.'" (Stanley.) Mr Buckingham describes with equal delight and admiration the varied beauties of this romantic region, the Decapolis of the Romans, the seat of ten renowned cities, famed for wealth and refinement, but now a scene of desolation, over which the wild Arab ranges with his flocks in quest of pasture or of prey. The country, according to the account of this traveller, is of extraordinary richness, abounding in the most beautiful prospects of thick forests, verdant slopes, and extensive plains. The landscape alone varied at every turn, and gave new beauties from every different point of view. "The general face of this region," he adds, "improved as we advanced farther into it; and every new direction of our path opened upon us views which surprised and charmed us by their grandeur and their beauty. Lofty mountains gave an outline of the most magnificent character; flowing beds of secondary hills softened the romantic wildness of the picture; gentle slopes, clothed with wood, gave a rich variety of tints hardly to be imitated by the pencil; deep valleys, filled with murmuring

streams and verdant meadows, offered all the luxuriance of cultivation; and herds and flocks gave life and animation to scenes as grand, as beautiful, and as highly picturesque, as the genius or taste of a Claude could either invent or desire." To the south, on the eastern shore of the Dead Sea, is found the bleak, barren, and mountainous district of Carac, where are the ruins of Rabboth-Moab, the ancient capital, and formerly a populous and an important place. Farther to the north is a vast plain of table-land, stretching southward from Damascus, not watered by any great river, yet rendered fertile by the industry of the inhabitants, who collect the rain-water into ponds for the purpose of irrigation, and thus contrive to raise large crops of grain. Of these countries, Haurân is the most celebrated for its luxuriant harvests of wheat; and the undulations of the ripened grain on its extensive fields have been compared to the rolling waves of the ocean. Many hummocks are seen scattered over the plain, the sites generally of deserted villages. All these hummocks, and every stone found in the field,—all the building stones, and the whole mountains of Haurân,—consist of basalt; and the houses being entirely built of this stone, even to the door-posts, present rather a sombre appearance. The beauty and fertility of this region is said to far exceed that of Western Palestine. It was pre-eminently "a place for cattle;" and on this account it was coveted by Reuben and Gad and the half tribe of Manasseh.

Scenery.

The high terms of admiration in which most travellers speak of the scenery of Palestine are evidently beyond the truth. "As a general rule," says Mr Stanley, "not only is it without the two main elements of beauty—variety of outline, and variety of colour—but the features rarely so group together as to form any distinct or impressive combination. The tangled and featureless hills of the lowlands of Scotland and North Wales, are perhaps the nearest likeness accessible to Englishmen of the general landscape of Palestine south of the plain of Esdraelon. Rounded hills, chiefly of a gray colour,—gray partly from the limestone of which they are all formed, partly from the tufts of gray shrub with which their sides are thinly clothed, and from the prevalence of the olive,—their sides formed into concentric rings of rock, which must have served in ancient times as supports to the terraces, of which there are still traces, to their very summits; valleys, or rather the meetings of these gray slopes, with the beds of dry water-courses at their feet—long sheets of bare rock laid, like flagstones, side by side along the soil; these are the chief features of the greater part of the scenery of the historical parts of Palestine. In such a landscape the contrast of every exception is doubly felt. . . . . The eye rests with peculiar eagerness on the few instances in which the gentle depressions become deep ravines, as in those about Jerusalem, or those leading down to the valley of the Jordan; or in which the mountains assume a bold and peculiar form, as Lebanon and Hermon, at the head of the whole country, or Tabor, 'Nebi-Samuel,' and the 'Frank Mountain,' in the centre of the hills themselves." On entering Palestine, he was struck with "the western, almost the English, character of the scenery. Those wild uplands of Carmel and Ziph are hardly distinguishable (except by their ruined cities and red anemones) from the lowlands of Scotland or of Wales; the cultivated valleys of Hebron (except by their olives) from the general features of a rich valley in Yorkshire or Derbyshire."

Ruins.

"Above all other countries in the world, it is a *land of ruins*. It is not that the particular ruins are on a scale equal to those of Greece or Italy, still less to those of Egypt. But there is no country in which they are so numerous, none in which they bear so large a proportion to the villages and towns still in existence. In Judea it is hardly an exaggeration to say that, whilst for miles and miles there is no appearance of present life or habitation, except the occasional goat-herd on the hill-side, or gathering of women at the wells, there is hardly a hill-top of the many within sight which is not covered by the vestiges of some fortress or city of former ages." "The ruins we now see are of the most diverse ages; Saracenic, crusading Roman, Grecian, Jewish, extending perhaps even to the old Canaanitish remains before the arrival of Joshua." "In the rich local vocabulary of the Hebrew language, the words for sites of ruined cities occupy a remarkable place. Four separate designations are used for the several stages of decay or of destruction which were to be seen even during the first vigour of the Israelite conquest and monarchy." (Stanley.) On this subject we cannot refrain from adducing the testimony of the Rev. J. L. Porter regarding the existing ruins in Eastern Palestine. "I had often read," he says, "how God had delivered into the hands of the children of Manasseh, Og, King of Bashan, and all his people; and I had observed the statement, that a portion of his territory, even the region of Argob, contained *threescore* cities fenced with high walls, gates, and bars, besides unwalled towns a great many. I had sometimes turned to my atlas, where I found the *whole of Bashan* delineated, and not larger than an ordinary English county. . . . . That *sixty walled cities*, besides unwalled towns a great many, should be found at such a remote age, far from the sea, with no rivers and little commerce, appeared quite inexplicable. Inexplicable and mysterious though it appeared, it was strictly true. On the spot, with my own eyes, I had now verified it. *Lists of more than a hundred* ruined cities and villages in these mountains alone I had tested and found correct, though not complete. More than thirty of these I had myself either visited or observed so as to fix their positions on the map." (*Five Years in Damascus*, 1855.)

Geology.

The mountains of Palestine are chiefly composed of an oolitic limestone, of a whitish or light gray colour, and abounding in caverns, to which frequent allusion is made in Scripture. In many places the limestone is covered with chalk rocks, containing layers and detached masses of flint, as well as corals, shells, &c. Masses of black basalt occasionally occur in the N. of Galilee, but are more common on the eastern side of the Jordan, and about the Dead Sea. In the valley of the Jordan, and especially about the Dead Sea, we have unmistakeable indications of volcanic action; and even in the northern portion of the valley, and about the sources of the river, these are much more numerous than was formerly supposed. Such indications, however, do not seem to have been discovered in other parts of the country, but earthquakes are not unfrequent. At Tiberias, the Dead Sea, and other parts of the valley, hot springs occur, many of which have a sulphureous taste or odour. Lava is found about the Dead Sea, the Sea of Tiberias, and other parts of the Jordan valley. At Béisan, Dr Robertson writes, "the whole region here is volcanic, like that around and above the Lake of Tiberias;" and Mr Buckingham, while crossing the River Hieromax, in his journey to Nazareth, observed that the dark masses of rock over which it took its course resembled a stream of cooled lava.

Minerals.

Of the mineral resources of the country little is known. Iron is abundant in several parts, but it is almost the only metal that is known to exist. Some traces of silver have been found. Near the sources of the Jordan there are rich mines of asphaltum, and large portions of this mineral are occasionally washed up by the Dead Sea. Salt is very abundant in the neighbourhood of the Dead Sea; and sulphur, nitre, and pumice are found there.

Climate.

The climate of Palestine is temperate, and much less changeable than ours. The variations of sunshine and rain, which with us extend throughout the year, are there unknown, the year being divided into a rainy season, com-

prising the latter part of autumn and the winter, and a dry season, comprising the rest of the year, when the sky is almost uninterruptedly cloudless, and rain very rarely falls. The rainy season usually commences about the end of October or beginning of November, not suddenly, but by degrees, and with occasional intervals of two or three days of fine weather. During the months of November and December the rains continue to fall heavily, and afterwards less so, and at longer intervals, till the end of March or beginning of April, when they entirely cease. The early and the latter rains mentioned in Scripture seem to have been the first showers of autumn and the later showers of spring. In summer the absence of rain soon destroys the verdure of the fields, and gives to the general landscape the aspect of drought and barrenness. In autumn the whole land becomes dry and parched, the cisterns are nearly empty, and all nature, animate and inanimate, looks forward with longing for the return of the rainy season. Snow falls more or less in winter, but the cold is not severe, and the ground is never frozen. In the higher parts, as at Jerusalem, it often falls to the depth of a foot or more, but it never lies long upon the ground. Thunder and lightning are frequent in winter. In the plains and valleys the heat of summer is very oppressive, but not in the more elevated tracts, as at Jerusalem, except when the south wind (sirocco) blows.

Fertility. The question as to the fertility of Palestine, so long agitated, has been satisfactorily set at rest by the investigations of recent travellers. In the scarped rocks and ruined terrace-walls that are everywhere seen in the hilly parts of the country, and in the remains of aqueducts and other means of artificial irrigation, we have ample evidence that the country was formerly in the highest state of cultivation; and we find that even now, with the present rude appliances of husbandry, the land, where cultivated, produces abundant crops. All travellers testify to the magnificence of the crops that are raised in the country. In Dr Robinson's works frequent notice is taken of this subject. In one place he speaks of the heavy crops of wheat and barley reminding him of the rich harvest he had seen a year before in Lincolnshire; and in another place he says that he passed through, in the north of Galilee, "fields of wheat of the most luxuriant growth, finer than which I had not before seen in this or any other country." (*Later Researches.*) "No soil," says Schubert, "could be naturally more fruitful and fit for cultivation than that of Palestine, if man had not destroyed the source of fertility by annihilating the former green covering of the hills and slopes, and thereby destroying the regular circulation of sweet water, which ascends as vapour from the sea to be cooled in the higher regions, and then descends to form the springs and rivers; for it is well known that the vegetable kingdom performs in this circulation the function of capillary tubes. But although the natives, from exasperation against their foreign conquerors and rulers (Pliny, *Hist. Nat.* xii. 54), and the invaders who have so often over-ruled this scene of ancient blessings, have greatly reduced its prosperity, still I cannot comprehend how, not only scoffers like Voltaire, but early travellers, who doubtless intended to declare the truth, represent Palestine as a natural desert, whose soil never could have been fit for profitable cultivation. Whoever has seen the exhaustless abundance of plants on Carmel and the border of the desert, the grassy carpet of Esdraelon, the lawns adjoining the Jordan, and the rich foliage of the forests of Mount Tabor—whoever has seen the borders of the lakes of Merom and Gennesareth, wanting only the cultivator to entrust to the soil his seed and plants,—may state what other country on earth, devastated by two thousand years of warfare and spoliation, could be more fit for being again taken into cultivation."

The vegetable productions of Palestine, owing to the diversified nature of the surface and climate, are considerably varied in their character. The trees, however, are almost all of small size, and extensive forests are unknown. **Productions.** The stately cedars of Lebanon, so often mentioned in Scripture, were not, properly speaking, trees of Palestine. They were always confined to the Lebanon range, and at present they are only to be found in one small hollow on its north-western slope. They are from 60 to 80 feet in height, with wide-spreading branches, and a trunk sometimes nearly 40 feet in circumference. The olive, the fig, and the pomegranate are the common trees of the country; but they are all so small as scarcely to attract the eye of the spectator till he is in the midst of them. The olive, which was, and still continues to be, the principal tree of Palestine, rarely rises to the height of more than 20 or 30 feet, but its branches are numerous and widely extended. It was an object of special culture by the Jews, on account of the valuable oil obtained from it. The fig tree was also extensively cultivated, and plantations of it still sometimes cover large tracts of country. The pomegranate was largely cultivated in the gardens and orchards of Palestine, and is frequently referred to in Scripture. It is a thick bushy tree, with thorny twigs, and rises to the height of about 20 feet. The palm tree, which in Scripture times was so common in Palestine, is now rarely to be seen. "Two or three in the garden of Jerusalem, some few perhaps at Nablous, one or two in the plain of Esdraelon, comprise nearly all the instances of the palm in Central Palestine." (Stanley.) It is still, however, not uncommon on the maritime plains. The terebinth, or turpentine tree, is one of the most common of the forest trees, though the name does not occur in our English Bibles. It is supposed to be that indicated by the Hebrew word אֵלָה, which is variously rendered in our version, oak, plain, teil tree, &c. The oak, indeed, is found in Palestine, but the name occurs more frequently in our version than in the original, and suggests the idea, that it was much more common and conspicuous in Palestine than it really was. There are several species of this tree to be found, but they are all of small size. It is still abundant in Bashan, remarkable for its size among the trees of Palestine. Among the other trees of Palestine may be mentioned the sycamore, mulberry, pine, pistachio, laurel, cypress, myrtle, almond, apricot, walnut, apple, pear, orange, lemon, &c.

The vine appears to have been cultivated in all parts of Palestine, probably with the exception of the low and hot valley of the Jordan. The hilly country of the north, and the elevated region of Judea, were, however, its chief seats. Hebron, according to the Jewish tradition, was the primeval seat of the vine; and at present the grapes of Hebron are the finest in Palestine. The region around this town abounds with vineyards, which frequently rise in successive terraces on the hill-sides. Each has still its round or square watch-tower of stone, from 10 to 15 or 20 feet high, in which keepers are stationed to protect the fruit from injury or pillage during the season of the vine. Grapes may always be had after June, but the regular vintage does not begin until the middle of September, and is not over everywhere until the middle of November.

Though deficient in trees, Palestine abounds with shrubs and wild flowers; indeed, the number of aromatic shrubs and fragrant flowers that are everywhere to be met with has been a subject of general remark among travellers. "My report," says Schubert, "would become a volume were I to enumerate the plants and flowers which the season exhibited to our view, for whoever follows the comparatively short course of the Jordan from the Dead Sea northward along the borders of Gennesareth and Merom, and onward to the utmost springs in Anti-Libanus, traverses in a few days climates, zones, and observes varieties of plants,

Palestine. which are in other countries separated by hundreds of miles. . . . . . . Whoever desires views, really extensive and beautiful, of lilies, tulips, hyacinths, and narcissuses, must, in the spring season, visit the districts through which we passed, where even the garlic assumes a size and beauty which might render it worthy of becoming an ornamental plant in our gardens." Among this profusion of wild flowers there is a peculiar blaze of scarlet imparted to the landscape by the prevalence of red flowers, chiefly anemones, wild tulips, and poppies. "Of all the ordinary aspects of the country, this blaze of scarlet colour is perhaps the most peculiar; and to those who first enter the Holy Land it is no wonder that it has suggested the touching and significant name of 'the Saviour's blood-drops.'" (Stanley.)

In the time of the patriarchs, and when first occupied by the children of Israel, Palestine was a pastoral country. As the people became settled and increased in numbers, agriculture came in for a share of attention, and the flocks and herds were sent to the wildernesses and other places not suited for cultivation; but throughout at least Old Testament times we have abundant evidence that pasturage continued to be a favourite and a principal pursuit with the Jewish people. Hence the frequent allusions that occur in Scripture to pastoral life. The plains and valleys everywhere abound with the most luxuriant pastures, and even the hilly portions, where vegetation is more scant, are well adapted for the numerous flocks of sheep and goats which still constitute the chief wealth of the people. Most of the present inhabitants, like the early settlers, are nomadic, wandering about from place to place with their flocks as the season or the state of the herbage demand. In summer, when the plains are parched with drought and every green herb is dried up, they proceed to the mountains or banks of the rivers; and in winter and spring, when the rains have re-clothed the plains with verdure and filled the water-courses, they return.

The chief of the agricultural productions are wheat and barley, of which the country, as already mentioned, yields most abundant crops. Maize and rye are also common, and rice is produced on the marshy borders of Lake Hûleh and upper parts of the Jordan. Pease and beans of several species are grown, and in some parts the potato has been introduced. Hemp is more commonly grown than flax; and in favourable localities cotton is largely cultivated. Among the other productions are madder, indigo, and tobacco; and in some places the sugar-cane is cultivated to a small extent. In the hill country the season of harvest is later than in the plains of the Jordan and of the sea-coast. In the plain of the Jordan, the wheat harvest is early in May; in the plains of the coast and of Esdraelon, it is towards the latter end of that month; and in the hills, not until June. The barley harvest is about a fortnight earlier than that of wheat.

Animals. Palestine in ancient times was distinguished for the abundance of its cattle, including sheep, goats, camels, and asses; and these, though now much diminished in numbers, still constitute a principal part of the wealth of the inhabitants. Herds of black cattle are now rarely to be seen, though they would seem to have been common in ancient times. This no doubt arises from the heavy and unscrupulous exactions of the government, from whose notice wealth, in the shape of animals so large, could not easily be concealed or withdrawn. The ox in the neighbourhood of Jerusalem is small and unsightly, but on the Upper Jordan, especially to the east of that river, and in the vicinity of Tabor and Nazareth, it thrives better and is more common. The bulls of Bashan are frequently alluded to in Scripture as being particularly strong and ferocious. The buffalo is met with in various parts,—on the coast it is equal in size and strength to those of Egypt. Sheep and goats are still to be seen in great numbers in all parts of the country. Their flesh and milk serve for daily food, and their wool and hair for clothing. Mutton is, and always has been, the principal animal food used in the East; beef or veal is now but rarely eaten, though it seems to have been made use of by the ancient Israelites to a considerable extent. The sheep of Palestine are all of that species which is characterized by an enormously large tail, chiefly composed of fat. They are horned, and commonly white,—black ones are very rare. There are two species or varieties of the goat; one differing little from the common species, the other considerably larger in size, with long, hanging ears, and in the head and horns very much resembling a ram. The latter is furnished with hair of considerable fineness, but seemingly not so fine as that of the same species in Asia Minor. The "wild goats" mentioned in Scripture were probably the ibex and the kebsch, both of which are still found in the mountains of Palestine. The latter is also called the wild sheep, though it bears little resemblance to that animal, and is chiefly distinguished by a long pendant mane about its throat and the upper part of its fore-legs. The milk of goats was by the Jews more esteemed than that of any other animal, and the flesh was in high favour, especially that of kids. Camels are still, as they were in Scripture times, the principal beasts of burden in Palestine, the roads being few and not suited for carts or carriages.[1] It is an animal that is invaluable to the wandering Arab tribes, and is used both for carrying burdens and for riding. The flesh was forbidden to the ancient Jews, but is eaten by the Arabs, and the milk is much used. The horse was not much made use of by the ancient Israelites, and the rearing of it was discouraged by law. It was chiefly employed in warlike enterprises and for state purposes. The horses of Egypt are the earliest mentioned, and that country was always famous for them. The horse at present is not a common animal in Palestine, although some fine animals of the high Arabian breed are not unfrequently seen. The ass was more commonly used by the Jews than the horse, and frequently persons of the first consequence rode on it. It was also employed to carry burdens and in labours of the field, but was prohibited from ploughing in the same field with the ox. The ass in the East, when properly trained and cared for, is an active and docile animal; and hence the term is used in Scripture in a laudatory sense. Wild asses are often named in Scripture, but they are not now to be found in Palestine, though they are still to be seen in Mesopotamia and farther east. They are of an elegant figure, and of great swiftness, roaming in herds in desert places far from the abodes of men. Mules are first mentioned in the time of David, but were probably known much earlier. They do not seem to have become very common. Asses and mules are at present much used for riding, as they afford a means of locomotion well suited to the difficult mountain paths of the country.

Among the wild animals, the lion, though not uncommon in ancient times, seems to be now extinct in the country. Bears, however, are still to be met with among the mountains. Boars are often observed upon Mount Tabor and the woody slopes of Mount Carmel, and from thence they

[1] "Roads for wheeled vehicles are now unknown in any part of Palestine; and in the earlier history they are very rarely mentioned. As a general means of communication, the 'chariots' of Jehu and of Ahab are only described as driven along the plain of Esdraelon. Under the Romans, indeed, the same astonishing genius for road-making which carried the Via Flaminia through the Apennines, and has left traces of itself in the narrow passes of the Scironian rocks, may have increased the facilities of communication in Palestine; and hence, perhaps, the mention of the chariot road through the pass from Jerusalem to Gaza, where the Ethiopian met Philip. But under ordinary circumstances, they must have always been more or less impracticable in the mountain ranges." (Stanley.)

Palestine. frequently descend into the plains of Acre and Esdraelon. Jackals are common, and are very destructive to the flocks. The hyæna is found chiefly in the valley of the Jordan, and in the mountains around the Lake of Tiberias, but it is also occasionally seen in other districts of Palestine. The panther is found among the mountains of Central Palestine. Wolves and foxes are common. The gazelle or antelope is often seen in flocks bounding over the grassy plains, and is hunted by the Arabs. Among the rest may be mentioned porcupines, hedgehogs, hares, conies, jerboas hares, rats, mice, and moles. The conies, "a feeble folk" who "make their houses in the rocks," have been identified with the *wubar*, an animal characterized by the liveliness of its motions and the quickness of its retreat within the rocks when danger is apprehended. Except in the head, it very much resembles a rabbit, but is of a stronger build and of duskier colour, being of a dark brown. "It is entirely destitute of a tail, and has some bristles at its mouth, over its head, and down its back, along the course of which there are traces of light and dark shade. In its short ears, small, black, and naked feet, and pointed snout, it resembles the hedgehog." (Wilson.)

The birds of Palestine are not numerous. "In no region," says Dr Wilson, "in which we had before travelled had we seen so few of the feathered race as in the Holy Land." The number of distinct species, however, is considerable. Among the more important or better known may be noticed,—the vulture, eagle, osprey, roller, ostrich, kite, hawk, crow, owl, golden oriole, cuckoo, bee-eater, kingfisher, woodpecker, woodcock, partridge, spoonbill, stork, heron, pelican, swan, goose, duck, and quail. The katta, a bird much more common than this last, and about the size of a partridge, is supposed to be the quail of Scripture. There are no serpents of large size, and it seems to be doubtful if there be any of a venomous nature found in Palestine. Scorpions hold a principal place among the noxious animals; and mosquitoes are common. Bees are extremely common in this "land of honey," and deposit their honey in trees and crevices of the rocks. Occasionally the country is visited by immense swarms of locusts, which consume grass, foliage, and every species of vegetation. Beetles are abundant, and of various species; and mosquitoes are rather common.

The principal towns of Palestine will be found noticed under their respective names in other parts of this work; and an account of the present inhabitants will be given under SYRIA, of which country Palestine is now only a division.

Divisions. The earliest inhabitants of Palestine were known by the general name of Canaanites, being descended from Canaan, the youngest son of Ham. By them the country was thinly peopled in the time of Abraham; and they were divided into several distinct nations. These nations were,—the Kenites, the Kenizzites, the Kadmonites, and the Gergashites, who dwelt to the E. of the Jordan and the Lake of Gennesareth; the Hittites, the Perizzites, the Jebusites, and the Amorites, who occupied the hilly region in the S.; the Canaanites, properly so called, who dwelt in the middle of the country; and the Hivites, who inhabited the extreme N., among the southern branches of Lebanon; while the Phœnicians occupied the northern, and the Philistines the southern part of the coast. In the time of Moses the nations W. of the Jordan seem to have occupied the same positions as before; but the eastern region was divided into three large territories,—Bashan in the N., Gilead in the centre, and in the S. the land called the Plains of Moab, a part of the territory of the Moabites which had been conquered from them by the Amorites. After the conquest of Palestine by the Israelites under Joshua, the country was divided among the twelve tribes, by whose names the various portions were subsequently known,—Judah, Benjamin, Simeon, and Dan inhabiting the southern portion; Ephraim, the half tribe of Manasseh, and Issachar, the central; Zebulon, Naphtali, and Asher, the northern; and Reuben, Gad, and the remaining half of Manasseh, the country E. of the Jordan. Palestine was afterwards divided into the two kingdoms of Israel and Judah; the latter including the tribes of Judah and Benjamin, and the former the other ten. In the time of our Saviour, Palestine was divided into the following provinces:—Galilee, in the N., consisting of Upper or Northern, and Lower or Southern Galilee; Samaria in the centre; and Judea in the S. of Palestine proper; while, on the E. of the Jordan, Peræa was subdivided into eight smaller districts.

History. The earliest event in connection with Palestine recorded in sacred history is the arrival in the country of Abraham, who, along with Lot, his nephew, migrated hither at the Divine command from Mesopotamia in the year 1921 B C. The following year a famine in Canaan compelled Abraham to remove into Egypt, but he soon after returned; and finding the pastures insufficient for the large flocks and herds of himself and Lot, he separated from his nephew, who settled in Sodom, while Abraham himself took up his abode in the valley of Mamre, near Hebron. Previous to the arrival of Abraham in Canaan, Chedorlaomer, who is called in the Bible, King of Elam or Elymais, a part of Persia, and who is said by Josephus to have been a vassal of the Assyrian empire, extended his conquests beyond the Euphrates, and reduced into subjection five of the petty kings or chiefs who lived in the valley S. of the Dead Sea. After twelve years of submission, and about eight years after the coming of Abraham, these five chieftains rebelled against Chedorlaomer, who in the next year (1912 B C.) invaded the country with three other monarchs, and after defeating the rebels in a pitched battle, retired, carrying with him from Sodom and Gomorrah large quantities of booty and many captives, among whom was Lot. Abraham, hearing of this disaster, armed all his followers, to the number of 318, and pursued the retreating army. He overtook them near the source of the Jordan, fell upon them by night, and totally defeated them, rescuing his nephew and the rest of the captives along with their goods.

The destruction of Sodom and Gomorrah took place in the year 1897 B C., when, on account of the wickedness of these cities, God rained brimstone and fire from heaven upon them, by which they were entirely destroyed. The only persons who escaped from this catastrophe were Lot and his two daughters After Abraham's death, Isaac became the head of the patriarchal family, and he seems to have resided all his life in the Promised Land. The only event of historical importance that is recorded in his days is the covenant he made with Abimelech, King of the Philistines, a successor of the monarch of the same name with whom his father had entered into a similar alliance. In 1759 B.C., Jacob, Isaac's younger son, obliged to leave the country on account of the resentment of his brother Esau, took refuge in Mesopotamia with his uncle Laban. There he remained for twenty years in the capacity of servant, receiving in marriage Laban's two daughters, Leah and Rachel, as the price of the first fourteen years, and large flocks of sheep and goats, which constituted the principal riches of those days, for the remaining period of his service. At last, in the year 1739 B C., Jacob returned to Canaan with his wives, the eleven sons that had been born to him in his exile, and his flocks. On his way to that country, Jacob was reconciled to his brother Esau, who had established himself as a powerful prince in the mountains of Seir, the country afterwards occupied by the Edomites, his descendants. In 1728 B C., Joseph, the favourite son of Jacob, was by his brethren sold to a company of Ishmaelites and Midianites, and carried down to Egypt, where he was re-sold to Potiphar, one of the chief officers of the king. On account of a false accusation by his mistress, he was thrown into prison, where he remained for some time. Having, however, interpreted two dreams of the king, and thereby foretold seven years of plenty and seven years of famine, he was raised by the king to the highest authority. During the seven plentiful years he stored up the corn in granaries, so that when the famine came there was still corn in Egypt. Jacob sent down his sons to Egypt for corn, but they knew not their brother Joseph. On their second visit, he made himself known to them, and invited Jacob his father, and all his household, to come into Egypt. This invitation was complied with; and in 1706 B C. the whole patriarchal family, to the number of 76, removed to Egypt, and settled in the land of Goshen. The people while in Egypt rapidly increased in numbers, and continued unmolested until the rise of a new dynasty in that country. The monarch, alarmed at the rapid growth of an alien people in his dominions, took measures to prevent, if possible, their increase, by

reducing them to the condition of slaves, and destroying all their male children. A deliverer was, however, at length raised up for the people in the person of Moses, who, when he could be no longer concealed by his mother, was committed to the river in a basket of bulrushes, and being discovered by the king's daughter, was adopted by her, and brought up at the Egyptian court. But in the year 1531 B.C. Moses, then forty years old, espoused the cause of his oppressed countrymen, and was compelled to leave Egypt. He took refuge among the Midianites, near the eastern arm of the Red Sea, and remained there as a shepherd for 40 years. At the end of that time, he, along with his brother Aaron, was divinely commissioned to deliver the Israelites out of Egypt. This deliverance was effected in the year 1491 B.C. by means of the ten plagues with which the Egyptians were afflicted, and which compelled them at last to let the Israelites go.

When they took their departure from Egypt, Moses was their ruler and their guide. He led them through the wilderness, where they were fed by the miraculous interposition of heaven; and through him their Divine Legislator gave them laws and statutes. But the burden of his office being too great for him, the judicial duties were divided; all lesser causes being, by the advice of his father-in-law, referred to the rulers of thousands, of hundreds, of fifties, and of tens, while those only of greater moment were submitted to the chief judge. Moses was succeeded in his office by Joshua, under whom the Israelites obtained possession of the land of Canaan, which was partitioned by lot among the different tribes, and again subdivided among the families of the same tribe. The land was declared inalienable, and the perpetual inheritance of the families to whom it was originally assigned; and accordingly, every fiftieth year, which was proclaimed to be a year of jubilee, all debts and mortgages on land were declared to be cancelled, and every man was to return into his own land. Other laws were passed for enforcing the purity of divine worship and of moral conduct; for equity in the transactions between man and man; and also for the punishment of idolatry and other iniquities; for it was the peculiar distinction of this community, that the law took cognisance not only of offences against society, but of every breach of the Divine commands. The order of the priesthood was also instituted in the family of Levi, gifts and sacrifices were offered by them in expiation of sin, and various acts were enumerated by which the children of Israel became unclean, and which, though innocent in themselves, were yet employed to point out the great defilement of sin, and for which, therefore, certain modes of purification were appointed. The distinction was also laid down between clean and unclean animals, from the latter of which the people were commanded to abstain. An enumeration was made in the plains of Moab of all the males of the children of Israel above twenty years of age, and the sum of them is given at 601,730; the Levites, who were not mentioned among the rest, amounted to 23,000; which makes the sum of 624,700 males above twenty years of age. The total population must therefore at that time have been about 2,500,000. The Israelites, after their settlement in the land of Canaan, were involved in wars with the surrounding states, and were often given into their hands on account of disobedience. The land was in this manner frequently wasted, and the happiness of the people interrupted, by the inroads of their neighbours. From these enemies they were saved by deliverers called judges, raised up to them, under whose peaceful sway the land enjoyed long intervals of rest. But during the old age of Samuel, the last of the judges, in consequence of the misconduct of his sons and the unsettled state of the country, the people were dissatisfied, and entreated, against the solemn protest of this aged prophet, that they might have a king, like the nations around them; and Samuel was desired to hearken to their request. Saul was accordingly (1095) chosen king; but, on account of his disobedience, the kingdom was rent from him, and given to David; and he terminated his fatal course in a disastrous defeat on the mountains of Gilboa, in which he and his son Jonathan were slain. David ascended the throne of Judah in 1055, but Ishbosheth, a son of Saul, reigned for seven years over the other tribes. The latter being murdered in 1048, David became king of the whole country without dispute, and commenced a prosperous reign, in the course of which he subdued all his enemies. Although the peace of the country was disturbed by the domestic treason of Absalom, yet David left a flourishing kingdom to his successor Solomon, under whose reign (1015–975) the kingdom was enlarged on every side, and became one of the most flourishing empires of Asia, extending on the east as far as the Euphrates, and possessing ports both on the Mediterranean and on the Red Sea. David was a man of war, but Solomon was devoted to peace; and accordingly, during his reign was constructed that magnificent temple at Jerusalem which was the wonder of future ages.

After the death of Solomon, the kingdom was divided into two sovereignties. The tyrannical conduct of Rehoboam, in which he persisted, against the advice of his aged councillors, gave rise to the revolt of the ten tribes, who chose Jeroboam for their king; and thus began that division of the empire which paved the way for its downfall under the successive attacks of its enemies. The kingdoms of Israel and Judah were hereafter ruled by different monarchs, who no longer joined against their common enemies, but waged war against each other; and, in place of the union that might have been expected in the descendants from a common stock, they regarded each other with all the aversion of aliens. In the meantime, the powerful empires of Assyria and Babylon in the E., and of Egypt in the S., were contending with each other for the dominion of the world; their vast armies frequently threatened the destruction of the comparatively petty states of Judea; and at length, in the reign of Hoshea, 721 years before the Christian era, Samaria, the capital of the kingdom of Israel, was taken by the King of Assyria, the land conquered, and the whole nation carried into captivity.

We subjoin a list of the kings who reigned in Samaria, with the length of their several reigns, and the period when they reigned:—

		B.C.			B.C.
1. Jeroboam I.	21 yrs.	975	13. Jeroboam II.	41 yrs.	823
2. Nabab	14 „	954	1st *Interregnum*	11 „	782
3. Baasha	23 „	953	14. Zachariah	6 mos.	771
4. Elah	1 „	930	15. Shallum	1 „	771
5. Zimri	7 days	929	16 Menahem.	10 yrs.	770
6. Omri	11 yrs.	929	17. Pekahiah	2 „	760
7. Ahab	21 „	918	18. Pekah	20 „	758
8. Ahaziah	1 „	897	2d *Interregnum*	10 „	738
9. Jehoram	12 „	896	19. Hoshea	7 „	728
10. Jehu.	28 „	884			
11. Jehoahaz	17 „	856	Samaria taken	254 „	721
12. Jehoash	16 „	839			

The kingdom of Judah, weakened by the loss of the ten tribes, was afterwards assailed by the King of Babylon; and was at length brought to an end by Nebuchadnezzar in 588 B.C. Jerusalem was taken and destroyed along with the temple, and the king, the princes, and most of the people of Judah were carried away to Babylon.

The following is the line of kings who reigned in Jerusalem from the death of Solomon to the destruction of the first temple:—

		B.C.			B.C.
1. Rehoboam	17 yrs.	975	13. Hezekiah	27 yrs	725
2. Abijah	3 „	958	14. Manasseh.	55 „	698
3. Asa.	41 „	955	15. Amon	2 „	643
4. Jehoshaphat	25 „	914	16. Josiah	31 „	641
5. Jehoram or Joram	4 „	889	17. Jehoahaz	3 mos.	
6. Ahaziah	1 „	885	18. Jehoiakim	11 yrs.	610
7. Queen Athaliah	6 „	884	19. Coniah or Jehoiachin	3 mos.	
8. Joash or Jehoash	40 „	878	20. Zedekiah	11 yrs.	598
9. Amaziah	29 „	838			
10. Uzziah or Azariah	52 „	809	Jerusalem taken	387 „	588
11. Jotham	16 „	757			
12. Ahaz	16 „	741			

Seventy years were appointed as the term of the Jewish captivity, in the course of which the empire of Babylon was overthrown by Cyrus the king of Persia, in whose reign the Jews were encouraged to rebuild their city, and to return to their own land. Zerubbabel, Ezra, and Nehemiah, were the successive leaders that presided over the restoration of the Jewish kingdom. After many interruptions from the jealousy of their powerful enemies, the second temple was at length reared. But it was so inferior in magnificence and splendour to that of Solomon, that the aged men wept when they contrasted this modern structure with the glory of the first house. The Jews were now ruled by the Persian king and his lieutenants in civil though not in sacred things, which were regulated by the law of Moses as administered by their own high priests; and they enjoyed for a period of nearly two centuries the blessings of a settled government. After the conquest of Persia by Alexander, and the division of his kingdom among his successors, Asia was distracted by new wars among those rivals for the supreme dominion, and the Jews often embarrassed by these contentions, owed their independence rather to the forbearance of their enemies than to their own strength. At length, however, Antiochus Epiphanes, who ascended the throne of Syria in 175 B.C., having heard of insurrections among them, invaded their territory with a powerful army, and besieged and took Jerusalem while it was yet unprepared for defence. He wreaked his vengeance on the unhappy Jews, 4000 of whom were put to death, and an equal number reduced to slavery. The temple was plundered of all its treasures and sacred utensils, and an unclean animal, a sow, was offered by his orders on the altar of burnt-offerings. The Jewish nation was at the same time cruelly persecuted; an edict was issued for the extermination of the whole race; and in furtherance of this barbarous policy, Apollonius, the commander of the troops, when the people had assembled in Jerusalem on the Sabbath, made a furious

attack with his troops on the peaceful multitude, whom he slaughtered without mercy, or carried into a hopeless captivity. The city was plundered, and set on fire in many places; the walls were broken down, and a strong fortress built on Mount Zion, which commanded the temple and the adjacent parts. Having made these preparations, he proceeded to farther persecutions against the religion of the Jews. They were watched in their visits to the holy sanctuary, and harassed by the troops; the rite of circumcision was prohibited; and a compliance with the heathen idolatries was enforced at the point of the sword. They were compelled to profane the Sabbath and to eat swine's flesh. The holy temple was violated by the worship of Jupiter, whose statue was erected on the altar of burnt-offerings, and the licentious revels of the Bacchanalia were substituted for the pure festivals of the Jewish church. The rage of persecution spared neither age nor sex; and all over the country torture and death were inflicted on the unhappy persons who, remaining stedfast in their faith, refused to participate in these heathenish rites.

Such unheard-of cruelties excited the deepest indignation, and at length roused the nation to resistance. The heroic family of the Maccabees, consisting of five brethren, the sons of Mattathias, a priest of the race of Asmoneus, were the champions of the patriotic cause. They were all of renowned valour; and Judas having headed the insurgents, a determined band only 6000 in number, defeated the oppressors of his country in many great battles, and restored its independence (165 B C.) But he had to contend against domestic treason as well as foreign war. Alcimus, who was in the interest of the Syrians, assuming the title of high priest, claimed the allegiance of the Jews, and Judas was compelled in self-defence to seek the alliance of the Romans, who eagerly sought a pretence for interference in the affairs of their neighbours. In the meantime, the Maccabee chief was slain in the field of battle (161 B.C.), and was succeeded by his brother Jonathan, who, employing his power in aiding Alexander Balas to obtain the crown of Syria, was allowed by him in return to unite the spiritual authority of the high priest with the temporal sway (153 B.C.); and under this dynasty of the Asmonean princes Palestine was governed for more than a hundred years. Jonathan was succeeded by his son Simon (143 B C.), who secured the tranquillity of the country by cultivating the friendship of Rome. He was cut off, the victim of domestic treason; and John Hyrcanus, his younger son, ascended the throne (136 B.C.) His reign was prosperous and successful. He not only threw off the Syrian yoke, but extended his territories eastward and northward. He besieged and utterly destroyed Samaria; and thus gratified the vindictive spirit of the Jews against the Samaritans. The short reign of Aristobulus, his son, followed in 106 B.C.; in the next year that of Alexander Jannæus, whose oppressions excited a civil war in the country. The insurgents, calling in the aid of the Syrians, became unpopular; and Alexander, after many reverses, at last succeeded in collecting a powerful army, with which he completely re-established his power, and took vengeance on his enemies. He was succeeded in 78 B.C. by his son Hyrcanus the Second. His brother Aristobulus, after secretly opposing him for some time, at length threw off the mask, and openly aspired to the supreme power. The two competitors were preparing to appeal to arms, when the Romans under Pompey, having subdued the greater part of Syria, were now called into Palestine as peaceful arbiters in this dispute. Aristobulus, however, being impatient, had recourse to arms, and shut himself up in Jerusalem, which was invested in the year 63 B.C. by the Roman general Gabinius, the lieutenant of Pompey, and carried by assault with great slaughter. The authority of Hyrcanus was reestablished, and Aristobulus was carried prisoner to Rome, whence afterwards making his escape, he raised the standard of revolt in Judea. But he had no force that could oppose the Roman armies under Mark Antony, who speedily re-established the authority of Rome in every part of the country. The rule of Judea was in 47 B.C. delegated to Antipater, the minister of Hyrcanus, who appointed his two sons, Phasael and Herod, to be governors, the one of Jerusalem, and the other of Galilee. But a new competitor appeared for the supreme authority in Judea, namely, a son of Aristobulus, who, having taken refuge among the Parthians, invaded the country with a powerful army, and succeeded in obtaining the kingdom. Phasael committed suicide, and Hyrcanus was deprived of his ears and sent to Babylonia; but Herod, the younger son of Antipater, escaped to Rome, where, through the influence of Antony, he was made king of Judea (B.C. 40). Two years afterwards he established himself on the throne, and thus put an end to the Asmonean dynasty. He employed himself in works of architecture, particularly in the repair of the temple, by which he hoped to obtain favour among the Jews. It was in his reign that the Messiah was born, and it was from his cruelty that he fled into Egypt. On his death, in the year 4 A.D., he bequeathed his dominions to his three sons: to Archelaus the government of Idumea, Samaria, and Judea; to Antipas that of Peræa and Galilee; and to Philip that of Trachonitis, Gaulanitis, Batanea, and Paneas, lying partly beyond the limits of Palestine. Archelaus was soon after deprived of his great office, on account of maladministration, and banished into Gaul. Judea was now reduced to the condition of a Roman province, under a governor who resided at Cæsarea, but who was subordinate to the prefect of Syria. One of these governors was Pontius Pilate, under whose authority the Saviour was crucified. The Jews were far from being a contented or happy people under the Roman yoke. They were exposed to the severe exactions of their delegated rulers, and to outrages and plunder by the Roman soldiers stationed in the province to overawe the people. Disturbances, provoked by these oppressions, and quelled by the legionary troops, became the pretext for fresh cruelties; and misery, disorder, and violence thus reigned throughout the once happy land. The only portion of the country that enjoyed comparative quiet was Galilee and the country beyond Jordan, which was ruled by Antipas and Philip. In 38 A.D. Herod Agrippa was appointed, by Caligula, king of Galilee and the country beyond Jordan; and in 41 B C. he obtained from Claudius the rest of the dominions of his grandfather, Herod the Great. His policy was conciliatory towards the Jews; he respected their worship, repaired and adorned the temple, and joined with them in their persecution of the new sect of Christians, having put to death the apostle James. His miserable end, being eaten of worms, is related in the Acts of the Apostles. His son Agrippa succeeded him, but after his death Judea was again governed by Roman procurators. The discontent of the Jews, their impatience of the Roman yoke, their proneness to insurrection under the vain predictions of their soothsayers, that a conquering Messiah was to arise, who should restore the independence and glory of their country, afforded too fair a pretence for the severities of their rulers. The country abounded in scenes of rapine and anarchy; the national faith and the holiest rites were despised and trampled upon; and at length, under the administration of Florus, the people flew to arms, and entered on their last and desperate conflict with the Roman power. The insurrection broke out (in the year 65 A.D.) at Cæsarea, the inhabitants of which, galled by cruel insults, declared their determination to resist to the last extremity. The Jews in Jerusalem shared in this heroic determination, and made preparations for defence. Cestus, the prefect of Syria, advanced to the gates and demanded an entrance for the Roman troops. The Romans were, however, on this occasion defeated with great slaughter, and lost all their artillery.

The intelligence of these disasters excited the indignation of Nero, who sent Vespasian, a man of tried valour and experience, to assume the government of Syria, and to calm the troubles of that distracted province. He entered Judea about the year 67, along with his son, the renowned Titus, to whom was committed the conduct of the war. Many sanguinary battles were now fought between the contending armies, in which the tumultuary levies of the Jews were broken and dispersed by the veteran legions of Rome; towns and fortresses were successively taken; and the Jews, no longer able to face the enemy in the field, were driven within the walls of their capital, to which Titus at length laid siege. The defence was obstinate, and the besiegers were brave and numerous, employing all the resources of the military art in their attack on the devoted city. In the course of this protracted siege partial successes were obtained by the Jews, who fought bravely, and harassed the besiegers by frequent and successful sallies. But the defences of the city, strong both by nature and art, gradually gave way before the perseverance and skill of the Roman troops; and as Titus proceeded partly by blockade, he shut in the whole city with a wall, and the horrors of famine were added to all the other miseries which the inhabitants suffered. It would be endless to detail all the horrors of this protracted siege; famine raged within the walls; every inch of ground was fiercely disputed; and prodigious numbers of men fell on both sides. But the Romans made a steady progress. The city was not completely in their hands till four months after the beginning of the siege; and notwithstanding the wishes of Titus to save it, the temple was consumed by fire. The inhabitants were everywhere put to the sword, or made captives and sold for slaves. The number of Jews who perished in the siege is estimated at 1,100,000, a far greater population than the city usually contained; but the annual feast of unleavened bread, which took place at this time, had crowded it with a vast concourse of strangers from all quarters, who, by the sudden approach of the hostile army, were shut up within the walls. The destruction of the city took place in the year 70 A.D.

After the Roman armies were withdrawn from Jerusalem, many of the Jews returned to dwell in the ruined city, though the Roman emperor, indignant at the late rebellion, had placed a garrison of 800 troops on Mount Zion, in order to prevent any attempt to rebuild the sacred capital. The Jews, however, were still discon-

tented and rebellious; they still fondly believed that an earthly Messiah was shortly to arise, to free them from bondage, and to give them the dominion of the whole earth They accordingly listened to the tales of every impostor, and were easily seduced into rebellion by vain hopes of national glory that were never realized. In the course of these commotions great cruelties were committed; but in the end the Jews were everywhere borne down by the discipline of the Roman legions, and paid the penalty of their rebellion with their lives. By acts of mutual cruelty the animosity of both parties was inflamed; the sword of persecution was let loose against the Jewish religion by their conquerors; the rite of circumcision, the reading of the law, and the observance of the Jewish Sabbath, and all the other memorials of the national faith, were forbidden. In the city of Jerusalem, which was to a certain extent repaired, a colony of Greeks and Latins was established, in order to preclude the return of the Jews, and all further hopes of the restoration of their kingdom. But the policy of the Romans was of no avail against the deep-rooted prejudices of this infatuated people; and no sooner had a new impostor arisen in 131, of the name of Barcochab, "the son of a star," than the deluded Israelites hailed him as the light that was to dawn in the latter days, and usher in the day of their long-expected rest. They accordingly crowded to his standard; and in a short time he had mustered a powerful army of 200,000 devoted followers. Owing to the absence of the Roman legions, engaged at that time in distant service, important advantages were gained, and Jerusalem was again occupied by the insurgent Jews, besides about fifty castles, and numbers of open towns. But this career of success was speedily terminated by the arrival of Severus, afterwards emperor, with a large and well-appointed body of legionary troops; the Jews were overwhelmed by numbers, discipline, and military skill; their cities were taken and destroyed; and Bither, where the leader of the rebellion, Barcochab, had made his last stand, was stormed with great slaughter, and himself slain. Of the Jews it is estimated that 580,000 died on the field; and the remnant who escaped mostly perished by famine and disease, or amid the flames of their ruined cities. Under these ruthless devastations the country was at last converted into a desert; the inhabitants were either slain or driven into exile; and the Divine denunciations were now literally fulfilled against this misguided people, that they should be scattered among all the nations of the earth.

The victors having thus satiated their vengeance, began in due time to relax their stern and intolerant policy. Under the mild rule of Antoninus Pius, the Jews were restored to their ancient privileges, to the freedom of worship, and to all their other national rites. They were now mingled with the nations, and were found dwelling in all parts of the Roman empire; and their general condition at this time, as described by Gibbon, was not unfavourable. "The numerous remains," says this eloquent historian, "of that people, though they were excluded from the precincts of Jerusalem, were permitted to form and to maintain considerable establishments both in Italy and in the provinces, to acquire the freedom of Rome, to enjoy municipal honours, and to obtain at the same time an exemption from the burdensome and expensive offices of society. The moderation or contempt of the Romans gave a legal sanction to the form of ecclesiastical police which was instituted by the vanquished sect. The patriarch, who had fixed his residence at Tiberias, was empowered to appoint his subordinate ministers and apostles to exercise a domestic jurisdiction, and to receive from his dispersed brethren an annual contribution. New synagogues were frequently erected in the principal cities of the empire; and the sabbaths, the fasts, and the festivals, which were either commanded by the Mosaic law, or enjoined by the traditions of the rabbis, were celebrated in the most solemn and public manner. Such gentle treatment insensibly assuaged the stern temper of the Jews. Awakened from their dream of prophecy and conquest, they assumed the behaviour of peaceable and industrious subjects. Their irreconciled hatred of mankind, instead of flowing out in acts of blood and violence, evaporated in less dangerous gratifications. They embraced every opportunity of overreaching the idolaters in trade; and they pronounced secret and ambiguous imprecations against the haughty kingdom of Edom." (*Decline and Fall*, vol. ii., chap. xvi.) This statement, though it has received a colouring from the deep-rooted prejudices of the author against the Jewish religion, is nevertheless substantially true, and contains a just view of the condition of the Jews throughout the Roman empire. No great change appears to have taken place in the condition of Palestine until Constantine ascended the imperial throne in the year 306. He was, as is well known, the first Christian emperor; and under his powerful patronage, and that of his mother the Empress Helena, splendid structures were everywhere erected in the Holy Land in honour of the Christian faith. The land was gradually overspread with memorials of Christianity; and chapels, altars, and houses of prayer marked every spot said to be memorable for any of the sayings or doings of the Saviour. The Jews beheld with indignation the rise of these Christian monuments within the precincts of the holy city, since they were as much opposed to the Christian worship as to the heathen idolatry. But [illegible] was now at an end. Scattered in distant parts, they could no longer act with consistency or vigour; yet so attached were they to their own ancient rites, that, however faint the chance of success, they were ready in crowds to rally round the standard of their ancient faith wherever it was displayed, and to follow any daring leader into the field. But the time was past. Jerusalem was now filled with the emblems of a new faith, and crowds of pilgrims were attracted from the most distant countries by the eager desire of contemplating the place of the Redeemer's passion, and of the previous incidents of his life. These visits were encouraged from various motives. They evinced, no doubt, the zeal of the new converts; and being at once a proof of piety and a source of profit, they were encouraged by the clergy of Jerusalem.

The reign of Julian (361-363) was a new era in the history of Palestine; and the Jews anticipated, from his declared enmity to Christianity, his favour for their own faith. The policy of this heathen emperor countenanced them in this belief, when he endeavoured, by rebuilding the temple of Jerusalem in its former splendour, to discredit the truth of those prophecies which denounced perpetual desolation on the devoted city. He chose the commanding eminence of Mount Moriah for the site of a new structure, which was to eclipse the splendour of the Christian church on the adjacent hill of Calvary; and he resolved to establish a Jewish order of priests, who might revive the observance of the Mosaic rites, together with as numerous a colony of Jews as could be collected, in the holy city. Such was still the ardour of the national faith that the Jews crowded from all parts, and exasperated by their insolent triumph the hostility of the Christian inhabitants. All now joined with unwearied zeal in the sacred work of rebuilding the temple. Liberal contributions poured in from all quarters; men and women joined in the labour; and the authority of the monarch was seconded by the enthusiasm of the people. But this last effort of expiring zeal was unsuccessful; no temple ever arose on the ruins of the heathen edifices; and the progress of the work, according to a story generally believed at the time, was stopped by the interposition of heaven, by flames of fire bursting out from the foundations with loud explosions, by which the workmen were so terrified that they refused to continue their labour. The attempt, from whatever cause, was abandoned; and as it was only undertaken during the last six months of Julian's reign, the fact seems sufficiently explained, without the aid of a miracle, by the absence and death of the emperor, and by the new maxims that were adopted during the Christian reign that succeeded.

After the death of Julian it was the policy of the Christian emperors to depress the Jews in Palestine, though they were not ill treated throughout the provinces, and were even granted considerable privileges and immunities. But it is astonishing how carefully the fathers instilled into the minds of their children, along with their ancient faith, the fondly-cherished delusion, that some new and happier era of freedom and independence was yet to dawn on Judea; and how eagerly the children, imbibing this idea, became the prey of every impostor, and, under the blind impulse of enthusiasm, rashly entered into new conflicts with their enemies in the field, where they perished, the willing victims of a hopeless cause. About the beginning of the seventh century the peace of Judea was seriously disturbed by the Persian invasion of Chosroes. The Greeks and the Persians were for a long period rivals for the dominion of the East; and Chosroes, the grandson of Nushirvan, now invading the Roman empire, successively stormed and sacked the cities of Antioch and Cæsarea in Cappadocia. From Syria the flood of invasion rolled southward on Palestine, and the Persian army was joined by the Jews to the number of 26,000, still burning with the love of independence. Jerusalem was stormed by the combined armies in 614, the city was sacked, and the magnificent monuments of the Christian faith were mostly consumed by fire. But this, like all the other triumphs of the Jews, was short-lived. Heraclius, roused from inglorious sloth by the triumphs of the Persian arms, and by the approach of the victorious force to the walls of his own capital, quickly assembled his veteran armies, by whose aid he defeated the troops of Chosroes in 622; and in the course of a few successful campaigns he recovered all the provinces that had been overrun. He visited Jerusalem after his victories, in the lowly guise of a pilgrim, and prepared new triumphs for the Christians in the restoration of the magnificent churches which had been destroyed, in the persecution of the Jews, and in their banishment, as before, from the Holy City, which they were now forbidden to approach within a distance of 3 miles.

Palestine continued to own the sway of the Greek emperor till the rise of the Saracen power in the East. The followers of Mo-

hammed, extending their doctrines and their dominion by fire and sword, rapidly subdued Arabia, Syria, and Egypt, and in the year 637 turned their arms against Jerusalem. After a siege of four months, during which the Arabs suffered extremely from the inclemency of the winter, a capitulation was proposed and agreed to, when the Caliph Omar entered the city seated on a red camel, without guards, or any other precaution, and began to discourse in the most courteous manner with the patriarch on its religious antiquities. Omar was assassinated in Jerusalem in the year 643, after which the East was for 200 years distracted by the bloody wars that ensued among the Ommiade, the Abbasside, and the Fatimite caliphs; and Palestine having become an object of contest between them, was for a like period a scene of devastation and trouble. After the division of the Saracen dominions among these three factions in the middle of the eighth century, Palestine remained under the power of the Abbasside caliphs of Bagdad until 969 A.D., when it was transferred to the Fatimite line in Egypt. In 1076 Jerusalem was taken by the Turks, and held by them for twenty years; but in 1096 the Egyptian caliphs regained their power.

Jerusalem, though it was in the possession of infidel chiefs, was still revered as a holy city both by Christian and Jew, and was visited by pilgrims from every quarter; among others, by Peter the Hermit, a native of Amiens. The pathetic tale which he brought to Europe of the injuries and insults which the Christian pilgrims suffered from the infidels who possessed and profaned the Holy City, excited the deepest sympathy among the people and princes of Christendom. Councils were summoned, and were attended by ecclesiastics and laity. The mixed multitude were harangued by the zealous enthusiasts of this sacred cause; their pity and indignation were alternately roused by the sufferings of their brethren in the Holy Land; the flame of enthusiasm was propagated by sympathy and example; and the eager champions of the Cross, the flower of the European chivalry, assembled in martial array to march against the enemies of their common faith. To defray the necessary expenses of the expedition, princes alienated their provinces, the nobles their lands and castles, peasants their cattle and the instruments of husbandry; and vast armies were transported to Palestine, in order to accomplish the deliverance of the Holy Sepulchre. These rude and undisciplined bands died in great numbers on reaching the shores of Asia, from disease, famine, and fatigue; and of the first Crusaders it is estimated that 300,000 had perished before a single city was rescued from the infidels. Of the leaders in the Christian host, the first rank is due to Godfrey, Duke of Brabant and Bouillon, who was accompanied by his two brothers, Eustace the elder, who had succeeded to the county of Boulogne, and Baldwin the younger. The other chiefs were Robert of France, the brother of King Philip, and Robert, Duke of Normandy, the son of William the Conqueror; Bohemond, the son of Robert Guiscard, distinguished by his cool policy and ambition, with a small addition of religious zeal; Tancred, his cousin, who had imbibed the true spirit of chivalry, and all the virtues of a perfect knight; and Raymond of Toulouse, the Duke of Narbonne and Marquis of Provence, a veteran warrior of mature age and experience. The vast armies that were collected under the guidance of these leaders arrived by various routes at Constantinople; and after some time spent in the capital of the East, they crossed to the opposite shore of Asia. Having taken the towns of Nice and Antioch in the year 1097, they laid siege to Jerusalem about two years after, and took it by assault, with a prodigious slaughter of the garrison and inhabitants, that was continued for three days, without respect to age or sex.

Eight days after the capture of Jerusalem, the Latin chiefs proceeded to the election of a king, who should preside over their conquests in Palestine, and Godfrey of Bouillon was unanimously raised to this high position. But if it was an honourable office, it was also one of danger: he was not chosen to sway a peaceful sceptre; and he was summoned to the field in the first fortnight of his reign to defend his capital against the Sultan of Egypt, who approached with a powerful army. His signal victory in the battle of Ascalon confirmed the stability of his throne, and enabled him to extend on every side his kingdom, which consisted then only of Jerusalem and Jaffa, with about twenty villages and towns of the adjacent districts. The fortified castles into which the Mohammedans had taken refuge, and from which they made incursions into the open country, were reduced; the maritime cities of Laodicea, Tripoli, Tyre, and Ascalon, were besieged and taken, and the Christian kingdom thus included a range of sea-coast from Scanderoon to the borders of Egypt. The feudal institutions of Europe were introduced into this kingdom in all their purity; and a code of laws, called the Assize of Jerusalem, was drawn up, which was attested by the seals of the king, the patriarch, and the viscount of Jerusalem, and deposited in the sepulchre of the Saviour, as an unerring guide in all doubtful questions that might be brought before the tribunals of Palestine.

Godfrey was succeeded in 1100 by his brother Baldwin, who ruled with vigour and success. In 1118 his cousin, Baldwin II., ascended the throne, and still maintained the interests of the kingdom. Melisandra, his daughter, married Foulques of Anjou, who in right of his wife acquired the kingdom of Jerusalem. He lost his life by a fall from his horse, after having reigned ten or twelve years. His son, Baldwin III., ruled in Jerusalem twenty years; and his reign was remarkable as the era of the Second Crusade, and of the rise of the various orders of knighthood,—the Hospitallers, Templars, and Cavaliers.

The military force of the first Crusaders, wasted by fatigue and by losses in the field, was no longer able to oppose the hosts of Turks and Saracens by which it was surrounded. The first victories of the Europeans, and their rapid success, extended far and wide the terror of their arms. But this alarm having subsided, the Mohammedan chiefs collected their armies, and commenced a vigorous attack on the European posts scattered over a wide extent of country, and gained some important advantages. The accounts of these disasters that were circulated in Europe excited the liveliest sympathy of all Christians for their suffering brethren in the Holy Land, for the defence of which the European princes now entered into a new coalition. A second crusade was the consequence. It was undertaken in the year 1147, by the Emperor of Germany, Conrad III., and Louis VII., King of France, and was even more unfortunate than the first expedition. In the course of a tedious march through an unhealthy and hostile country, more than half the army of Conrad was wasted by famine and the sword, and not above a tenth part ever reached the Syrian shore. The subsequent battles with the Saracens reduced them to a miserable remnant; and the emperor, on his return with his shattered forces from this unfortunate campaign, was met by Louis and the French troops, who arrived in better condition at the scene of action. The French army, rashly advancing into the heart of the country, was assaulted and overwhelmed by an innumerable host of Turks; and the king, effecting his escape with great difficulty, finally took shipping with his knights and nobles, leaving his plebeian infantry to the sword of the victorious enemy. The two princes afterwards proceeded to Jerusalem, united the poor remains of their once mighty armies to the Latin troops in Syria, and laid a fruitless siege to Damascus, which was the termination of the Second Crusade.

The defeat and dispersion of these armies tended greatly to weaken the Christian cause in the Holy Land, and shake the foundations of the Latin throne at Jerusalem. Disputes also arose about the succession to the throne, which exposed the kingdom still more to the assaults of its enemies, with whom some of the discontented barons entered into traitorous correspondence. In the midst of these internal dissensions the kingdom of the Latins was assailed by a new enemy, namely, the Sultan Saladin, who, to valour, policy, and military skill, joined all the refined humanity of a Christian knight. He had risen from a private station to the sovereignty of Egypt, and had been for years extending his influence and his dominions. Reginald of Chatillon, a soldier of fortune, had seized a fortress, from which he issued with his followers to pillage the caravans and to insult the Mohammedans, and he even threatened the holy cities of Medina and Mecca. Saladin complained of these injuries; and being refused any satisfaction, invaded the Holy Land in 1187 with an army of 80,000 horse and foot. He advanced against Tiberias, to which he laid siege; and a decisive battle was hazarded by the King of Jerusalem in defence of this important place. In the contest which ensued the Christians were totally defeated, their king and many of the nobles taken prisoners, and 30,000 soldiers slain or captured. This great victory placed the whole country at the mercy of the conqueror. The fate of the kingdom had been set on a single cast, and its whole military force concentrated on this fatal field. The towns and castles, deprived of their governors, fell successively before Saladin's victorious force; and scarcely had three months elapsed when he appeared in arms before the gates of Jerusalem.

This city was in no condition to sustain a protracted siege, being crowded with fugitives from every quarter, who here sought an asylum from the destroying sword. A disorderly throng of 100,000 persons were confined within the walls, with but few soldiers. A defence was, however, maintained for fourteen days, after which the capture of the city was averted by a capitulation, by which it was agreed that all the Franks and Latins should quit Jerusalem, receiving a safe conduct to the ports of Syria and Egypt; that the inhabitants should be ransomed for a sum of money; and that those who were unable to pay it should remain slaves. The whole country now submitted to the sultan, whose victorious progress was first arrested by the resistance of Tyre, which was gallantly defended by Conrad. The sultan, being foiled in all his attempts to take this place, was finally compelled to raise the siege, and to retreat to Damascus.

The capture of Jerusalem by the infidels, and the decline of the

Christian cause in Palestine, excited the deepest sorrow; the decaying zeal of the European powers was awakened, and new expeditions were fitted out for the recovery of the Holy City. In the year 1189, Philip, King of France, the Emperor Frederick Barbarossa of Germany, and Richard I of England, assembled a large force; and, with the aid of Flanders, Frise, and Denmark, filled about 200 vessels with their troops. The first armaments landed at Tyre, the only remaining inlet of the Christians into the Holy Land, and no time was lost in commencing the celebrated siege of Acre, which was maintained with an enthusiasm that mocked at danger, and by feats of valour that were the theme of wonder, even in that romantic age. This memorable siege lasted for nearly two years, and was attended with a prodigious loss of men on both sides. At length, in the spring of the second year, the royal fleets of France and England cast anchor in the bay, with powerful reinforcements, and the brave defenders of Acre were forced to capitulate. The place was taken possession of by the Christians on the 12th of July 1191.

The capture of Acre was the prelude to farther operations against the enemy. Richard determined to commence the siege of Ascalon, about 100 miles distant, and his march to this place was a continual battle of eleven days. He was opposed by Saladin with an army of 300,000 combatants; and on this occasion was fought one of the most memorable battles of this or any other age. Saladin was defeated with the loss of 40,000 men, and the victorious Richard obtained possession of Ascalon and the other towns of Judea. In the next year Richard made an unsuccessful attempt against Jerusalem; and a vigorous assault by Saladin on Jaffa was repulsed by Richard. A truce was at length concluded for three years, by which it was stipulated that the Latin Christians should have liberty to visit the Holy City without being liable to tribute; that the fort of Ascalon should be dismantled; and that Jaffa and Tyre, with the intervening territory, should be surrendered to the Europeans. Soon after the conclusion of this treaty Richard embarked for Europe; and Saladin, his great rival, did not survive many months the conclusion of peace. He died at Damascus in the year 1193.

In the meantime, in Palestine, though partial successes were gained by the armies of the Crusaders, their power was on the decline. The Latin kingdom, now reduced to two or three towns, was preserved only in a precarious existence by the divisions and civil wars that prevailed among its enemies.

This intelligence rekindled the dying zeal of the Christian world. A new crusade was commenced; and in 1216 a large force, chiefly of Hungarians and Germans, landed at Acre. The sons of Saphadim, who now ruled in Syria, collected their armies to oppose this formidable attack. But the Crusaders, rashly conducted, and weakened by divisions, advanced into the country without concert or prudence; provisions failed them; they were wasted, as usual, by famine and disease; and at length their leader, the sovereign of Hungary, resolved to quit a country where he had been exposed to hardship and danger, without glory. The crusading armies, thus weakened and discouraged, had laid aside all further idea of offensive operations, when, in the spring of the following year, a fleet of 300 vessels that had sailed from the Rhine appeared on the coast, and brought to their aid powerful reinforcements that recruited their strength, and restored their ascendancy in the field. For reasons that do not clearly appear, they now retired from Palestine, and carried the war into Egypt, where they obtained important successes. They took Damietta by storm, and spread such consternation among the infidels that the most favourable terms of peace were offered, and rejected by them; but having at length wasted their strength on the banks of the Nile, they were reduced to the necessity of bargaining for permission to retire to Palestine, by the cession of all their conquests in Egypt.

The next crusade was undertaken by Frederick II., the grandson of Barbarossa, according to a vow which had been long made, and the performance of which had been so long delayed that he was excommunicated by Gregory IX. By his marriage with Violante, the daughter of John de Brienne, King of Jerusalem, he was the more especially bound to vindicate his right to the kingdom, which he had received as a dowry with his wife. After many delays, he set sail with a fleet of 200 sail and an army of 40,000 men, and in the year 1228 he arrived at Acre. This was the most successful and the most bloodless expedition that had yet been undertaken. Without the hazard of a battle he entered Jerusalem in triumph. The Saracen power was at this time weakened by divisions; and, owing to suspected treachery among his kindred, Kamel, the reigning sultan, held rather a precarious possession of the throne. It was his policy, therefore, rather to disarm the hostility of these powerful armies by treating with them, than to encounter them in the field; and accordingly a treaty was concluded, by which Jerusalem, Jaffa, Bethlehem, Nazareth, and their dependencies, were restored to the Christians; religious toleration was established, and the contending parties of Christians and Mohammedans were allowed each to offer up their devotions, the first at the Holy Sepulchre, and the last in the mosque of Omar. The stipulations of this treaty were not faithfully observed by the Saracens, and the Christians in Palestine still suffered under the oppression of the infidels. New levies were raised in Europe for the Holy War; and a large force of French and English, led by the chief nobility of both nations, landed in Syria in 1239. Numerous battles were fought, which terminated in favour of the Saracens; and the French Crusaders, accordingly, after severe losses, were glad to purchase peace by the cession of almost all their conquests in Palestine. Next year, when the English levy under the Earl of Cornwall arrived at the scene of action, he found, to his surprise, that all the territories and privileges that had been ceded to the Emperor of Germany were lost, and that a few fortresses, and a small strip of territory on the coast, comprised all that the Latins possessed in Palestine. He immediately prepared for the vigorous prosecution of hostilities; but the sultan, being involved in war with his brother in Damascus, readily granted favourable terms as the price of peace—namely, the cession to the Christian armies of Jerusalem, Beritus, Nazareth, Bethlehem, Mount Tabor, and a large tract of the adjoining country. But the kingdom of Jerusalem, thus so happily established, was subverted by a calamity from a new and unexpected quarter. In the interior of Asia the conquests of Ghenghis Khan had brought about the most stupendous revolutions, and the barbarous hordes of the desert, flying before his conquering sword, rushed like a torrent on other nations. The Kharismians, unable to withstand this powerful invader, were driven upon Syria, and the coalesced powers of Saracen and Christian were unable to resist their powerful assault. The Christian host was overthrown in a great battle, which lasted two days, and in which the grand masters of two orders, and most of the knights, were slain. The Holy City was then taken and plundered by the invaders.

Each new disaster of the Christian arms served to rekindle the languishing zeal of the Europeans; and Louis IX. of France fitted out, in 1248, an immense armament for the Holy Land, consisting of 1800 sail of vessels, in which he embarked an army of 50,000 men. He landed in Egypt, and after storming the town of Damietta, he advanced along the sea-coast towards Cairo, when his troops were so wasted by sickness and famine, that they fell an easy prey to the enemy. The king, with most of his nobles and the remnant of his army, were made prisoners; and it was owing to the clemency of the sultan, who accepted a ransom for their lives, that Louis, with his few followers who remained alive, was permitted to embark for Palestine.

The power of the Christians in Palestine, weakened, among other causes, by internal dissensions, was now vigorously assailed by Bondocdar or Bibars, the Mameluke sovereign of Egypt and Syria. He invaded Palestine with a formidable army, advanced to the gates of Acre, and reduced the important city of Antioch, when 17,000 of the inhabitants were put to the sword, and 100,000 carried into captivity. The report of these cruelties in Europe gave rise to the eighth and last Crusade against the infidels, which was undertaken by Louis, the French king, sixteen years after his return from captivity. But in place of directing his arms immediately against Palestine, he landed in Africa, and laid siege to Tunis, which he reduced. But he perished miserably on the burning sands of Africa, of a pestilential disease, which proved fatal also to many of his troops; and thus ingloriously terminated this expedition, which was the last undertaken by the Europeans for the recovery of the Holy Land.

The Europeans in Palestine, a feeble remnant, were now confined within the walls of Acre, which was besieged by a Mameluke host of 200,000 troops that issued from Egypt, and encamped on the adjacent plain. In this, their last conflict with the infidels of the Holy Land, the Europeans fully maintained the glory of their high name. They displayed all the devotion of martyrs in a holy cause, and performed prodigies of valour. But, equalled as they were in discipline, and fearfully overmatched in numbers, by their enemies, they were overborne by the weight and violence of their attacks, and in the storm and sack of the city all either perished or were carried into captivity. Thus terminated for ever, in 1291, all those visions of glory and conquest by which so many adventurers were seduced from Europe to the Holy Land, there to perish under the complicated perils of disease and the sword. The other smaller towns which still remained in possession of the Christians yielded without a struggle to the Moslem arms, and under the religious tyranny of the infidels which succeeded, the Christians in Palestine were everywhere reduced to the lowest degree of debasement. The pilgrims who still visited Jerusalem were exposed to insult and danger; and large contributions were exacted by their oppressors for a free passage through the Holy Land. The Mameluke sultans of Egypt continued to rule over Palestine until the country yielded to the formidable irruption of the great Tamerlane in 1400. At his death Jerusalem reverted to the kingdom of Egypt, and was

Palestrina. finally subdued in 1517 by Selim I., the sultan of the Turks, under whom it has continued for more than 300 years.

In this condition Palestine remained without any remarkable event in its history, except that for nearly three centuries it was the scene of domestic broils, insurrections, and massacres, until the memorable invasion of Egypt by the French army in 1798. Bonaparte, being apprised that preparations were making in the pashalic of Acre for attacking him in Egypt, resolved, according to his usual tactics, to anticipate the movements of his enemies. He accordingly marched across the desert which divides Egypt from Palestine, and invaded the country at the head of 10,000 troops. After taking several towns, and among the rest Jaffa, where he stained his character by the atrocious massacre of 4000 prisoners, Napoleon proceeded to form the siege of Acre; and this fortress, the last scene of conflict between the Christians and infidels of former days, became a modern field of battle, in which were exhibited prodigies of valour that rivalled the most renowned deeds of those chivalric times. Notwithstanding the obstinate defence, Bonaparte persevered in a series of furious assaults against the fortress, which were all most gallantly repelled; and after a protracted siege of sixty days, a last assault was ordered, which was equally unsuccessful with all former attempts, and was attended with the loss of some of his bravest warriors. This last failure dictated the necessity of an immediate retreat, which was accomplished with difficulty, in a tedious march through the burning desert, where hardship and privation of every sort was the lot of the wayworn soldier, and the sick and wounded were left in most cases to inevitable death.

In the year 1811 a new power arose in the East,—namely, that of Mehemet Ali, the viceroy of Egypt, who, having collected large treasures and a well-disciplined army, openly renounced his allegiance to the grand signior. A war took place, in which the hasty levies of Turkey were broken and put to flight by the veteran troops of Egypt; and a series of brilliant successes added Syria to the viceroy's dominions. The people generally were disposed to hail the change of masters with pleasure, and by a well-advised and moderate system of government, Mehemet Ali might have bound them firmly to his person and his cause. But although in some respects an enlightened man, his notions of government were oriental and despotic, and the sort of European discipline and order which he had introduced into his civil and military service was chiefly valued by him as an instrument for giving more general and certain effect to his extortions. The Syrians soon discovered that, instead of being relieved from the exactions of the Turkish government, much heavier burdens were laid upon them. The forcible impressment of men for the army, and the disarming of the population, were the measures that created the most discontent, and led to such disturbances and revolts as encouraged the Porte in the design that it had always entertained, of reducing the pasha and recovering his provinces. In 1839 a Turkish army appeared on the northern frontier of Syria, and soon came into collision with the Egyptian army under Ibrahim Pasha, son of Mehemet Ali, by whom it was totally defeated, and the European powers then deemed it right to interfere to crush the ambitious designs of the Egyptian viceroy. This was accomplished in 1841, chiefly by means of a British fleet, by which Acre and other strongholds were taken for the sultan; and the pasha was at length compelled to evacuate Syria, and restore it to the dominions of the Porte. Scarcely had Syria been evacuated by the Egyptians, when the Christians, who had before supported Ibrahim Pasha, began hostilities against the Turks, while at the same time the Maronites and Druses of Mount Lebanon were engaged in fierce and bloody contests with each other; so that the Porte was unable to reduce the country to a settled state. In Jerusalem the Mohammedan population raised great obstacles to the erection of a Protestant church, in opposition to the British, French, Russian, and Sardinian consulates that had been established there; and in 1843 they proceeded to violence against the French consulate. In 1845 the insurrectionary struggles of the Druses and Maronites, who had united against the Turkish government, reached such a height that the Porte gave orders for the disarming of all the inhabitants of Lebanon; a measure which was carried out by the soldiery with much rigour and cruelty. The dispute about the possession of the holy places at Jerusalem, which began in 1850, though in itself insignificant, is of some importance, as having been one of the causes that led to the recent Russian war. The various sects of Christians, and especially the Greek and Latin churches, have been for ages involved in quarrels regarding the possession of the real or supposed localities of the great events of the New Testament history, on which their various churches and sanctuaries have been erected; and the Turkish government has been appealed to as an arbiter on both sides. Recently, however, these quarrels assumed a political aspect, from the interference of Russia on behalf of the Greek, and of France on behalf of the Roman Church. Concessions were made in 1852 to the Romanists by the Porte, which would have satisfied the French government; but within a month afterwards, a *hatti-sherif* was published in favour of the Greeks, allowing them several privileges which could not well be reconciled with those promised to their rivals. Notwithstanding these complications, a peaceable arrangement was on the point of being effected, when the Russian government interfered, and made this question one of its pretexts for a rupture with Turkey. Prince Menschikoff was sent to Constantinople nominally to effect a settlement of the question regarding the holy places, but his demands soon extended much further than this question, and affected the condition of all the Christian subjects of the sultan, so as to place them virtually under the Russian instead of the Turkish government. These demands were refused by the Porte; and the consequence was, the seizure of the Danubian Principalities by Russia. This step was followed by the declaration of war with Russia by England and France. After the conclusion of the war, the sultan published in 1856 a *hatt-humayoun* confirming the *hatti-sherif* of Gulhanie, published in 1839, and granting full liberty to all his subjects, of whatever persuasion, in the exercise of their religious rites. The political events which have recently taken place in Turkey have exercised a beneficial effect on the condition of Protestants in Syria and other parts of the empire. (D. K.)

PALESTRINA, Giovanni Pierluigi da, a most distinguished composer of music, took his surname from that small town in the Roman Campagna in which he was born. The name of his family, their station, the date of his birth, and that of his death, remain doubtful, notwithstanding the long and indefatigable inquiries of the Abate Baini, director of the Pope's chapel at Rome, whose work on *Palestrina* is the most complete and accurate yet published.[1] The probable facts stated by the abate are,—that Palestrina's parents were poor, that he was born in 1524, and that he died on 2d February 1594, aged seventy. It appears that he went to Rome in 1540, and studied music in the school established there by the French musician Claude Goudimel, the best musicians in the chief chapels of Italy being at that time natives of France, or Belgium, or Spain. In 1551 Palestrina was appointed *maestro di capella* of the Julian chapel, and was the first musician on whom that title of chapel-master was conferred. In 1554 he published his first collection of masses, four of them for four voices, and one for five. They were dedicated to Pope Julius III., who, in January 1555, appointed Palestrina one of the singers of the pontifical chapel. Palestrina had married when young, and his wife bore him four sons, the youngest of whom edited the two last books of his father's masses. When Pope Paul VI. succeeded Pope Marcellus II., he took offence at those singers in the papal chapel who were married, and expelled them on that account. One of these was Palestrina. On 1st October 1555 Palestrina was appointed chapel-master of St John of Lateran, a post which he held for about five years, and during which time he composed some of his finest works. On 1st March 1561 he improved his income by becoming chapel-master of Santa-Maria Maggiore, and held that office till 31st March 1571. In 1563 the Council of Trent having censured the profane words and music introduced into masses, Pope Pius IV. ordered this matter to be reformed. Palestrina was invited to compose a mass upon the reformed plan. He composed three for six voices. One of them (called *Missa Papæ Marcelli*) was thought so admirable that Pius IV. rewarded its author by naming him composer to the pontifical chapel, with a salary of nine scudi (about L.2) a month. Afterwards Pope Gregory XIV. increased that salary. In April 1571 Palestrina once more entered the chapel of St Peter in the Vatican, and finally became director of the

school of counterpoint formed by Nanini. In July 1580 the death of his wife caused him great affliction; and he seems to have passed the last years of his life in very straitened circumstances. He alludes to his struggles with poverty in the dedication to Sixtus V. of his first book of the *Lamentations of Jeremiah,* for four voices, 1588. He died on 2d February 1594, and was interred in the Vatican, the following inscription being engraved on his tomb:—"Joannes Petrus Aloysius Prænestinus. Musicæ Princeps." A fine portrait of Palestrina is given in the Abate Baini's work above cited. In the church style of composition Palestrina attained a degree of excellence which has never been equalled. His style is pure, noble, and flowing. His voice parts are written with the greatest skill, each part being made to sing in a simple, free, and natural manner, and using only the best notes belonging to each kind of voice; while the whole voices concur in producing the smoothest and best effect. When Cherubini taught composition in the Paris Conservatory, he analyzed and explained the works of Palestrina as models of the highest style of church music. Besides a vast quantity of music for the church, Palestrina composed two books of madrigals for four voices, and one for five. These madrigals are admirable, though too little known in Great Britain. His published works consist of thirteen books of Masses, six books of Motets, one book of Lamentations, one book of Hymns, one book of Offertories, one book of Magnificat, one book of Litanies, one book of Spiritual Madrigals, and three books of Madrigals. Many of his unpublished compositions are preserved in the Vatican Library. The Abate Baini had prepared a complete collection in score of all Palestrina's works, but there is little prospect now of its publication. (G. F. G.)

PALESTRINA (anciently *Præneste*), an episcopal town of the Papal States, on the slope of a hill, 23 miles E.S.E. of Rome. Among its public buildings are the church of Santa Rosalia, and the old palace of the Barberini family. It still contains many remains of its ancient splendour. Manufactures of woollen cloth are carried on here. Pop. 6000. (See PRÆNESTE.)

PALEY, WILLIAM, one of the most acute of English thinkers, and one of the most graphic of English writers, was born at Peterborough, July 1743. His father, who was a minor canon in the cathedral there, was appointed, while Paley was yet a child, head master of Giggleswick grammar school in Yorkshire.

Here Paley received his education under his father's eye, and early displayed the vigour of mind for which he was afterwards so eminent. He outstripped, we are told, all his school-fellows.

While making nearly equal progress in all the school studies, the special tendencies of his genius were even then distinctly marked. He took a keen delight in examining any curious pieces of mechanism that fell in his way; and on casually seeing a trial at Lancaster about a year before he left school, is said to have been so much excited by it, that he introduced mock trials as a pastime among his school-fellows. One would have liked to see him in his juvenile attempts at sifting evidence and cross-examining witnesses. —Active in mind, he was sluggish in body, and took little part in the athletic sports of his companions; he was fond, however, of long rambles among the fields; and of angling, a sport the love of which, in after life, became a passion.

Young Paley remained under his father's eye till his sixteenth year, when he went to Cambridge (1758), and was admitted a sizar of Christ's College. On leaving home his father prophesied his son's future fame,—"He'll turn out a great man—very great; he has by far the clearest head I ever met with." He made his first journey to the university on a pony, in company with his father, and has given us an amusing account of his equestrian misadventures. His father jogged on before, and Paley trotted behind. "I was never a good horseman," says he; "and when I followed my father on a pony of my own, on my first journey to Cambridge, I fell off seven times. I was lighter then than I am now; and my falls were not likely to be serious. My father, on hearing a thump, would turn his head half aside, and say, 'Take care of thy money lad.'"

During the early part of his under-graduateship Paley was more notorious for humour, social propensities, and indolence, than for diligence and application. A singular incident, which shows his force of character in a very remarkable light, revolutionized all his habits as a student. "I spent," says he, "the first two years of my under-graduateship happily, but unprofitably. I was constantly in society, where we were, not immoral, but idle and rather expensive. At the commencement of my third year, however, after having left the usual party at rather a late hour in the evening, I was awakened at five in the morning by one of my companions, who stood at my bedside, and said, 'Paley, I have been thinking what a fool you are. I could do nothing, probably, were I to try, and can afford the life I lead; you could do everything, and cannot afford it. I have had no sleep the whole night on account of these reflections, and am now come solemnly to inform you, that if you persist in your indolence I must renounce your society.' I was so struck with the visit and the visitor, that I lay in bed great part of the day, and formed my plan. I ordered my bed-maker to prepare my fire every evening, in order that it might be lighted by myself. I arose at five; read during the whole of the day, except such hours as chapel and hall required; allotted to each portion of time its peculiar branch of study; and just before the closing of the college gates (9 o'clock), I went to a neighbouring coffee-house, where I constantly regaled on a mutton chop and a dose of milk-punch; and thus, on taking my bachelor's degree, I became senior wrangler."

Such an odd sermon from such an odd preacher, at so unusual an hour, might well startle the listener; but the instantaneous revolution it wrought shows wonderful decision of character, and might have been introduced as an illustration in Foster's celebrated essay on that subject.

He took his bachelor's degree January 1763, and for nearly three years afterwards was assistant in a school at Greenwich. In June 1766 his election to a fellowship of Christ's College brought him back to the university, where he became one of the tutors of his college. Here he delivered lectures on the subjects which afterwards occupied him in his principal writings—moral philosophy and divinity. His coadjutor was Mr Law, son of Dr Edmund Law, the master of Peterhouse, who was afterwards bishop of Carlisle, and Paley's lifelong patron.

After living about ten years as college tutor, Paley resigned his fellowship, and married. In 1775 he was presented, through his friend Bishop Law, to the rectory of Musgrove in Westmoreland; to which were soon afterwards added the vicarage of Dalston in Cumberland, and the living of Appleby in Westmoreland. In 1782 he was made archdeacon of Carlisle, and about the same time exchanged the living of Appleby for a stall in that cathedral. His income was now considerable.

In 1785 he published, in 4to, his first considerable work, the *Moral and Political Philosophy.* For the copyright the author received L.1000,—a very unusual sum for literary work in those days; but the popularity which the book rapidly acquired proved that the publisher had made a safe speculation.

In 1790 he published his *Horæ Paulinæ*, which, of all his works, gives us the fullest image of the characteristics of his mind, and is certainly entitled to be called the most original.

In May 1791 Paley lost his wife, who left him with eight

children,—four sons and four daughters. He remained a widower four years, and then married Miss Dobinson, a lady of Carlisle long known to him, and much esteemed.

In 1791, at the height of the panic produced by the French Revolution, Paley wrote his *Reasons for Contentment*,—a *brochure* which he regarded, it is said, with all an author's complacency, and pronounced the best thing he ever wrote. It consists of some rather commonplace truths very well expressed, but is quite unworthy of his partial estimate of it. It has been said that his political zeal was stimulated by the hope of a mitre; if so, he was doomed to be disappointed. But, in justice to Paley, it must not be forgotten that he was not a man likely to pay court to the ruling powers, either in this or any other way, from the mere hope of preferment.[1] He who said that the "Divine right of kings was on the same footing with the Divine right of constables," could hardly hope for favour from a monarch like George III.

In 1791 the dean and chapter of Carlisle presented him to the vicarage of Addingham; and two years after, he vacated the benefice of Dalston in exchange for that of Stanwix, which was nearer to Carlisle. This was the best of the three reasons which Paley is said to have given for the change. They were as follows:—"*First*, it saved me double housekeeping, Stanwix being within twenty minutes' walk of Carlisle; *secondly*, Its value was greater by L.50 a year; and, *thirdly*, I began to find my stock of sermons coming *over again too fast*."

In 1794 appeared his work on the *Evidences of Christianity*, which has perhaps been the most popular of them all, and was certainly best recompensed. Though the court and minister were inexorable, or insensible to his claims, preferments were showered on him by the bench. Bishop Porteous gave him a prebendal stall in St Paul's; Lincoln made him sub-dean of that see; Durham conferred on him the living of Bishop-Wearmouth: altogether, these preferments yielded considerably more than L.2000 a year. If it be ever desirable to reward merits like those of Paley in this oblique way, few men have better deserved episcopal patronage, for the services he rendered to the cause of our common Christianity were unquestionably very signal.

After being made sub-dean of Lincoln, Paley took his doctor's degree, and in his *concio ad clerum* made an unhappy slip in quantity, pronouncing *profugus* with the penult long,—an offence which was duly expiated by being made the subject of some college wit's sarcastic epigram; but he had better success when he completed his exercises for his degree. In the discourse he addressed to the clergy on that occasion (one of his best), he characterizes with much ability and force the dangers and temptations which "beset the clerical character," and here and there shows a knowledge of the philosophy of human nature not unworthy of Barrow or Butler.

In 1795 Paley took up his abode at Bishop-Wearmouth. In accordance with the principles advocated in his *Moral Philosophy*, and in accordance too, it may be added, with his benevolent disposition and his wish to live in peace with his parishioners, he agreed to commute the tithes for a fixed payment during his life. The rapid rise that took place in the value of farm produce during the following years made the tenants well contented with their part of the bargain, and it is much to Paley's credit that he never repented of his.

At the solicitation of the Bishop of Durham, he consented to act in the commission of the peace, for which, in many respects, he was admirably well fitted. In his *Moral Philosophy* he has specified the magistrate's function as one, by the discharge of which a conscientious man may, at little cost, secure some of the most comprehensive ends of benevolence: and this is true; but the office requires great patience and self-control, and our philosopher, according to his biographers, was somewhat too irascible to discharge it well.

In 1800 Paley was attacked by the complaint which ultimately proved mortal, though not till after some years of much suffering. His last, and in many respects greatest work, his *Natural Theology*, was prosecuted, and in great part written, during the intervals between the paroxysms of this painful disease. No sooner was the paroxysm over than Paley resumed his work with unflagging spirit. The reader will recollect the pleasant passage in which he half makes it a question whether the delicious sense of relief from pain be not a compensation for suffering it. A calm estimate, probably, would make every one answer in the negative; but the thought seems to have been suggested in the grateful experience of recent relief from severe suffering. Paley died May 25, 1805.

The mind of Paley was acute rather than profound—discriminating and observant rather than comprehensive. If we except the mathematics, he had little aptitude for abstract science; the complex, subtle, fugitive phenomena of consciousness he had neither analytic skill, nor, we suspect, patience, thoroughly to investigate. In almost the only place in all his works—the first two books of his *Moral Philosophy*—where refined analysis of the phenomena of consciousness was specially demanded, he is generally admitted to have signally failed. When he approaches the confines of a metaphysical discussion, we see how apt he is to resile from it; in part, doubtless, from want of congeniality with such subjects, but in part also from his predominant love of the *practical*. Indeed, from the strength of this last characteristic, he would probably still have been an indifferent metaphysician, even had his talents for abstract science been much greater than they were. As it was, the sense of the practical generally decided at once the limits within which he was disposed to speculate. But within his own province—and a very extensive and most important one it is—it may be doubted whether any mind was ever more happily equipped for its functions. In all questions that involve a practical issue, and which stop short of the investigation of the metaphysical principles of knowledge and belief; questions which men must, and will, and do decide independently of the *theories* of those principles; in all questions which involve the investigation and comparison of *facts*, and just logical deduction from them,—his powers are of the very first order. Few ever surpassed him in the discovery of apt arguments for his purpose—in the ingenuity with which he could combine apparently inconsiderable and often neglected data, and make them yield unexpected conclusions—in the selection and arrangement of his materials—in the skill with which he wrought them into his truly original structures of argumentation—in the fecundity and felicity of his illustrations, or the exquisite precision and transparency of his style; and hence, on all his works he has stamped the image of his own genius, though the subjects (with one exception) were already worn thread-bare. In surveying his ground, in determining what points to assail or defend, and in marshalling his forces, he had, in military phrase, the general's eye. His works, in their whole laying out and plan—in their adaptation of part to part—exhibit not simply strong powers of logic, but constructive genius of a

[1] There was a tradition, that on the occasion of Pitt's visit to the university, soon after his becoming premier, Paley reproved the greedy court paid to the youthful minister by preaching from the text,—"There is a lad here which hath five barley loaves and two small fishes; but what are they among so many?" The story may have originated, and probably did, in some playful pleasantry of Paley; but had he thus desecrated the pulpit, he would have deserved as grave a rebuke as the venal suitors for ministerial favour.

very high order. His imagination and his wit were both tolerably active; indeed, the latter is represented as exuberant in private life, and as making him the delight of the social circle; but in his writings both these qualities are so completely *ministerial*, that there is probably hardly a single instance in all his works where an illustration is introduced to embellish or delight, or to minister to the sense of beauty. All are either exemplifications of the argument itself (*instances*), or designed to give a more graphic and precise expression to it. His style is the just reflex of his mind. It is eminently precise and luminous both as regards diction and construction: as he is never guilty of *overdoing* in argument, but contents himself with the proofs that most speedily establish the conclusion, and there stops, so it is in his style. The chief excellence of all strictly argumentative composition must of course be perspicuity; for what is called beauty of style (as regards the greater part of its elements) there cannot be much scope. Perspicuity of style, however, Paley possesses in such perfection, that its very lucidity becomes beauty. Probably no man besides ever expressed so much scientific matter as he has expressed in his *Natural Theology* without technicalities, without pedantry, in such easy colloquial diction, with such apt and homely illustrations. It is science without the forms of it.

This lucid simplicity has often led readers to undervalue Paley as a thinker: it not only produces the effect of a perfectly translucent medium, which, the more clearly it lets us see objects, the less it obtrudes itself upon us; it is like a pure stream, which refracts the light so perfectly as always to seem to the eye more shallow than it is.

There is a natural correspondence between the mental and moral characteristics of men; so it was with Paley. His intellect was neither profound nor subtle; and, accordingly, his sympathies were circumscribed. He was also without enthusiasm; and there was, in consequence, little elevation of sentiment and no vehemence of passion about him. His *Sermons*, accordingly (though we are not to forget that they were never designed for publication), exhibit plain good sense, expressed with characteristic perspicuity, but without any of the "thoughts that breathe and words that burn" which constitute true eloquence. It must be added that they exhibit a very defective perception of the deeper spiritual truths of the gospel, and the deeper spiritual anatomy of human nature. His benevolence, however, was active and genuine,—practical, like all his other qualities,—and none the worse for being of that undemonstrative character which best harmonized with his plain, direct, practical intellect. Benevolence with him was a habit, and no mere sentiment. Few were more at home in ministering to the wants of the poor and the sick, and in devising plans for alleviating the sorrows of his parishioners.—Another marked trait of his character was his equable cheerfulness. This, too, is often found in those who, like Paley, are chiefly distinguished by plain rectitude of understanding and incapacity of the deeper emotions; for profound thought and profound feeling almost always pay the penalty of fits of melancholy as the cost of ecstasies and exaltation. This elastic spirit is pleasantly displayed in many passages of his *Natural Theology*, written as it was in the intervals of severe suffering. Nothing that he saw around, or felt in himself, could damp the buoyancy of heart, which made him exclaim, amidst the rejoicing song of birds, and hum of insects, and radiant smiles of infants,—happy by immediate donation of God,—"It is a happy world after all." All he suffered seems as little to have tinged his own spirit with sadness as the spectacle of those more comprehensive miseries of the world which would have made many a deeper but less enviably-constituted mind—John Foster's, for example—pause before it gave expression to such a sentiment, or half retract it as soon as uttered.

All the principal works of Paley exhibit his chief characteristics of mind in singular perfection: it is mirrored in them. However they may differ in intrinsic value, they are all stamped nearly in the same degree with the impress of his genius. The most faulty, owing to his erroneous *theory* of morals in the first portions, is the *Moral and Political Philosophy*. On this the remarks of Sir James Mackintosh, in his *Ethical Dissertation*, make it needless to say much here. It is sufficient to remind the reader that Paley's theory does not account (nor can any such theory) for the very *origination* of the ideas of right and wrong, duty and obligation, in the human mind; notions which are perfectly unique, as much so as those which are the product of any other distinctive faculty of our nature,—and in every case irreducible to the mere conceptions of the "prudent" and "imprudent," of "profit" and "loss," into which, if the utilitarian theory were true, they should be resolvable. Sir James Mackintosh has insisted much, and justly, on the approximate agreement among mankind in their moral judgments as an argument for man's original moral constitution; but it may be remarked that even a wider divergence in this respect, a greater diversity in the moral codes of men, would not impair the above argument against Paley's theory. It is no doubt true that there is such an approximation to agreement among mankind, and the logical force of their differences is fairly neutralized by the facts Sir James insists on. Though not unimportant, and proving clearly enough some abnormality in human nature on *any* hypothesis, these differences, which are always made one of the principal arguments against the theory of an original moral constitution of human nature, form in reality no argument at all. That distinctive moral constitution is shown in the very conception of *right* and *wrong*—moral approbation and the contrary; and there is as real, though not as pleasant, a proof of man's original moral constitution when the conception is vitiated as when it is not. It would not invalidate the argument that the eye, the organ by which the notions of light and colour are conveyed, implies a distinct faculty of our nature, were it true that no two men saw just alike; nay, if one saw green where another saw blue. Very bad eyes they would be in that case, no doubt; still, that there was the perception of light and colour at all would be the result of a distinct organism to convey them, and due to no other sense. In like manner, it may be argued that, in the present condition of man, his moral perceptions may be often vitiated, and yet that the very existence of such notions as *obligation*, *duty*, and *remorse*, show a distinct moral constitution of man, whether it be the result of some single faculty called a "moral sense," or as a distinct result of the reciprocal action of many faculties.

It is not to be denied that the want of elevation and nobility in Paley's ethical principles has unfavourably affected some of his practical applications. It is impossible to read his lax observations on "subscription," his tender dealing with what are called "white lies" and other peccadilloes, without feeling that his theory has in some cases warped his decisions, and in others has injured the *tone*, even where the decisions are not erroneous.

He seems to have formed his ethical theory very early. The subject of his Latin dissertation for the senior bachelor's prize (in 1765) was "a comparison between the Stoic and Epicurean philosophy in their influence on morals," &c.; and he awards the superiority to the latter. It must be added, that on certain occasions in life he too obsequiously followed his own theory. One of the theses he proposed (in 1762) to defend in the schools was, that eternal punishments are inconsistent with the Divine attributes; but having learned that it would give umbrage, he accepted, with grateful alacrity, the suggestion of Dr Watson, that he could insert "non" in the proposition, and take the

Paley. other side; which he accordingly did, and argued for the contrary of his own convictions with great eclat and success. It cannot become any man thus to trifle with his genuine sentiments. In like manner, when asked to sign the petition for a relaxation of the terms of subscription, he gave as his reason for refusing, that (though he heartily approved of the object) "he could not afford to keep a conscience." It would be unjust to press a joke, such as this must have been, too far (for Paley *did* "keep a conscience"), but it is impossible to help feeling that a want of due sensitiveness—a certain moral laxity on some occasions—was the consistent fruit of a moral theory which necessarily turns the thoughts too closely on the "profit" and "loss," the advantages and disadvantages of actions, and invites to a too solicitous casuistry wherever it is not absolutely shameless to exercise it.—Apart from the vice in the *principles* of his ethical theory, the treatise is not unworthy of Paley; and many portions display all the acuteness, justness of thinking, and felicity of style which so eminently distinguished him. His illustrations of the institution of property and its advantages—his remarks on the best modes of exercising benevolence—his contemptuous exposure of the excuses for not practising it—his chapter on anger and its "*sedatives*"—these and many other portions are admirable.

It is the fashion with infidelity now-a-days to speak of Paley's "Evidences" as *passé;* as having little or no relation to present controversies, and as utterly inadequate to meet those more subtle and more efficient methods of refuting the truth of Christianity, which modern astuteness has discovered. This is a stock fallacy with many infidel writers; and by mere repetition it has, among the young and ignorant, often passed current. We maintain, on the contrary, that the supposed new methods differ from the old more in form than substance; and that when they differ in form they do not affect the substance of the argument. Almost everything in the new methods that has any real bearing on the controversy has been long since propounded to the world. Nor, if we reflect, could it well be otherwise. An *asserted historic fact* is not, like a Chinese puzzle, capable of being put together in a thousand ways. Christianity professes to be *historically* true; and the only way it can be shown *not* to be so, is to show that its alleged facts are no facts at all. Now, the *mode* of doing this admits of no great choice; changes of form or detail there may be, but there can be little more. For example, it may be contended by one that Christianity originated in imposture; by another, that it was simple honesty mistaking its facts (very simple, indeed, it must have been, if it could mistake *such* facts); by a third, that it was a slow growth of popular credulity out of a slender nucleus of truth; by a fourth, that it was a result of all these. And all these hypotheses, in various ways and in different degrees, were given long ago to the world: the elder infidels depending more on the coarse imputation of fraud practising on credulity, though not to a wasteful exclusion of other less offensive suppositions on particular occasions,—the modern opponents, with improved politeness, rather dwelling on innocent self-deception and honest credulity in the founders of Christianity; though here again we find no absolute lack of infidels who prefer the curt effrontery of the elder gainsayers. But the supposition of ***these illegitimate motives rather than those*** in the authors or propagators of Christianity can constitute no variation in the *arguments* for confuting its claims as history. The mode in which the assailant acts may vary on that supposition; it may make him more cautious on this point or bold on that; or induce him to reject, if he adopt one hypothesis, some arguments which he would use if he adopted another; but it cannot affect the only point of any real importance,—namely, the value of the arguments which are to prove that Christianity is ***not historic***. As to this, it does not matter a rush what are the sentiments of the assailant as to Christ's character or that of the apostles; it is a mere question of his insolence or urbanity, his charity or malignity, about which it is hardly worth while to carry on controversy. What he has to do is to show either that the facts of Christianity are *à priori* incredible, or incredible from their intrinsical inconsistency and contradictoriness, viewed *as history*. Now, when that is attempted, we invariably come to essentially the same methods as were employed long ago. A few arguments may be withdrawn, disabled to the rear, and a few new recruits brought to the front; and more or less strategical skill may be found in marshalling the forces; but the staple of the method is, and must be, the same. If it be said—"But are you not doing injustice? Though many of the modern objections to the current Christianity are, it is true, old objections,—especially the alleged discrepancies, and *à priori* objections to miracles,—and are attended with the same result, even the elimination of all the miraculous facts and all the peculiar doctrines, yet do not the objectors say they are Christians still? Christianity is accepted by them in a certain rationalist or mythical sense. You have not a miraculous fact left, it is true, or a doctrine of Christianity which distinguishes it from the philosophy of Seneca or Epictetus; but that is all: if you have not Paul, you have Paulus; or Christ is simply 'turned into an Hegelian.'" We answer, that to get rid of the facts, these writers are first obliged to resort to the *old methods* under new disguises; and, as just said, it matters not in the interest of what particular faction of their own they thus attempt to get rid of them; only it may well be asserted that those who pretend to retain Christianity after having critically juggled it out of all its asserted facts and doctrines, and its founders out of all their brains in having believed them, are by far the worst infidels of all. They come with the rest of the rabble, "with swords and staves for to take Christ;" but they come by night, they come among the chief priests and scribes, and they betray him with a kiss.

When, therefore, opponents affirm, "The modern apologists rely on the obsolete and exploded methods, the new and more subtle attacks are evaded," it is wise to deny it, and challenge explicit proof. On the contrary, it may be shown, if we can but get them to details, that the arguments by which modern infidelity assails Christianity are, in substance, what were propounded long ago. The infidel hypotheses as to its origin are indeed various, and, unhappily for its opponents, very contradictory; but the arguments by which it is attempted to prove its unhistoric character are necessarily the same.

Thus, it is not easy to see that the *à priori* argument for the incredibility of all external revelation, based on the modern "spiritual deism," differs essentially from Lord Herbert's old-fashioned argument founded on his natural deism; nor does it matter, though the one calls the responses of the internal oracle "spiritual intuitions," and the other "innate ideas." There is plenty of scope for a "revelation," as human nature is now constituted, in confirmation or rectification of either; for never, judging by results, was any oracle less oracular.

Similarly, the assertion of the *à priori* incredibility of miracles, so often and so perseveringly insisted on in our day, as utterly inconsistent with the uniformities of antecedence and sequence in the phenomena of nature, in no way differs from the old-fashioned talk of their being "contrary to experience, and contrary to reason," which Bolingbroke and Hume, and multitudes more, expatiated upon in the course of last century; the fallacy in either case being the same, and more worthy of children than philosophers,—namely, that what we have not seen never was, and that the same uniformities of experience which we have been familiar

with, have ever existed and ever will. Old or new, the argument may well be called a fallacy, for it can never be consistently held by any class of minds, not even by the atheist; for, to him who denies that there is any presiding Intelligence which has ordained that things should be thus or thus, there is no reason why he should not believe in the possibility of any jumble of antecedents and consequents; that is, in the possibility of any number of miracles; rather he should congratulate his good fortune that he does not meet with them every day,—that he does not see men born with two heads instead of one, and going on four legs instead of two. But, at any rate, no *theist*,—no one who believes that man is not "an eternal series" (no matter whether he believes that he sprang out of the dust or was slowly developed out of a tadpole,—a monkey being one of the intermediate links), ought to insist on the *à priori* incredibility of miracles; for whether the phenomena he is compelled to admit require moments or centuries to bring them about, makes no difference as to their *character;* they as much transcend all our present experience, and as much contradict it, as any miracles that can possibly be found, whether in the New Testament or elsewhere. Doubtless we should all stare as much at seeing a tadpole transmuted into a man, as at seeing a man compacted out of the dust. It is difficult, therefore, not to doubt the logical honesty of any theist, old or new, who urges this objection, unless he believes that his "experience is the measure of all things," and that what is has ever been, and will ever be.

Again; as to the *discrepancies* that have been so much paraded in our day, the principal of these have been insisted upon from the very earliest times, and have been in all time among the stock arguments of infidelity. With what success we may see; they never have prevented, and never will prevent, the great bulk of investigators from feeling that, be they solved or be they not, they are of no avail against the prodigious accumulation of positive historic proof in favour of Christianity.

We have said that Paley's work is still a sufficient answer to the generality of modern arguments against Christianity. Even Paulus and Strauss, so far as Christianity is really assailed by any argument which attempts to prove its unhistoric character, only use the old methods; as for their *own* hypotheses,—utterly contradictory, by the way,—for accounting for its origin in defiance of history, Paley of course never dreamt of them; nor is it a matter of much consequence, for they are just becoming (one of them has become) a by-word and laughing-stock in Germany itself. Not only are they so incoherent with each other, but they imply such a dreadful compression and torture of the understanding of any reasonable creature who attempts to believe that either does really give the rationale of the Christianity of the New Testament,—both so aggravate all the difficulties of its origin, supposing it to be what they make it,—that there is not one man out of a thousand who would not sooner receive the entire New Testament, or reject it entire, than submit to the humiliation and bondage of such exegesis. It is often perfectly ludicrous, even as applied to single passages; but to go through the whole New Testament, reading plain narratives backwards or crosswise, or any way except the plain way,—dissolving facts into mistakes and myths,—is beyond all human patience. Take, for example, a single case. Let us hear how a rationalist, by no means the wildest of them, proposes to account for the history of the conversion of St Paul.

According to his account, Saul, the persecutor, must be supposed to have left Jerusalem with all the bigotry, and in the savage mood, imputed to him in the history and acknowledged by himself; with the conscientious self-approval of that pious work in which he was engaged, and which he accounted an honour,—a zeal, no doubt, as in all like cases, inflamed by recent excesses, and chafed by opposition. As he is journeying along, he is led, quite as a natural thing, and in the way of self-dialogue, into a train of reflection on the enormity of his conduct,—that conduct which he deemed but the moment before so honourable;—on the innocence of the Christians, whom he deemed but yesterday traitors, apostates, and rebels, to the ancient theocracy; and finally on the excellence of Christ, whose image to Saul must have been that of a man who had suffered on the gallows,—for such was the cross to the imagination then, however hallowed now,—the just reward of his blasphemous presumption! Now, before proceeding further, one thing is clear; that if this gratuitous theory of the persecutor's change of mood, utterly unsupported by a single syllable of history, and utterly inconsistent with the conditions of a human mind in the state of the zeal-blinded and conscientiously-bigoted apostle, be received, it must be received as an express revelation from the rationalist school; and whether Paul ever received any revelation from Christ or not, it is certain that Paulus or his friends must have received some from St Paul.

But this is not all, or rather, it is a small part of what must be admitted, if we resolve on getting rid of the supernatural, and yet leaving St Paul a man in his senses; or, perhaps, it would be more proper to say, he must be supposed a much greater fool still, in order to leave him an honest man.

Just then, at this fortunate nick of time, and while the mind of the apostle is spontaneously softening towards Christianity, a thunder-storm occurs,—one of those signal blessings, without which a *rational* interpreter of the New Testament cannot get on for more than a few pages together; and the apostle strangely imagines that it lightens revelations, and thunders in Syriac or Hebrew; and though very much frightened indeed, answers the Syriac or Hebrew thunder in Syriac or Hebrew as grammatical as its own; and is again replied to in another well articulated clap of three or four sentences, directing him where to go and what to do, in the coolest and most comprehensible way. Surely if the lightning left Paul blind, it must have made his hearing uncommonly acute!

Such is the *natural* way in which rationalists propose to account for the apostle's conversion, and yet leave him a sincere and honest man; but it surely leaves him not only bereft of the light of his eyes, but of the light of his understanding also,—as very an approach to downright idiocy as any fanatic that ever lived. Can this be he who has led the world astray, and turned it upside down? Can this subject of weak hallucinations be the man on whose words so many intelligent, wise, and learned men of different ages and countries have hung as the accents of genuine inspiration? Can this be he whose writings and conduct everywhere proclaim zeal indeed, but a very masculine understanding also,—great prudence, self-control, and discretion? Can this be he who is one of the closest reasoners, and who, in the treatment of all practical questions, exhibits a sobriety and justness of thinking which have been the admiration of the world?

Is it possible for a man to go on interpreting thus? No wonder that the rationalist hypotheses have become a thing to point at. Nor is the Straussian theory, invented to supplant them, any better.

Who can believe, for example, that the intensely vivid and natural scenes of the Gospels and the Acts are myths unconsciously growing out of incidents and associations connected with the Old Testament history? Who can believe that the myths thus formed (if any could have been formed in such an historic age) would have been of so intensely *un*-Jewish, or rather *anti*-Jewish, a character; that they would have been characterized by such unity; but above all, that they would have been swallowed by the world at large as veritable *history*, and continue to be so received,

though containing, if myths at all, marvels and wonders more astounding than poet ever feigned!

It may be safely predicted, that Paley's work will be still read and admired long after these and other equally extravagant theories have passed into oblivion. The work is not, as too often represented, confined to the "External Evidences" alone,—much of it is given to the "Internal" also; and the chapters on the Morality of the Gospel, on the Identity and Originality of Christ's Character, and on Undesigned Coincidences, are equally full of force and beauty.

The *Horæ Paulinæ* is the work of Paley which displays most originality. As to the works on *Natural Theology* and the *Evidences*, it is in the general construction, the masterly manner in which materials, for the most part already collected by others, are built into a fabric, that the author's inventiveness is chiefly seen. But the *Horæ Paulinæ* is a felicitous thought, felicitously wrought out. There is indeed a pregnant passage of Doddridge, in which he speaks of the reciprocal support which the undersigned coincidences between the Acts and the Epistles give to the historic credibility of both; and another, still more general, in the *Pensées* of Pascal, hinting a similar thought in relation to the Gospels; but there is no proof that Paley saw either; while the extraordinary sagacity with which he has dragged latent coincidences from their lurking places, and shown correspondence where none had before suspected it, is all his own. If he had seen such hints, it would as little have abated his claims to originality, as the striking passage from Origen, prefixed to the *Analogy*, detracts from Butler's. But it was honest, as Sir J. Mackintosh says, in Butler to place it there; and if Paley had really had his work suggested by the passage in Doddridge, one would hope that he would have done the like.

The greatest work of Paley, taking it altogether, is undoubtedly his *Natural Theology*. It is true that Derham, Ray, and others, had done much before him, just as Lardner had been his pioneer in relation to the *Evidences*; but in either case previous writers were to Paley only what Hiram, King of Tyre, was to Solomon; they prepared the materials, of which Paley reared the temple.[1]

Such is the skill with which the *Natural Theology* is planned and executed—such the felicitous selection and disposition of the materials—so apt are the examples and illustrations—so luminous the expression—that, to a youth of intelligence, few novels are more interesting. Paley's survey of the ground, too, and the limits within which he resolved to construct the argument, show great logical sagacity. Clearly seeing that if the immensely varied and complicated "adaptations" of the universe can be shown to have originated in conscious intelligence, it will be difficult not to grant all the concessions which theism asks for; he avoids all the darker, especially the so-called *à priori* methods, though freely leaving any such methods open to those who choose to employ them, or who can profit by them. He therefore bends his chief energies to exhibit the indications of *design* in the universe, and for this purpose nothing can be more judicious than his choice of examples. Sagaciously perceiving that the phenomena of astronomy, though best calculated to give comprehensive views of the power and wisdom of God, *supposing His existence admitted*, are, from their vastness, apt rather to confound than aid conception, and, from their comparative simplicity, less obviously the fruit of design, he takes his chief examples from animal mechanism and physiology. His illustrations are drawn from ordinary objects, from every-day life, from the road-side, and are expressed in the most colloquial language. His descriptions of the eye, of the joints, of the process of digestion, of the circulation, of the eye of the mole ("a pin-point in a cushion"), of the contrivances for the lobster's changing his shell ("by which he takes off his boots"), of the specific lightness of the bones of birds (which he recommends the reader to verify "the next time he is engaged in picking the wing

---

[1] A vehement charge of comprehensive *plagiarism* was some years ago preferred against Paley. It was alleged, that for the method, materials, and illustrations of his *Natural Theology* he was mainly indebted to a work by Dr Bernard Nieuwentyt (a Dutch philosopher), which, under the title of the *Religious Philosopher*, was translated into English in 3 vols. 8vo, 1718. The only instance of plagiarism, however, given by the accuser, is the "watch" illustration with which Paley's work commences. Hence it is argued, that Paley was indebted for his "*argument*" to Nieuwentyt. If indebted for anything, it is, of course, for the *illustration*, and not the argument, which was independent of the particular exemplification chosen, and might have been illustrated by half a dozen instruments of art just as well. It is not wonderful, however, that the "watch" (at once so familiar and so well adapted to the purpose) should have been employed; and if there is any special merit in *first* employing it, neither Nieuwentyt nor Paley can lay claim to that merit; it was employed, for example, by John Howe in his *Living Temple* (part i., ch. iii.) for the same purpose of illustrating the argument from design.

But certain *coincidences of expression* are also insisted on as tending to show that Paley had read the passage in Nieuwentyt. It is very possible; for Paley refers to his work in one place, and thus shows that he did not wish to conceal that he had been hunting for materials there as well as in the works of Derham, Ray, and other writers, to whom, in general terms, he acknowledges his obligations. But whoever reads the parallel passages in the two writers, and compares the tedious diffuseness of the one with the point and vigour of the other, will feel, that if the particular illustration was suggested to Paley by the Dutchman, everything in the passage which one would care to claim for Paley is still his.

In fact it is absurd to charge Paley with plagiarism for having selected matter from other writers; his whole work proceeds on that supposition; it is the manner in which he has employed his materials (in themselves common-place enough) that stamps his work as original. The *facts* of science he deals with, he did not *discover*; he knew perfectly well that he must be indebted for every one of them to others. But the same charge of plagiarism might be brought against any formal treatise either of science or history, for nine-tenths of the substance of it must exist in previous writers.

Such charge, if it had any force at all, might much more reasonably be brought against Paley for the use he has made of Derham and Ray; for he is more indebted to these than to the Dutchman. But he who is at the trouble of comparing them with Paley will soon find, that though the materials must of necessity be much the same, the interval is wide enough to leave Paley's originality, in all that is really claimed for him, unquestionable.

If anybody suspects that Paley has been indebted to Nieuwentyt for more than to Derham and Ray, we fancy a very slight inspection of the *Religious Philosopher* will undeceive him. It is a work of considerable scientific attainment, considering the times; but there is neither just method nor co-ordination of parts in it; it rambles over the whole field of human knowledge; it exhibits none of Paley's exquisite tact in selecting and rejecting materials in relation to their aptness for the purpose; it contains a great many crudities and not a few errors, both as regards fact and inference (the author, for example, questions the truth of the Copernican theory, and doubts whether the doubt can ever be decided); while the style is for the most part diffuse to tediousness. We have no hesitation in saying, that if, out of these three ill-compacted volumes, Paley had evoked such a work as his *Natural Theology*, by selections, by rejections, by condensation, by re-arrangement, and by diffusing over the whole the vivid lights of his vigorous mind and style, his claims to originality would have suffered as little abatement as that of Shakspeare (on whom a similar charge was once fastened), because in a few of his plays he has condescended to make use of materials of inferior dramatists, and turned by his magic touch their lead into gold.

The truth is, as just said, that the merit of Paley's work is that of having wrought materials, open to everybody, into a beautiful fabric; and to blame him that his materials were got from other quarters is much as if it were charged upon a great architect that his stone was not of his own quarrying, nor his bricks of his own burning.

The impress of Paley's very peculiar mind is on this work as on all the rest, and would alone show that it was no plagiarism, unless

of a chicken"); these, and many similar felicitous passages, will immediately occur to every reader. Painting by words has rarely been carried further than by Paley in many of the graphic passages of this masterly treatise.[1]

The argument, as he says, and as we all know, is *cumulative;* and every new instance of adaptation augments our conceptions of the Divine power and wisdom; but the *principle* of the argument is as well established by fifty examples as by five thousand, and to an ordinary understanding is more likely to appear conclusive; for multiplicity and complexity of "adaptations" will add nothing to the clearness of the reasoning, while they may easily bewilder and confound. Particular examples *must* always be taken; and it may be doubted whether advancing science will ever find any, for ordinary readers, at once so comprehensible and so much to the purpose as those Paley has selected.

Equally just and cautious are the observations of Paley on the mode in which the argument bears on the "Divine benevolence," the transition to which, from the indications of power and wisdom, is confessedly of some difficulty in the theistic argument. Contending that the indications of the former attributes are unlimited (whether illimitable or not) in extent and variety, he contents himself with showing that the immensely preponderant evidence, the *direct* and *obvious* purpose of almost all the "adaptations" in nature, indicates the Divine beneficence also. But he does not deny or evade the difficulties of the subject. The widely-extended phenomena of *evil,* for the permission of which we must believe, but cannot see, that there are sufficient reasons, will always *limit* the argument in this direction, till we come to higher illumination than Reason alone affords us.

Various objections have been taken in these latter days against Paley's book, to which we must make a reference, though it must be brief.

Some theists complain that he does not take *other* methods—that he does not do *this,* that he does not do *that;* that he does not appeal to man's moral instincts, to his intuitive convictions of a Deity, sense of the infinite, and so on; that he is busy rather about the "means and machinery" by which the Deity works, than the "ends for which He works;" that he is more busy about the "reasons of belief," than the "object of faith;"—with much more to the same purpose, or rather to no purpose; for surely the question ought to be, not what a theist can accept as a sufficient dissertation on the Divine Existence and Perfections, but what an atheist will find it most difficult to evade; nor, again, whether a theist may not prefer another line of argument for himself, but whether he can suggest any which an atheist will find it less difficult to understand and embrace;—in other words, whether Paley does what he intends to do, and whether what he intends to do, be, with *reference to those whom he addresses,* the best adapted to produce a conviction of the existence of a personal Intelligence that has constructed and presides over the universe. If man can be brought to admit his argument, that one admission will pave the way for every other involved in the ordinary theory of theism. Nor, probably, was there ever a man who, admitting that of all the stupendous and complicated phenomena of the universe there has been an adequate personal intelligent Cause, hesitated long to admit all the corollaries to which his moral instincts, and the intimations of the Infinite within him would train him on; which then and then alone, cease to be whispers, and become articulate. He would feel little difficulty in inferring that this supreme Power and Intelligence were not only unlimited, but illimitable; and though he could not prove it (else he would be infinite himself), he would never doubt it. And even if any one, conceding a self-subsistent intelligent Cause of all things, possessed of power and wisdom adequate to account for their existence and conservation, were silly enough to deny His infinitude (of which, since his whole faculties would be lost long before he could embrace the dimensions of the attributes he *did* acknowledge, he could never judge), there would still be a GOD to *him*—a being known as such by the only proofs by which we can ever *practically* know that there is a God at all; known as the Creator, the Governor, the Disposer of all things. To *us* that is infinite which is without limit; to demonstrate the illimitable is beyond us; and if to *demonstrate* that God is infinite be necessary to a knowledge of Him, only God can know that God exists at all.

Some will say there is no better way in this controversy than that of appealing at once to a direct intuitive consciousness of an infinite God? But what if atheists deny that they have any such? What if they affirm that if there be any such voice within, it is, by itself, a whisper, or inarticulate? What if the majority even of theists say that such whispers are confirmations when made distinct, but are not first-hand grounds of conviction? What if they say that their convictions are so far dependent, at the very outset, on this question of the "Order" of the universe, that supposing confusion reigned in the natural world while the mind retained all its present powers (were that possible), they doubt whether any "intuitions" they have, would have satisfied them of the existence of a Deity, or even induced the faintest suspicion of one?

However, if any think some other way, *à priori* or otherwise, more effectual, Paley leaves people to take it. For ourselves, we do not believe there is any mode of *argument* so likely to meet the case of those *who profess to be atheists,* nor one which gives them so much trouble to reply to or evade. If any one choose to make the experiment with other methods, he will find, we suspect, that considerations which will well serve to enlarge, exalt, or intensify our belief, when once Paley's conclusions are admitted, are easily evaded if insisted on alone. The argument from design is the one which, in all ages and nations, has been the most efficient for conviction,—the argument which, as the philosopher and the vulgar, the heathen and Christian feel, leaves man "without excuse,"—which gives point to the question, equally understood by science and ignorance, "He that formed the eye, shall He not see? He that planted the ear, shall He not hear?" "The invisible things of God from the creation of the world, are clearly seen, being understood by the things that are made, even His eternal power and godhead."

The argument from the *moral* constitution of man is indeed equally strong, and more direct. But all one can do is, to appeal to the atheist's conscience; and if he denies that it is like ours, argument is at an end. And certainly he is as able here as anywhere else to take refuge in chance as accounting for moral as well as other phenomena; and it must be added, that it is too often the part of his nature with which man is most inclined to sophisticate.

Another objection recently taken up with much logical formality by some theists, is, that not "marks of design," as Paley urges, but "order" in the universe, is the great point to be insisted on; that it is this which renders the argument valid. We cannot say we see much in the distinction. That which gives force to the consideration of "order" in the world is that also which gives force to

all of them be so. We have said nothing about the moral improbability of Paley's being *consciously* a plagiarist; but, considering the entire character of the man's intellect, it is about the last meanness of which we should suspect him.

[1] Paley's homely science, in these and other passages of his great work, is beautifully illustrated in an article on the "Works and Character of Paley," inserted in the *Quarterly Review,* vol. xxxviii., pp. 305–335.

"marks of design;" it is because what we call order indicates "design" that we so call it. A system which discloses "order" must disclose adaptations of part to part, and of subordinate parts to the whole, and therefore "design."

Another and more subtle objection is, that whether we call that which justifies Paley's conclusion the evidences of "order" or "marks of design," "Paley does not sufficiently investigate the metaphysical principles of belief which impel the human mind to infer intelligence from such indications. It may perhaps be said that he considered this both beyond his province, and not at all necessary. But it may be affirmed, that man, in so inferring, acts upon the strictest principles of induction, and, unless the very constitution of his mind be altered, must, *whether his conclusion be right or wrong*, so infer. Man sees that in all the products of intelligence he *can* examine, these marks of design are found; where intelligence, he is sure, does *not* act, he sees the marks of *design wanting*. It is inevitable with him, therefore, to think it infinitely probable, when he meets with "marks of design" in any object, that they are due to intelligence, and not unconscious chance or necessity, or unconscious anything else. If, to-morrow, men met with any works as evidently designed for a purpose, as a watch or a steam-engine, but so completely beyond any present development of human power as to cause doubts of their human origin, and so unlike those of nature as to cause doubt whether they had the same origin with these, there is not one in a million who would not at once infer that intelligence produced them, though what sort of being it was in whom that intelligence resided,—whether he had two heads or one, seven senses or ten, six pairs of eyes or twenty,—we could not tell from the "marks of design" alone. Familiar with multitudinous products, possessing certain similar characteristics, which *are* the fruit of intelligence; and failing to see, where we know that intelligence does not act, any such products; men would at once infer, as the infinitely greater probability (and this, on subjects where *demonstration* is impossible, is to them *certainty*), that such newly-found specimens of "adaptations" as we have above imagined, were due to intelligence; just as confidently as Robinson Crusoe inferred, when he saw the solitary imprint of a footstep on the sand (though he had seen no traces of anybody having been on his island till that moment but himself), that it *was* a print of a foot; and did not begin to speculate as to whether it was not *possible*, though infinitely improbable, that some chance motions of the winds and waves might have produced the ominous impression. It is much the same with the phenomena of nature. From what we know of *analogous* phenomena, we cannot but ascribe them to intelligence, if we act on the principles of the inductive philosophy at all. Hence, as before said,—whether the inference be right or wrong,—thus men have always inferred, and thus they always will; and so the atheistical hypothesis, even if true, is certain of rejection. The evidence, though not demonstrative, is just as sure as that which leads us to believe that if a man throws sixes fifty times running, the dice are loaded. This, too, suggests the answer to another objection, to which a passing allusion may be made. It is that urged by Hume, and, with all his customary plausible subtlety, before Paley wrote. He admits the validity of the ordinary mode of reasoning as applied to our fellow-men, and to any works of theirs, but pretends that we cannot reason similarly in relation to a work (if it be a work) so *unique* as the universe; to effects so immeasurably beyond our adequate comprehension. "We have never seen," he says, "the great Artificer at work." The answer is (as Chalmers and many more have justly said), that it is not necessary that we should see "the Artificer at work," or even comprehend his work as a whole. Men, in general, reason just in the same way of that which exhibits *indications* of purpose and design, whether they have ever "seen the artificer at work or not;" and would do so even if, in a millionth case, such *indications* did *not* originate in design. It will not be denied that they thus reason when they see a machine or an instrument evidently so constructed as to subserve a given purpose, though they may never have seen one like it before, and though they may never have seen any artist at work on any part of it. The atheist may say they have seen *analogous* things done; the answer is—Just so: and men reason in the same way to the intelligent origin of the works of creation. He will perhaps rejoin, "But they have seen very *similar* things done." We answer, It may be, and sometimes is, the case, that there is less similarity between certain instruments of art and certain other instruments of art,—for example, an air-pump and a microscope,—than between certain instruments of art and certain instruments of nature, say an eye and a telescope; but the indications of design in the former case would be quite sufficient to settle the question of an originating Intelligence; why not in the latter?

Another favourite argument of many modern atheists is, that if any thing at all be inferred as to the attributes of an unknown Cause of all things, from any analogies in ourselves, we must infer that God not only has power and wisdom, but an organization also like ours; that he acts as we do; and that his power and wisdom must be manifested in similar ways; so that between Hume's argument and this, it is impossible atheism should fail. "You can infer nothing," says Hume, "respecting the author of a work so unique." "If you infer anything analogous to man in Him," say these astute opponents, "you must infer everything analogous."[1] To this ridiculous argument it might be sufficient to ask whether, if a man saw an exact imitation of a bird's nest, without positively knowing it to be an imitation, and so did not know whether it was the work of a man or a bird, he must infer that, because whoever made it must have had *some* properties analogous to those of the bird (otherwise there would not have been the same work), he must necessarily have wings and feathers also!

The editions of Paley's works, separately and collectively, are numerous. The edition of the *Natural Theology* by Lord Brougham and Sir Charles Bell is too well known to require commendation. The fullest account of his life is that by Meadley; but it is not worthy of its subject. (H. R.)

PALIANO, a town of the Papal States, in the province of Frosinone, 7 miles N.W. of Anagni, and 32 E.S.E. of Rome. It is surrounded with walls of considerable strength; and contains a large baronial castle, which was for a long time occupied as a residence by the powerful Colonna family. This family was descended from Pierre Colonna, a vassal of the pope in the eleventh century, and counted among its members Pope Martin V., as well as numerous prelates and generals. Pop. about 4000.

[1] Indeed, it is a favourite misrepresentation of theirs, that the language of writers on natural theology, in consistency with some supposed logical necessity, degrades the Deity into a laborious "mechanic." The answer, of course, is, that it is a mere misinterpretation of the obvious meaning of these writers. All they mean to assert is, that there must be power and intelligence in the supreme Cause of all, proportioned to the production of the phenomena ascribed to him; just as there must be in man, proportioned to the phenomena of *his* power and intelligence; but though, in expressing this, they necessarily use figurative language derived from the analogy of man's nature, they plainly do not intend to imply that the *modes* in which wisdom and intelligence on the part of God and man are respectively exerted or manifested are the same; or that what is *long-sought, laborious, and successive* in man's mind is at all so in God's. And as this is the meaning of these writers, and their sole meaning, so it may be doubted whether there ever was an atheist who really misunderstood it.

PALIMPSESTS.

Palimpsests.

PALIMPSEST (in Greek παλίμψηστος, a word formed from πάλιν, *again*, and ψάω, *I wipe*, *cleanse*, or *rub*), is a term applied to a manuscript, from its having been twice cleaned or twice prepared for writing. The name has been supposed by some etymologists to be derived from the *obliteration* or *erasure* of the original writing; but it is rather founded upon the *re-polishing* (ψάω), or *re-preparation for writing*, of the parchment or other material on which the original had been written. It is easy to remove the traces of writing from parchment by rubbing it with pumice-stone or some similar substance, especially if the writing be of some antiquity; and if the surface be afterwards smoothed and polished, no one, by merely looking at it, would suppose that it had ever been written on. The practice of thus preparing parchment and other writing materials a second time for use existed among the ancients; and the material so re-prepared was known by them under the same name of palimpsest; but they also applied that term to leaves or books which were so prepared that one writing could easily be expunged to make room for another, and which were used by authors for correcting their works or submitting them to revision. In this sense palimpsests are mentioned by Cicero, Plutarch, and Catullus. Cicero (*Ad Familiares*, vii. 18) praises the frugality of his friend Trebatius in writing upon a palimpsest, but at the same time playfully expresses his wonder as to what may have been the original writing, which could have been of less importance than the letter for which it had been displaced; and Catullus (xxii. 5) ridicules a bad author for not writing his works at first on palimpsests, but entering them at once, crude and uncorrected, in fine and costly books. In a word, the palimpsest alluded to in these and similar ancient authorities was one of the devices to supply the place of the modern slate or scribbling-book, and served the same purpose as the wax tablet (*tabula cerata*).

There seems little doubt, however, that, besides this temporary expedient, the practice of preparing parchment or papyrus a second time for permanent use, and of writing short pieces, and even entire books, upon such material, was well known in classic times, not only among the Greeks and Romans, but also among the Egyptians. (Wilkinson's *Egyptians*, iii. 151.) But when it is remembered that, except the charred papyri of Herculaneum, and the funereal rolls of the Egyptians, no actual remains of the writing of the ancients have reached our time, it need hardly be said that no palimpsest re-written in the classic period has yet been discovered.[1]

The palimpsest manuscripts which have proved so valuable a mine for the research of modern scholars are of more recent date, and had their origin in the dearness and scarcity of writing materials from the seventh century downwards. During the early Roman empire, the comparatively abundant supply of papyrus from the Egyptian market precluded the necessity of having recourse to what was, at best, the tedious and clumsy process of re-preparing the material already used; and from the time when Theodoric the Great, in the beginning of the sixth century, abolished the duty on the importation of papyrus, the scribes and copyists of the West confined themselves in great measure to its use, except for more solemn and important documents. But at a later period, when the complete division of the empire rendered the intercourse with the East at once difficult and irregular, the old expedient was revived; and as, in the anarchy consequent on the successive occupations of Italy by its barbarous conquerors, the ancient arts and manufactures fell into decay, and the home production of parchment became exceedingly limited, it came to pass at last, when the Saracen conquest of Syria and of Egypt deprived Europe entirely of the papyrus, that the art of cleaning and re-preparing parchment already written upon furnished almost the only writing material sufficiently cheap for the uses of the less opulent copyists of the West. And hence it is that the practice of copying upon re-prepared parchment, if we are to judge from the specimens which have reached our time, came into use at a somewhat earlier period in the western division of the empire, where the want of the papyrus was earlier felt. Re-written Latin manuscripts are met with which appear to have been re-transcribed so early as the eighth, and even the seventh century; but in the Greek palimpsests the second writing commonly dates no earlier than the eleventh, and even the twelfth or thirteenth century. It has commonly been supposed that this practice of the mediæval scribes was the occasion of a vast and reckless sacrifice of ancient manuscript; and many writers have ascribed to the demand which it occasioned, coupled with the imputed indifference, and even hostility of the period towards ancient learning, that wholesale disappearance of so many Greek and Roman classics which modern scholars have to deplore. But the palimpsest manuscripts hitherto discovered furnish little evidence of any intentional destruction of *perfect* ancient writings. All the remains of Greek and Roman literature contained in the very largest palimpsests which have been deciphered, or which are known to exist, are in so miserably mutilated and fragmentary a condition, as to suggest, in most instances, the belief that, when broken up for the purpose of being re-used, the originals were already imperfect, and perhaps cast aside as useless. Bruns' palimpsest of Livy contained only a fragment of the ninety-first book; the re-written manuscript of Pliny's *Natural History*, discovered by Mone, has but a small portion of a few of the early books; Pertz's *Granus Licinianus* is but a scrap; and a palimpsest of St Jerome's *Commentary*, mentioned by Mone (*Lateinische und Griechische Messen*, 162), contains parts of no fewer than seven different works. Even the larger and more important palimpsests deciphered by Mai,—the Cicero *De Republica*, the Plautus, and the great palimpsest of the historians,—are all unhappily in such a state of imperfection, as to make it impossible to suppose that the copies of the original authors on which the transcriber laid his hand were other than fragments, already of little value from their defective condition. Some palimpsests, indeed, are made up of miscellaneous fragments from isolated leaves of different writers, seemingly little better than the refuse of some book-shop or library.

But, whatever may have been the condition of the originals which were selected for re-transcription by the mediæval copyists, even the fragments of ancient writing which they have thus been unconsciously instrumental in preserv-

[1] And yet a relic of that time, of equally, or even more perishable material, has been preserved. In the year 1840 two ancient waxen tablets (dating from A.D. 169) were discovered in a state of high preservation—one in a gold mine in the village of Abrudbânyá in Transylvania, the other in the immediate vicinity, with the wax and the characters inscribed upon it almost perfect. They are described by Dr Massmann in a dissertation published at Leipsic in 1841. The tablets are of the triptych form—one of fir, the other of beech. Their form and construction exactly answer to the description of the *tabulæ ceratæ* given by our antiquarians, but the writing upon them runs from right to left, beginning upon what we should call the last page, and ending at the bottom of the third. See also an article by Dr Detlessen in the *Sitzungs-berichte der Kaiserl. Academie der Wissenschaften*, vol. xxiii., pp. 601 and following.

ing are unquestionably of deep interest, and in many cases of great value, for the modern cultivators of ancient learning. With the profound and far-seeing critical sagacity which distinguished him, Montfauçon (*Palæographia Græca*, p. 223) early called attention to the fruits which might be expected from a careful examination of these buried treasures; nor has the exploration (although it has not resulted in the recovery of any *complete* work of antiquity) disappointed his expectations. The labours of the learned in this department have already resulted in many great discoveries, and have given promise of many more. Some invaluable fragments of ancient works, believed to be entirely lost, have already been recovered; and the hopes which may fairly be entertained of future acquisitions from the same source will best be estimated by a short account of what has actually been effected within the present century.

The value of ancient manuscripts has long been rightly appreciated; and hence in every part of Europe they have been collected at great expense, and preserved with the utmost care. For some time after the invention of printing it was indeed thought that, when the contents of a manuscript had been copied, and multiplied by means of that invaluable art, the original was rendered useless. But, as different manuscripts of the same work often vary in particular readings, it was soon found necessary to examine and collate a number of them, in order to ascertain the preferable readings; and without this previous care, conjoined with critical discrimination, a new edition of an ancient work would not now be well received by the learned. Such, then, is the most direct and obvious use of ancient manuscripts; which, when duly collated, furnish the means of restoring texts that had been corrupted or mutilated in the course of frequent transcription.

But, on a more minute examination of a certain class of manuscripts, it appeared that some of them might have a value hitherto unsuspected, by supplying more ancient copies than were previously known, and even furnishing portions of important works which were supposed to be entirely lost. These were manuscripts in which the attempt to obliterate some more ancient writing, in order that the parchment might be again used to receive another work, had been so far ineffectual that traces of the ancient writing still remained discernible, and capable of being partially or entirely deciphered by the patience and ingenuity of literary explorers. Certain manuscripts of respectable antiquity were thus found to conceal others several centuries older, and frequently of much superior interest and value. The number of such manuscripts, or portions of manuscripts, which existed in the several great libraries of Europe must have been very considerable. One of the earliest editions of the *Clementine Constitutions* (1476) was actually printed on palimpsest parchment. Many have been preserved in our own time; and a fresh impulse has been recently given to the zeal of the learned by the interesting discovery, that many of the long-neglected manuscripts of the churches and monasteries of the Levant are of the same palimpsest class. The character and appearance of different palimpsests differ very considerably. In some the ancient writing has been so imperfectly effaced, whether by washing, or by rubbing with pumice-stone or some similar substance, that the more modern writing interferes but little with the distinctness of the original; so that it may be deciphered by a practised eye, or at least can be so far revived by certain simple applications, and by exposure to the light, as to be read with little difficulty. In others, however, in which, besides the sponge and the pumice-stone, the scraping-knife had been freely used, it is only by the use of very powerful chemical agents, which shall be described hereafter, and by the aid of strong lights and lenses of considerable magnifying power, that the contents can be discovered. In some palimpsests the modern scribe has exactly preserved the form of the ancient sheet, and has divided his pages in the same manner; but, more commonly, the new writing exhibits an entire disregard of the order of the original. Sometimes, where the original page was divided into two or three columns, the modern matter is written over them all in one unbroken line; sometimes the original sheet is folded double, or even cut in half; sometimes the page is turned upside down; sometimes the new writing runs diagonally across it; sometimes (most perplexing of all) it follows closely line for line, and even letter for letter, the tracks of the original, so that the characters blend and run into each other, and the distinction between new and old is only discernible from the uncertain test of the different colour of the inks, or of the diversity of the form of the characters. These difficulties are tenfold exaggerated where the characters of the original were minute, and where the modern writing is of the same size and in the same language. We shall see examples hereafter in which the original has been *twice* written upon; and others in which, if we reckon corrections, no fewer than four different writings are found in the same palimpsest.

In the ages which immediately succeeded the invention of printing, the attention of scholars was so engrossed by the numberless manuscripts of ancient authors which abounded in all the great centres of learning, that the hidden stores of palimpsest literature were unobserved or disregarded. But so soon as the first harvest, so to speak, had been gathered in, and men began to prize even the gleanings which had escaped the early labourers, the value of these buried treasures did not long remain unnoticed. It is true that, as has been already observed, all the palimpsests hitherto discovered have been but fragments, and that a large proportion of them consist of works previously known in a much more complete form. But it will be seen, nevertheless, that, even already, several of those which have been deciphered have contributed to fill up a very considerable gap in the lost literature of the ancient world; and even those which contain works already known and published have this important advantage for the purpose of criticism, that they supply copies of these works earlier by several centuries than the very earliest of the original manuscripts of the same works already in existence. The immense importance of this circumstance, especially for the uses of the biblical critic, it is impossible to overrate.

The fruits which may yet be anticipated from the full development of these curious and interesting researches will be best understood from a short history of the successes which have been already obtained. For the sake of clearness, we shall consider—*first*, Sacred palimpsests; and, *secondly*, Palimpsests in profane literature.

Biblical palimpsests.

I. By far the most important relics of the first class are the Biblical Palimpsests.

The first rescribed biblical manuscript of which any important use was made appears to have been *Codex Ephremi*, or *Codex Regius* of Paris. The more modern writing in this manuscript contains certain works of St Ephrem the Syrian, in Greek; the more ancient seems to have contained the whole of the Old and New Testament, in a character and style of Greek writing which Dr Tischendorf of Leipsic assigns to the fifth century. Of this manuscript there are 209 leaves remaining, 145 of which belong to the New Testament, and comprehend nearly two-thirds of the entire text; but the leaves appeared to the first explorers so miserably confused and misplaced, and with so many chasms of various kinds, that sometimes scarcely a word could be deciphered in a whole leaf. Nevertheless, the difficulties occasioned by these defects and mutilations have not deterred critics from endeavouring to make the most of the *Codex Ephremi*. It was first observed and examined by Jean Boivin, from whom Küster obtained several important readings, which he inserted in his reprint of Mill's Greek Testament in 1710;

and Wetstein afterwards, at the instance of Bentley, collated with great diligence all that it contains of the text of the New Testament. Griesbach considers this as the most ancient manuscript collated by Wetstein; and there can be no doubt that the readings thus obtained confer a particular value on his edition. For a long time, however, nothing of real importance was done in the work of deciphering it; but at last, in 1834–5, M. Hase, by the use of a chemical preparation known by the name *tinctura Giobertina*, succeeded in reviving the ancient writing to a degree far beyond the expectation of the first explorers; and in 1840–1 Dr Tischendorf devoted himself to the task of preparing for publication the New Testament fragments, which he finally accomplished in 1843. In 1845 he completed the work by the addition of those fragments of the Old Testament which are contained in the palimpsest. An additional source of the interest and the value which attach to this curious palimpsest is the circumstance that, previously to its being turned to its modern use by the transcriber of St Ephrem in the thirteenth century, the original had undergone three distinct corrections, by different hands and at remote intervals, in the sixth, ninth, and eleventh or twelfth centuries; most of which corrections are still distinctly traceable, and supply an interesting practical commentary on the history of the text.

The next discovery amongst manuscripts of this description was one of a very interesting kind. Ulphilas, bishop of the Goths in the fourth century, is known to have translated the whole Scriptures into the language of that people, who had lapsed into Arianism. For this purpose he invented for them a new character, consisting of letters borrowed chiefly from the Greek. This work, however, had long been lost, with the exception only of the part containing the four Gospels, which is preserved in the University Library at Upsal, in a manuscript called *Codex Argenteus*, from being written chiefly in letters of silver. But in the year 1755, F. A. Knittel, having been appointed archdeacon of Wolfenbüttel, began to explore the treasures contained in the Augustan Library in that city; and in the course of his researches a palimpsest manuscript[1] of the *Origines* of Isidorus of Seville was pointed out to him as containing, under that writing, the translation of the Epistle to the Romans by Ulphilas, together with two other Greek fragments of the Gospels. The first of these (known to biblical critics as the *Codex Guelpherbytanus* A) consisted of forty-three leaves containing parts of each of the four Gospels. It is believed to be of the sixth century, and its readings have been highly valued. The second (called *Codex Guelpherbytanus* B) consisted of thirteen leaves containing parts of St Luke and of St John. It seems to be of the same period with the last. Knittel's interest, however, was principally fixed on the fragment of Ulphilas. On examination, it proved that the manuscript did not contain the whole Epistle to the Romans, but only a portion of the latter part, viz., the eleventh and following chapters, as far as the thirteenth verse of the fifteenth, accompanied by a Latin version written in parallel columns, which is in itself of no slight interest, as it is earlier than the revision of the Vulgate by St Jerome. Knittel immediately set himself to work on this curious fragment; and although, from the state of the leaves to be deciphered, the difficulty of the task was great, yet his zeal carried him through; and towards the end of the year 1758 he announced the intended publication by subscription. Various obstacles, however, retarded its appearance till the year 1762, when the laborious decipherer was enabled to publish the whole in quarto, with twelve large plates, accompanied by an account of the manuscript, and copious illustrations of its contents. The diligence of Knittel omitted nothing that could render useful the recovered fragments both of the two Greek manuscripts and of the Gothic version. The latter, in particular, he carefully compared with the *Codex Argenteus* at Upsal, and ascertained that the Wolfenbüttel palimpsest did not form part of the same, but only of a similar manuscript. From the different fragments he extracted all the various readings. These fragments were reprinted by Busching in 1773, and by Zahn in 1805. But by far the most important contribution to our knowledge of the version was made in 1817 and the following years, by the celebrated Angelo Mai (of whom we shall have occasion to speak more at large under the head of "Classical Palimpsests"), and his friend and fellow-labourer, Count Carlo Castiglione, from five different palimpsests discovered by Mai in the Ambrosian Library at Milan, and containing, under modern transcripts of various authors,—St Gregory the Great, St Jerome, Plautus, Seneca, and the Acts of the Council of Chalcedon,—nearly four hundred pages of fragments of the Gothic version of the Epistles of St Paul, of the Gospel of St Matthew, and some of the books of the Old Testament. All the fragments of this version, from whatever source, were collected into the edition of Gabelentz and Löbe, which appeared in successive parts at Leipsic, from 1836 to 1845; and a complete critical edition has still more recently been published by Dr Massmann (Stuttgart, 1855). The next in the order of time among the biblical palimpsests is that of Dr Barrett of Trinity College, Dublin; an elegant volume (Dublin, 1801), containing a great part of the Gospel of St Matthew, copied from a rescribed manuscript in the library of that college. This palimpsest appears to have been rewritten in the twelfth or thirteenth century upon portions of much more ancient books. The most important of these, however, was the portion which contained the copy of St Matthew's Gospel, whereof this fragment remained, written in uncial letters; and, judging by the usual marks of antiquity, it seems to belong at least to the sixth century. A part of Isaiah in Greek, and some of the Orations of Gregory Nazianzen, were likewise found in it, but were considered as of less moment. What remains of St Matthew's Gospel is printed on sixty-four engraved fac-simile plates, each representing a page of the manuscript, and containing from twenty-one to twenty-three lines, disposed in a single column, with the text in the ordinary Greek character upon the opposite page. This valuable fragment commences with part of the genealogy, at verse 17, chapter i., and extends, with occasional chasms, to chapter xxvi., verse 71; and it is also represented in an equal number of pages printed in the ordinary Greek character. Copious prolegomena are prefixed, giving an exact account of the state and characters of the manuscript; and subjoined is a careful collation of the *Codex Montfortianus*, in the same library, with Wetstein's edition. Unfortunately, however, the text, as printed in the ordinary Greek characters, is by no means a perfectly accurate transcript of the engraved plates; and this circumstance, as well as the defective condition of many of the pages, having created a general desire for the re-examination of the Dublin palimpsest, Dr Tregelles, in 1853, by the aid of active chemical agents devised by more modern manipulators, succeeded in bringing to light "*all* the older writing, hardly even a letter excepted." It is to be regretted, however, that, in the re-binding of the manuscript since its publication by Dr Barrett, some portions of the ancient writings have been lost, through the efforts of the ignorant workman to give an air of neatness to the volume, by *squaring the leaves and paring them to an even edge.*

By far the most important discovery in modern biblical

[1] This manuscript is the celebrated *Codex Carolinus*. Its acquisition by the Wolfenbüttel Library is comparatively recent. But Cardinal Mai (*Classici Auctores*, i. 43) claims it, on the authority of Niebuhr and on intrinsic evidence, as once the property of the monastery of Bobbio, one of the many colonies of the early Irish monks in Italy, Switzerland, Southern Germany, and France.

Palimpsests.

palimpsest literature, is that of the palimpsests comprised in the collection of manuscripts recently collected from the monastic libraries of the Levant, and deposited in the British Museum and the Bibliothêque Imperiale at Paris.

In one of these (known as the *Codex Nitriensis*, from the monastery of St Mary Deipara, in the desert of Nitria, whence it was obtained) Dr Cureton discovered (besides a most valuable fragment of the *Iliad*, of which we shall speak later) forty-five leaves containing fragments of the Gospel of St Luke, over which had been written a Syriac translation of the Monophysite treatise of Severus of Antioch against Grammaticus. The later writing was so heavy and so black, and the erasure of the original had been so successful, that it was exceedingly difficult to decipher it; but it was successfully collated in 1854 by Dr Tregelles, and was prepared by him for publication, had he not been anticipated by Dr Tischendorf in the collection to be described hereafter. These fragments are believed to be of the sixth century, and even of the early part of that century.

Another Syriac manuscript, in the British Museum, examined by him, contains a few palimpsest leaves, which are of extreme antiquity, and the under writing of which consists of fragments of St John's Gospel. The Greek characters resemble very closely those of the well-known *Codex Vaticanus*; and the Greek original of the palimpsest is especially curious, as having been at least *twice* written over in Syriac; so that it belongs to the class (of which we shall see two other examples) of *thrice-written* manuscripts.

No modern biblical editor, indeed, has laboured in the field of palimpsest literature with such perseverance and with such success as Dr Tischendorf. In addition to his re-collations and reprints of almost all the most valuable early editions of the sacred texts, he has, with infinite industry and research, given to the public many most curious and valuable fragments of the Old and New Testaments, collected by himself from palimpsest sources. A few of these are of western origin; but the greater and much more important portion is from the Syriac and Armenian palimpsests of the collection already described. They are for the most part contained in his magnificent publication, *Monumenta Sacra Inedita*, vol. i., 1855, vol. ii., 1857. The first volume is entitled *Fragmenta Sacra Palimpsesta; sive Fragmenta cum Novi tum Veteris Testamenti ex quinque Codicibus Græcis Palimpsestis antiquissimis nuperrimé in Oriente repertis. Addita sunt Fragmenta Psalmorum Papyracea, et Fragmenta Evangelistariorum Palimpsesta; item Fragmentum Codicis Frederico-Augustani, nunc primum eruit atque edidit* Œnoth. Frid. Const. Tischendorf, Lipsiæ, 1855. This most beautiful volume consists of fragments deciphered from seven palimpsests, of which five were brought from the East: one is preserved in the Barberini Library at Rome, and one in the Library of St Mark's at Venice. The first, the modern writing of which is Armenian, contains forty-eight pages of fragments of the New Testament—of the Gospels, of the Acts, and of the Epistles of St Paul to the Corinthians and to Titus. The second, under some Greek lives of saints and a homily of John of Damascus, contains large fragments of the book of Numbers and some portions of Isaiah. The third, in which the modern writing consists of the lives of four saints—Euthymius, Sabas, Abram, and Theodosius—in Arabic, contains fragments of Numbers, Deuteronomy, Joshua, Judges, Kings, and Isaiah; and the fourth and fifth, which were both re-written in Armenian, contain other fragments of the books of Kings. Dr Tischendorf's second volume is entitled *Fragmenta Evangelii Lucæ et Libri Genesis, ex tribus Codd. Græcis, quinti, sexti, octavi sæculi; uno Palimpsesto ex Libya in Musæum Britannicum advecto; altero celeberrimo Cottoniano ex Flammis erepto; tertio ex Oriente nuperrimé Oxonium perlato*, Lipsiæ, 1857. The most important among the contents of this volume are the fragments of St Luke's Gospel, already referred to as discovered by Dr Cureton in the *Codex Nitriensis*. They extend to ninety-five pages. The volume also contains fragments of the Gospel of St John, from a palimpsest, re-written, with some hymns of Severus the Monophysite, in Syriac; a few pages of Ezekiel, also from a Syriac palimpsest; and two pages of the third book of Kings, from a palimpsest partly Coptic and partly Syriac.

Such are the most remarkable contributions to the original text of sacred Scripture from palimpsest sources. These contributions are in all likelihood but an earnest of what may yet be anticipated; but even these are of a value which only scholars who are acquainted with the limited extent of the ancient sources of biblical criticism now available can fully appreciate. Perhaps, out of all the existing manuscripts of the original texts, the *Codex Vaticanus* and the *Codex Alexandrinus* are the only ones which exceed in antiquity some of the precious fragments thus unexpectedly recovered. We need hardly add that, unlike most other originals, every scrap of the sacred text, however minute, possesses a value of its own, entirely independent of the context or connection; and, therefore, that no fragment, however minute or however mutilated, can be overlooked by a biblical critic who is animated by the true spirit of his craft.

Of the other sacred palimpsests which have been as yet made public, the most important are a series of fragments of the early liturgies, both of the Greek and of the Latin churches, discovered in the library at Karlsruhe, in a manuscript re-written with St Jerome's *Commentary on the Gospel of St Matthew*. These interesting remains were published (with a fac-simile) by Francis Joseph Mone at Frankfort in 1850 (*Lateinische und Griechische Messen, aus dem zweiten bis sechsten Jahrhundert*). Many other fragments of the same character—liturgies, sacramentaries, rituals, canons, homilies, &c.—are known to exist. A few of them have been published by the same editor and by Cardinal Mai; and much information on the obscure but important subject of the early liturgies may be expected from a complete and careful examination and comparison of them all.

Classical palimpsests &c.

II. In ancient profane literature the additions from palimpsest sources have been much more numerous and considerable, consisting of large fragments of lost Greek and Roman classics, and of the text, and commentaries on the text, of ancient Roman law.

Bruns.

The first editor of a palimpsest relic of classical literature was Paul James Bruns, the coadjutor of Dr Kennicott in his great work of Hebrew collation. In 1773 Bruns discovered at Rome a fragment of the ninety-first book of Livy, in a rescribed manuscript of the Vatican collection; and in the same year it was published by the discoverer himself at Hamburg, and by Signor Giovenazzi at Rome. The fragment in question, which has been admitted as undoubtedly genuine into the later editions of Livy, contains part of the war with Sertorius in Spain; and the only subject of regret is, that this part is so small. Bruns first visited the Vatican on a mission from Dr Kennicott in reference to Hebrew collation; but having been thus fortunate in the investigation of a palimpsest, he renewed the inquiry in this country, and endeavoured to ascertain the number of such manuscripts in the Bodleian Library at Oxford. An account of his researches will be found in the *Literary Annals of Helmstädt*, which appear to have been conducted by Bruns during the years 1782, 1783, and 1784. A small portion of the ninety-first book of Livy, which Bruns failed in reading from the manuscript, was afterwards successfully deciphered by Niebuhr, who also supplied some other deficiencies, and published the entire book, together with another Ciceronian fragment, at Berlin in 1820.

Mai.

It remained, however, for another distinguished labourer in the new and interesting field of inquiry which had thus been indicated rather than explored, to surpass all his pre-

decessors and contemporaries, not only in discovering rescribed manuscripts, but also in extracting from them works or parts of works which were long considered as irrecoverably lost. We allude, of course, to the Abate Angelo Mai, doctor of the Ambrosian Library at Milan, afterwards first keeper of the Vatican, and finally (1838) cardinal librarian of the Roman Church, whose researches in this department were so extensive and important that he may truly be called the hero of palimpsests, and the discoverer of a new world of letters. (See MAI.) It was not till the year 1814 that Monsignore Mai made himself known by the partial discovery of lost works. A year earlier, indeed, he had employed himself in translating a large portion of the oration of Isocrates *De Permutatione*, which Mystoxides, a learned Greek, had published from a manuscript in the Ambrosian Library more perfect than any of the codices which had been followed by the editors of Isocrates. The quantity thus inserted in the oration increased it by at least one-half; and the same additional matter has since been found in some of the Vatican manuscripts. In publishing this translation, however, Mai modestly continued anonymous. But his name was destined soon to be illustrated by far more important labours.

1. His researches amongst palimpsest manuscripts commenced with certain hitherto unpublished fragments of three orations of Cicero, namely, those for Scaurus, Tullius, and Flaccus. These orations had been written in a quarto form, but had been partly erased and folded into an octavo size to give place to the sacred poetry of Sedulius. The newer writing was judged to be as old as the eighth century, and the original to be not later than the second or third. The manuscript had belonged to a very ancient monastery at Bobium, or Bobbio, in the Milanese, founded by St Columban, who had also formed its library; and in the collection obtained from the same venerable institution the greatest part of the rescribed manuscripts has been discovered. "In examining carefully some manuscripts in the Ambrosian Library at Milan," says Mai in his preface, "I observed that one of great antiquity was a palimpsest. This manuscript had belonged to the convent of Bobbio, a monastery in Liguria, situated in the midst of the Apennines, which was founded by St Columban in the year 612, and the monks of which obtained considerable reputation for learning as well as sanctity. Gerbert, a Frenchman by birth, who became pope under the name of Silvester II., and attained so much celebrity for learning that he is one of those who, in the rude popular tale, are reported to have sold their souls to the devil, was head of this monastery in the tenth century, and added greatly to the reputation of the place, as well as to the contents of the library. The Cardinal Frederigo Borromeo, who founded the Ambrosian Library at the beginning of the seventeenth century, purchased the principal part of the collection at Bobbio and brought it to Milan. Whilst I was examining these manuscripts," he adds, "I remarked that one, which contained some of the writings of Sedulius, a Christian poet, was a palimpsest; and on looking very closely and attentively I discovered traces of the former writing under the latter." He then read the titles, *pro Scauro*, *pro Tullio*, and *pro Flacco*, and was able, with some trouble, to decipher the whole of the fragments of these three lost orations, written in large and very beautiful characters, each page being divided into three columns. The oration for Scaurus was accompanied by *scholia*, elegantly written in small letters of a square form; and there were others in characters of a ruder form, but still ancient. These three fragments, together with the scholia (which Mai considers the production of Asconius Pedianus), were published at Milan, 1814, in one volume 8vo.

2. In the course of the same year Monsignore Mai produced a second volume, containing various fragments of three other orations of Cicero, with some ancient annotations and commentaries never before published. The portions thus recovered belonged to the orations against Clodius and Curio; to that *De Ære alieno Milonis;* and to the oration *De Rege Ptolemæo*. Of the oration *De Ære alieno Milonis* no other fragment was known until this discovery. These treasures had lain concealed under a Latin translation of the Acts of the Council of Chalcedon, and were adjudged by the discoverer to belong to the fourth century. The palimpsest from which they were discovered had formed part of the collection obtained from Bobbio. The older writing was in very large and handsome characters, but less beautiful than that which contained the fragments of the three orations mentioned in the preceding paragraph; and there were only two columns in each page, a circumstance which seems to indicate that the writing is somewhat less ancient. The contents of these two volumes the learned editor afterwards united into one, which he published in 1817, with corrections of the fragments that had first appeared, and some additional notes and illustrations. The great antiquity of the practice of rescription is sufficiently attested by these various fragments of Cicero's orations; indeed it is supposed that the speech for Scaurus was obliterated in the eighth century. But Latin manuscripts appear to have been more frequently subjected to this treatment than Greek manuscripts, or those in any other language. It is true, that in the "Collection of Greek Papyri from the British Museum," there is an ancient palimpsest papyrus, in which the original was the enchorial Egyptian, and the second writing is Greek. But this is a very rare instance; and even of this papyrus, it would be difficult to show that the date of the second writing is earlier than that assigned to the earliest Latin palimpsests.

3. The year 1815 proved very rich in discovery, and gave birth to no fewer than three volumes of unpublished works. One of these is peculiarly valuable and curious, as containing large portions of several orations of Symmachus, in whom, as Mai expresses it, breathed the last inspiration of Roman eloquence. The epistles of this famous orator were the only productions of his pen previously extant; but in these recovered fragments we have a copious specimen of his eloquence in two panegyrics on Valentinian, one on Gratian, a gratulation addressed to the father of the orator on his being appointed consul, and parts of several other works of the same kind, making eight in all. Mai likewise deciphered a portion of a panegyric of the younger Pliny which was contained in the same palimpsest, but of which only the various readings are here given. The original manuscript is supposed to have belonged to the seventh or eighth century. These interesting fragments were reprinted at Frankfort in 1816 in one vol. 8vo.

4. The same year another very ancient palimpsest was found in the Ambrosian Library, containing all the comedies of Plautus which have reached us, except four; and a fragment of the *Vidularia*, a lost comedy, of which all that previously remained consisted of about twenty lines, preserved by Priscian and Nonius. The ancient writing in this manuscript is exceedingly beautiful, and is supposed to be of the time of the Antonines; the more modern, consisting of part of the Old Testament in Latin, is conjectured to be of the seventh century. Mai deciphered a number of various readings, together with about sixty inedited lines belonging to the different comedies; and restored the following spirited lines of the *Stichus* (act i., sc. 5), which had previously existed in an imperfect state:—

> "Famem fuisse suspicor matrem mihi,
> Nam postquam natus sum, satur nunquam fui;
> Neque quisquam melius referet matri gratiam,
> Quam ego matri meæ retuli invitissimus."

This, therefore, is an important discovery, not so much on

account of what has actually been recovered, as by reason of the expectations which it is calculated to encourage. For if Monsignore Mai found a Latin Bible containing almost an entire copy of Plautus, it cannot be affirmed that any classical author is irrecoverably lost until every Bible in manuscript, and every other writing upon ancient parchment, has been diligently examined. There is no moment at which some important discovery may not be made, provided the labour of scrutinizing parchments be persevered in. That there are many palimpsests in the public libraries of Great Britain, particularly in the Bodleian at Oxford, which is singularly rich in manuscripts, can scarcely admit of a doubt. The number of manuscripts in Spain, and her vast mass of archives, have long been equally famous; nor is it impossible that several lost works, or portions of works, by Latin authors, may yet be found in that country. Although the search for manuscripts that are directly and obviously valuable may have proved fruitless, yet a very different result may follow when parchments are examined with a view to ascertain whether a lower stratum of writing exists beneath the sterile surface, and whether some of the most precious remains of ancient genius and eloquence may not be covered or concealed by the rubbish of chroniclers and ecclesiastical writers. It is true that much has perished irrecoverably. In the Protestant parts of Europe the most frightful havoc was committed at the Reformation. Huge volumes containing the ancient services abounded in all the churches and monasteries. Most of these had been brought directly from Rome; and in the days when books of this kind were transcribed, it may, by some, have been considered an act of piety to erase profane writings, especially if imperfect, in order to make way for the sacred offices. From the very nature of these books, indeed, there can be little doubt that much *ancient* parchment entered into their formation; and as they were carefully preserved, exempt from accident or injury, there can be little doubt that in many, perhaps in most of them, there existed under the rescription the remains of more ancient writings. Wherever they could be found they were consigned to the flames without mercy, in virtue of enactments which enjoined the destruction of all popish books; and inestimable chances of discovery were thus for ever lost to the world. But great as was the destruction which took place at the Reformation, enough still remains to warrant the conviction, that were there more Mais to examine and decipher palimpsest manuscripts, there would be numerous additional and most important discoveries. Who knows but that, in the most paltry and unpromising volume, may be found the works of the most eloquent of historians?—that

Pellibus exiguis arctatur Livius ingens?

5. The next discovery effected by Mai, from a manuscript of the same class, was that of the remains of the orator Fronto, who had flourished in the reign of Hadrian. This writer, though by birth an African, was in his day esteemed almost a second Cicero; yet of his writings little more remained than a few scattered sentences, preserved in the works of other authors. Mai, however, by his acuteness and perseverance, was enabled to recover a very considerable portion of Fronto's works, which he published at Milan in 1815, in 2 vols. 8vo, under the title of *M. Cornelii Frontonis Opera inedita, cum Epistolis item ineditis Antonii Pii, M. Aurelii, L. Veri et Appiani, necnon aliorum Veterum Fragmentis.* The contents of the first volume consist of one book of epistles addressed to Antoninus Pius, two books to Marcus Aurelius, and two to Lucius Verus; two books of letters to friends; several letters addressed to Marcus Aurelius, on the subject of the *Feriæ* at Alsium, a town in Etruria; and one to Lucius Verus, in which the orator laments the death of his grandson, one of the children of his son-in-law Victorinus. The second volume exhibits a considerable portion of two books, *De Orationibus*, addressed by Fronto to Marcus Aurelius; parts of various orations and epistles; and also a portion of an address to Antoninus, entitled *De Bello Parthico*, consoling him for the reverses experienced in the Parthian war. Then follow some important fragments under the title of *Principia Historiæ;* a few playful prolusions on lighter subjects; and a book of epistles written in Greek. The work is concluded with a collection of all the fragments of Fronto's works which have elsewhere been preserved, and with copious illustrations of those which were then for the first time published. In the palimpsest from which these curious remains were deciphered the more recent writing formed part of the Council of Chalcedon; but the manuscript was unhappily much damaged, and altogether in a very imperfect state. Fronto was a voluminous writer, and composed works upon various subjects, amongst which was an Invective against the Christians. He had a great reputation as an orator, and was accounted the Cicero of his time, although his style, which is said to have united the *siccum* and the *grave*, does not very well accord with such a distinction. The writings of so remarkable a person would, in any circumstances, be an object of interest; but they become doubly curious from having been thus marvellously brought to light.

6. In the meanwhile, Mai was preparing another publication of similar origin, which, in 1816, he gave to the world under the following title, viz., *Interpretes Veteres Virgilii Maronis; Asper, Cornutus, Haterianus, Longus, Nisus, Probus, Scaurus, Sulpicius, et anonymus; e Veronensi Palimpsesto;* and about the same time he discovered the palimpsest of the Gothic Bible of Ulphilas, his edition of which has been already described among the biblical palimpsests.

7. Mai now entered upon a more enlarged and important scene of action. His distinguished merit in this new field of discovery having obtained for him the notice of Pius VII., he was by that pontiff appointed keeper of the Vatican Library, and speedily justified this preferment by a discovery more interesting and valuable than any which he had hitherto made. In a palimpsest volume, which had formed part of the manuscript collection originally brought from Bobbio, and which contained, in the exterior writing, part of the commentary of St Augustin on the Psalms, he found that the interior or more ancient writing had consisted of the long-lost books of Cicero *De Republica*, the most celebrated of all his works, and of which nothing had been known, in modern times, beyond the fragments preserved in the writings of Macrobius, Lactantius, Augustin, Nonius, and others. This precious volume had been purchased by Paul V. more than two centuries before, with the knowledge that it was a palimpsest, and that it contained part of Cicero's treatise *De Republica*, though, by some strange neglect, it was reserved for Mai to bring its contents to light. It was still in excellent order; the characters were large and plain; and in the leaves which remained there was scarcely a page that could not be deciphered; but many of the pages were wanting; and there seemed reason to apprehend that the same deficiency would often occur in future discoveries, because the work last inscribed might not have been co-extensive with the original writing obliterated, and because, when the volume had been taken to pieces for the purpose of rescription, the whole of the leaves that contained the original writing might not have been put together again, but some of them applied to other purposes, and leaves taken from other works, or of new parchment, inserted in their place. But however this may be, in these invaluable pages a very considerable part of the first and second books of the celebrated treatise in question was found so perfect as to be completely recovered by the labour and sagacity

of Monsignore Mai. The portions of the work thus rescued from oblivion were published at Rome in 1821, with copious notes and illustrations, particularly an accurate account of the various chasms occasioned by the loss of original leaves, and accompanied with such a restoration of the four remaining books as could be effected from the less perfect portions of the manuscript, and the various fragments preserved by Sigonius and other critics. A finer specimen of editorial skill, learning, and sagacity is nowhere to be found.

The part of this important treatise which has thus been unexpectedly brought to light, is amply sufficient to give a clear insight into the plan and style of the dialogues, as well as into the characters of the various interlocutors under whose names the illustrious author chose to develop his own opinions. These were, the second Scipio Africanus, and his friend Lælius; L. Furius Philus; M. Manilius, whom Cicero elsewhere praises for his knowledge of the law; Sp. Mummius, the brother of Mummius Achaicus; Q. Elius Tubero; P. Rutilius Rufus; Q. Mucius Scævola; and C. Fannius, son-in-law of Lælius. The introduction to the first book is nearly complete; but that which stamps the highest value on the work is the luminous philosophy of the author on the subject of government and policy, as expounded by Scipio, the principal interlocutor, with unrivalled eloquence and felicity of expression. We now understand the grounds upon which the ancients preferred this to all Cicero's philosophical works; and on the whole, notwithstanding its still imperfect state, it is unquestionably one of the most interesting acquisitions that have been made in the department of classical literature since the original publication of the ancient authors soon after the revival of letters. May we not indulge the hope that eventually other important additions will be made to the invaluable fragment which Mai so laboriously and skilfully brought to light?

8. The zeal and the industry of Mai did not relax from success. On the contrary, soon after the appearance of the fragment of Cicero's treatise *De Republica*, he gave to the learned world another elaborate publication, containing, —1. Juris Civilis Antejustinianei Reliquia inedita; 2. Symmachi Orationum partes; 3. C. Julii Victoris Ars Rhetorica; and, 4. L. Cæcilii Minutiani Apulei Fragmenta de Orthographia. These remains were also recovered from a rescribed manuscript in the Vatican Library, and were, as usual, accompanied by notes, appendices, and illustrative plates.

9. But a much more valuable and generally interesting discovery awaited him. Students of Roman history have long deplored the miserably imperfect condition in which almost all its writers, native and foreign, have come down to our time. Of the works of the Greek writers upon Roman affairs,—Polybius, Diodorus Siculus, Dionysius of Halicarnassus, Appian, Dion Cassius, Iamblichus, and the writers of the later empire, Dexippus, Eunapius, Menander of Byzantium, &c.,—but a very small portion has been saved, and even that in far from a satisfactory condition, whether as to completeness or as to correctness of text. Now, by a rare literary favour of fortune, Mai was enabled, in one single publication, to restore to the world large extracts of each and all these historians, which, both in extent and in historical importance, far exceed all the contributions to their respective texts which, up to this day, had been made since their first publication in the fifteenth and sixteenth centuries. The original of the palimpsest in which these precious fragments lay buried was a sort of commonplace-book, which had been compiled by the order of the learned Emperor Constantine Porphyrogenitus, and in part, indeed, designed and executed by himself. It consisted of extracts from the most eminent authors, arranged under different *τίτλοι*, or heads, originally fifty-three in number. Of these fifty-three heads, however, only two were known before Mai's discovery. Every trace of the rest, with the exception of the names of twenty-two, had been lost; and the variety and the value of the selections from the ancient writers which they must have contained are best estimated from the portions which have been recovered. The palimpsest thus brought to light by Mai contained the title Πέρι Γνώμων, *De Sententiis;* and although, like every other palimpsest as yet discovered, very far from perfect, it comprised a large number of extracts from the lost books of the historians enumerated above. Of the thirty-five lost books of Polybius, for instance (out of forty of which his History originally consisted), the palimpsest supplies copious extracts from all but the last,—from the sixth to the thirty-ninth inclusively,—amounting, in the whole, to 100 quarto pages. The gaps in the *Historical Library* of Diodorus Siculus, of which twenty-six books out of forty have perished, are no less happily supplied. The extracts in the palimpsest commence with the sixth, and extend to the fortieth; making, in the whole, above 130 pages. Nine of the twenty books of the *Roman Antiquities* of Dionysius of Halicarnassus have perished. The Vatican palimpsest contained extracts from them all, to the extent of 64 quarto pages. The fragments of Dion Cassius recovered from the palimpsest are far from filling up the lamentable hiatus in his vast but sadly-mutilated History; but they are by much the most important and most considerable that had hitherto come to light; and they fill no fewer than 100 pages. The recoveries from the other historians are less considerable; but, even in themselves, they are of great value, although, in contrast with the superior extent and importance of the fragments named above, they will be comparatively overlooked. In one word, the appearance of this "Historical Palimpsest" of Mai, as it has been styled, may be regarded as an epoch in the search for the lost literature of Greece and Rome. It appeared, not as an independent work, but as one of the volumes of a vast collection of works in every department of ancient literature, sacred and profane, collected from the unpublished manuscripts of the vast store-house of the Vatican, filling ten immense quarto volumes, and entitled *Scriptorum veterum Nova Collectio*, 1831–8. The "Historical Palimpsest" was Mai's last great work in that line. Each of the three great collections which he subsequently published,—the *Classici Auctores ex Codicibus Vaticanis editi*, 10 vols. 8vo, 1828–38; the *Spicilegium Romanum*, 10 vols. 8vo, 1839–44; and the *Nova Patrum Bibliotheca*, vols. i.–vi.;—contains some interesting fruits of his old spirit of research,—fragments of Lucan, of Juvenal, of Persius, of Gargilius Martialis, and of Aristotle; but their materials are almost exclusively drawn from the unpublished manuscripts of the Vatican.

Niebuhr.

Long, however, before Mai had withdrawn from the work of palimpsest exploration, another labourer of high qualifications, who has been incidentally named already, Niebuhr, had entered the same field of inquiry. The library of the Chapter of Verona had long been famous for the number of the manuscripts contained in it; and it was also known to be remarkably rich in those which related to jurisprudence. In the *Verona Illustrata* of Maffei, published in 1732, the author had given an index to all the manuscripts, and particularly mentioned several leaves of parchment, some of which treated of prescriptions and interdicts, whilst others contained fragments of the Pandects and part of the work of an ancient jurisconsult; "quai codici, se si fossero conservati, niente si ha in tal genere, che lor si potesse paragonare." The leaves in question were afterwards bound up in a small volume, composed of fragments of different manuscripts; and extracts from both were published by Maffei, with a fac-simile of the characters, in his *Istoria Teologica.* But these curious relics attracted little attention, or rather were altogether forgotten, until the successful researches of

Mai had awakened and animated the curiosity of the learned. In the year 1816, Haubold revived the recollection of them by printing at Leipzig a treatise entitled *Notitia Fragmenti Veronensis de Interdictis*, which appears to have attracted considerable notice. In the same year Niebuhr, passing through Verona on his way to Rome, as Prussian envoy to the court of the Vatican, visited the Library of the Chapter, and, during two days which he passed at Verona, took an accurate copy of the fragment *De Præscriptionibus et Interdictis*, and also transcribed another, *De Jure Fisci*. But if this had been all, the labours of these two days, however meritorious, would perhaps have soon been forgotten. Fortunately for letters, however, he examined another manuscript, then numbered xiii., and found that the exterior writing contained some epistles of St Jerome, whilst a more ancient writing appeared underneath. On further examination, Niebuhr perceived that the latter contained the work of some ancient jurisconsult; and having applied the infusion of galls to folio 97, he so far restored the characters as to be able to transcribe the portion of the original text therein contained. He then communicated his discovery to Savigny, and with the assistance of the latter, published in a periodical work the specimen transcribed, accompanied with an ingenious commentary, in which he maintained that the manuscript referred to contained the Institutions of Gaius, the great Roman jurist, probably, under Marcus Aurelius, whose person and history have furnished such a theme for speculation to writers upon Roman law; and that the fragment *De Præscriptionibus et Interdictis* formed part of that work.

The result fully established the soundness of this conclusion. Two other labourers were therefore sent by the Berlin Academy of Sciences to work the mine which Niebuhr had thus happily opened; and, having obtained the permission of the Chapter, they transcribed the manuscript almost entirely, only about one-ninth part of the whole, or rather less, being found illegible. The transcript was immediately submitted to the Academy, and the Institutions of Gaius first appeared at Berlin in the year 1820. The manuscript from which this invaluable relic of ancient jurisprudence was recovered consists of 127 leaves, which have been *thrice* written upon. The more recent writing, which is in uncial characters and of considerable antiquity, contains some of the works of St Jerome, chiefly his epistles, of which there are twenty-six. The more ancient is of two kinds; the one remarkable for its antiquity and elegance, and the other intermediate,—that is, written *over* the first and *under* the third or last writing. The former of these is that in which the Institutions of Gaius were written; so that the intermediate kind had superseded the work of the Roman jurisconsult, but had, in its turn, yielded to the third and last writing. As to the age of the original manuscript, Niebuhr very early expressed an opinion that it was older than the time of Justinian; and Kopp, judging from the forms of the letters, the contractions, and various other indications, arrived at the same conclusion. It is creditable to the literary curiosity of Germany that the first edition of this work was almost immediately sold off. Blume, who had been concerned in the first transcription, paid another visit to Verona, where he re-examined the manuscript with great care; and the fruits of his labour appeared in the second edition, which was published in 1824. In the following year a third edition appeared at Leipzig, without the notes of Göschen, and with the modern instead of the ancient orthography, which had been religiously retained in the two Berlin editions. Gaius was somewhat late in attracting attention in France, where learned lawyers were once so abundant; but the translation of M. Boulet had the effect of partially awakening the curiosity of his countrymen, by rendering this invaluable relic of Roman jurisprudence more easily and generally accessible.

Niebuhr's contribution to Roman Law was followed up by Peyron, who, from a palimpsest of the Turin Library, published in 1824, *Codicis Theodosiani Fragmenta Inedita*, 4to, by Drs Pertz and Gaupp, who printed a portion of the Digest of Justinian, from a Neapolitan palimpsest, at Breslau in 1823.

Palimpsests recently discovered.

The reader will be more interested, however, in the history of the classical palimpsests. Dr Fridegar Mone, son of the well-known scholar of that name already alluded to, discovered, during the year 1854, in a Benedictine monastery in Carinthia, a manuscript of St Jerome's Commentary on Ecclesiasticus, the under writing of which consisted of portions of the first, eleventh, twelfth, thirteenth, and fifteenth books of Pliny. The original is exceedingly ancient. Dr Mone even ascribes it to the second century, and it was not without the utmost difficulty that he was enabled to decipher it. As Pliny's *Natural History* has come down to us entire, the recovery of these fragments is less important than would be a similar discovery of a lost classic, but their value nevertheless will be fully acknowledged by every critical scholar who is aware of the very obscure and seemingly corrupt condition of Pliny's text; and who recollects the light which has been thrown upon the last six books by the new readings from the Bamberg manuscript which Sillig gave in the last volume of his edition of 1831–6. Dr Mone has printed his Carinthian palimpsest in a type nearly fac-simile. (*C. Plinii Secundi Naturæ Historiarum Lib. I., XI., XII., XIII., XV., Fragmenta*, edidit Fridegarius Mone, D.Ph., 1855.)

The oriental collection, to the palimpsests of which biblical criticism has been, as we said, so largely indebted, has also afforded some important contributions to classical literature.

In the *Codex Nitriensis* already described, in addition to the fragments of St Luke deciphered and published by Dr Tischendorf, there was also discovered, under the same Syriac treatise of Severus of Antioch, a second palimpsest, containing large fragments of the *Iliad* of Homer. The original *Codex Nitriensis* was one of a collection of Syriac and other oriental manuscripts purchased for the British Museum from M. Pacho. When first examined, it was found to be defective; but fortunately the missing leaves were discovered in a second collection brought from the east by Dr Tattam; and the *Codex* now contains twenty-three quires (of five leaves each), twelve of which are occupied with the Homeric palimpsest. The whole has been carefully deciphered by Dr Cureton, and published in fac-simile, at the expense of the trustees of the British Museum, in a beautiful volume, entitled *Fragments of the Iliad of Homer, from a Syriac Palimpsest*, edited by W. C. Cureton, M.A., London, 1857. These fragments comprise in all 3873 lines; and although all their contents were previously known, yet their high critical value will be best understood from the circumstance, that the original from which they are printed is more ancient by several centuries than the oldest known manuscripts of the *Iliad*—than the celebrated "Townley Homer," than the "Bankes Papyrus," than the papyrus now in the possession of Mr Harris at Alexandria, and the Ambrosian palimpsest discovered by Mai. As a specimen of palimpsest typography, the book is one of the most beautiful hitherto produced.

Another, and still more curious fruit of the Syriac palimpsests, and the last[1] which we have to record, was published a few months since at Berlin, from a codex in the

[1] Some slight fragments of Lucan, Seneca, Aulus Gellius, and Hyginus the fabulist, deciphered by Niebuhr; of the *Phaëton* of Euripides, published by Hermann (Leipsic, 1821); of Sallust, Pliny, and Lucan, discovered by Pertz; and a few minor scraps, might also be mentioned; but they do not require any detailed notice.

same collection of the British Museum—*Gai Grani Liciniani Annalium quæ supersunt, ex codice ter scripto Musæi Britannici Londinensis, nunc primum edidit Karolus Augustus Fridericus Pertz, Ph.Dr.*, Berolini, 1857. The palimpsest was first observed, and in part transcribed, by the father of Dr Pertz, the well-known historian and antiquary of that name; but it was not till the year 1856 that the younger Pertz completed the transcript, which appears to have been a task of exceeding difficulty. The codex, as will be collected from Dr Pertz's title, is a *thrice-written* manuscript; and it differs from the similar palimpsest of the Institutions of Gaius in having its outermost or most recent writing in the Syriac language, and in the most difficult and complex form of the Syriac characters—the cursive letters. The second writing is in Latin, and contains portions of the work of some unknown grammarian (the chapters *De Verbo* and *De Adverbio*), of whom we only learn that he flourished between the second and fifth centuries of our era. The lowest and earliest writing is in large uncial characters, and contains portions of five books of the Roman history of an annalist called Gaius Granus Licinianus, who is named by Macrobius and by the commentator on Virgil Servius, but of whom nothing else is known. The recovered fragments present intrinsic evidence of having been written after the History of Sallust and before that of Livy: they are from the twenty-sixth, twenty-eighth, thirty-third, thirty-fifth, and thirty-sixth books; and they regard a period of great interest, A.U.C. 509–676. The least incomplete chapters are those which regard the Cimbrian war, the civil war, and the Mithridatic war; but it must be owned that the recovered fragments throw little new light even upon these events. This recovery, nevertheless, is very interesting, both for itself and for the hope which it seems to hold out, that in other quarters which yet remain to be explored, and which at present seem to promise as little for ancient western literature as the long-forgotten monasteries of the Levant, we may yet disinter, from some thrice, or even more frequently re-written codex, the most precious of the long-lost treasures of antiquity.

The general appearance and characteristics of palimpsests will best be understood from inspection. There are few of the great libraries which do not possess at least a specimen or two; and even from the fac-similes which accompany most of the palimpsest publications, a very good idea of the original may be formed, especially from those of the Cureton palimpsest of the *Iliad*, those of Tischendorf, and the small plate of Pertz. In most cases, however, the palimpsest is represented, not in its original form, but in that which it presents after it has been chemically treated for the purpose of being deciphered. Cardinal Mai, in some of his plates, represents both appearances.

The method of manipulating palimpsests, for the purpose of deciphering the ancient writing, depends partly on the condition of the manuscript, partly on the ink in which the original was written. In some, indeed, the ancient writing is quite readily deciphered without any preparatory process whatever; in others, on the contrary, the original is found to have been so carefully and so successfully effaced, that no amount of skill or perseverance will avail to the complete decipherment of their contents.

To comprehend the process of restoration, it must be understood that there were two methods employed by the ancients in effacing the original writing—the wet and the dry. The first consisted in moistening the surface of the parchment, washing it with a sponge, and rubbing it down with pumice-stone. Of the second there were two different forms; either the entire line was scraped away with a broad scraping tool or blade, or the operator followed the course of each separate letter, and obliterated each in succession with the point of the tool. The ink, again, was of three kinds—metallic (which was that commonly used), vegetable, and animal; and as the action of the ink, whatever may have been its composition, was not confined to the surface, it is found that, even after the superficial trace of colour has been partially or entirely removed, its unobserved presence may still be detected by careful scientific treatment.

The first method, and one frequently adopted by Mai, is simply to wash the page with an infusion of galls, and expose it for a time to the action of light and air. This application, in Mai's hands, was in many cases sufficient to restore the buried writing so far that, in good clear light, it could be deciphered by any practised palæographer.

In other cases, however, the effect of this treatment is to blacken the parchment, and to render both the old writing and the later entirely illegible. M. Peyron of Turin, the editor of the fragments of the Theodosian Code described above, having experienced this effect, adopted a prescription suggested by his colleague Giobert, professor of chemistry in the same university. The parchment is first carefully washed in common water; it is then dipped in diluted muriatic acid, and finally in prussiate of potash. This treatment, which had already been suggested by Blagden in the *Philosophical Transactions* for 1787, proved entirely successful; and a preparation founded on it is now known by the name *tinctura Giobertina*. Dr Pertz, in the effort to decipher his palimpsest of Granus Licinianus, was struck by the singular circumstance, that the same mode of treatment *did not succeed equally with both sides of the parchment.* The chemical agent employed by him was a preparation of sulphuretted ammonia—(his formula is, N^2H^5S, aqua × –), which he found perfectly successful in reviving the characters *upon the outer surface of the skin*, as this surface, from its hardness and the closeness of its grain, had been but little defaced by the process of rubbing. But the inside of the skin, being softer and looser in texture, and therefore having been impressed to a greater depth by the process, remained almost entirely unaffected by this application. For the inside of the parchment, therefore, Dr Pertz found it necessary to have recourse to the agent already referred to,—the *tinctura Giobertina*,—for which he gives two different formulas,—*cfy* + 2K, and CyK + CyFe. In deciphering the fragment of Livy, which he published from a Berlin palimpsest (Berlin, 1848), Dr Pertz used a mixture of the ordinary preparation of sulphuretted ammonia and the *tinctura Giobertina* in equal parts.

Where the ink of the original is a vegetable product (as in the case of a palimpsest of the Gallican Psaltery described by Mone, p. 40), the palæographers have failed to restore the original writing sufficiently for the purpose of being deciphered. For inks which contain animal substances (as milk or the blood of the cuttle-fish, the μέλαν of the ancients), Dr Mone directs that the manuscripts be placed in a close vessel filled with oil, and heated to 400° R.

Much, however, it need hardly be added, will depend on the experience and judgment of the manipulator. Many useful suggestions will be found in the prefaces of Mai and other editors, and especially in F. J. Mone's *Lateinische und Griechische Messen;* Pertz's *Gai Grani Liciniani Annalium quæ supersunt;* and Fridegar Mone's *De Libris Palimpsestis, tam Latinis quam Græcis*, Karlsruhe, 1855. (C. W. R.)

PALINDROMUS, or PALINDROME (πάλιν, *again*, and δρόμος, *a course*), a verse or sentence which runs the same when read either backwards or forwards. Such is the verse,

Roma tibi subito motibus ibit amor.

Some people have refined upon the palindrome, and com-

Palinode || Palissy.

posed verses, each word of which is the same read backwards as forwards; for instance, that of Camden :—

Odo tenet mulum, madidam mappam tenet Anna.
Anna tenet mappam madidam, mulum tenet Odo.

PALINODE (πάλιν, *back*, and ὁδός, *a way*), a discourse contrary to principles formerly avowed; and hence the phrase *palinodiam canere* means a recantation. (Macr. *Saturnalia*, vii. 5.) The term is properly applied to a piece in which a poet retracts the invective of a former satire.

PALINURUS, or PALINURI PROMONTORIUM (*Capo Palinuro*), was a mountainous headland on the coast of Lucania, between Velia and Buxentum. It derived its celebrity, as well as its name, from Palinurus, the pilot of Æneas, who, according to Virgil and other Latin authors, was cast ashore and buried near the promontory. It was also well known for its well-sheltered haven, which still bears the name of *Porto di Palinuro*.

PALISSY, BERNARD, commonly called "The Potter," was born about 1509, in the diocese of Agen in France, or, according to some, at Chapelle Biron, a poor hamlet near the small town of Biron in Perigord. His father is said to have been a glass-worker, who exercised his craft, like the rest of his fraternity in those days, in the recesses of a forest. Young Bernard's education was accordingly sadly neglected; but, "as a child, he rolled upon the moss, and ripened with the chestnuts," which, in the long run, proved not quite so bad a school for the youth as might have been supposed. With some skill as a worker in painted glass, he, at the age of eighteen, set out to study nature, to see the world, and to earn his bread. The succeeding nine or ten years of his life were spent in wandering over France in all directions; painting a window now and then; constantly prying into the secrets of nature in woods and fields, by rivers and roads; talking with a wise man when he found one; studying his Bible as he went, and eagerly reading what scraps of philosophy came in his way. It was during these journeyings that he first became acquainted with the Reformed doctrines, which he subsequently espoused, and for which he had ultimately to suffer. In 1538 Palissy took up his abode in the little town of Saintes, married, and gave up wandering. During these years his eye chanced to light upon a beautiful enamelled cup of Italian manufacture, when, without the slightest knowledge of the art, he too resolved to make enamels as well as any Italian. He set about his experiments with uncommon ardour; but nothing came of it meanwhile, he says, but "great cost, loss of time, confusion and sorrow." His attention was diverted for a time by the duties of surveyor of the salt-marshes of Saintonge, to which he had been appointed; but the discovery of white enamel again became his care. Failure upon failure mocked his enthusiasm: his neighbours jeered him, his wife became petulant, and his children clamoured for bread. Then, with genuine childish simplicity, he comported himself, he says, "as if I were not zealous to dive any more into the secret of enamels," and took duly to glass-painting, and eschewed folly. But no sooner had his domestic affairs begun to assume a more prosperous aspect, than the little pet at the coy enamels was got over, and he took to his furnaces again. The furnaces soon burnt up all the fuel, and consumed all the Potter's money. In his extreme need, he flung the flooring of his house to the flames, and when that was done, the furniture followed it. No wonder that his poor wife became now positively sulky. The Potter was clearly mad now, in the eyes of all sensible people. But mad or not, he discovered his enamel, and became the greatest potter in France.

Sixteen years had been spent on this discovery, and Palissy was now bordering on fifty; yet he had accomplished his purpose, and he met with the patronage which success generally secures. In 1557 or 1558 he published a book without his name, which is either now lost or cannot be authentically identified. In the first collected edition of the Potter's works, by MM. De Saint Fond and Gobet, the *Declaration des Abus des Médecins* is supposed to be the missing treatise, and is printed accordingly among Palissy's works. High and mighty patrons now sought the humble shed of the artisan; and among the foremost was the Constable Montmorenci, who employed him to decorate his Chateau d'Ecouen, near Paris. It has already been noted that the Potter was a stanch Reformer. Reform was unfortunately not a commodity in equal demand with enamelled clay among the great and luxurious of France in those days. On the contrary, old men and simple maidens had more than once met death on the martyr's scaffold, even in remote Saintes, and under the eyes of the devout Palissy. This had not the effect of silencing the outspoken, courageous Potter; it rather made him more vehement in his denunciation of the oppressors. But for his skill in clay, his head would doubtless have fallen with the rest; but to imprison or behead old Bernard was equivalent to depriving many wealthy people of the luxury of his decorative art—a thing not to be thought of. This it was that delivered him from the Bordeaux dungeon and from the massacre of St Bartholomew's. In 1563 he published his second book, containing treatises on four subjects,—viz., agriculture, natural history, gardening, and fortification, with an appended history of the troubles in Saintonge. Here, as elsewhere, the strong original genius of the man comes out, sometimes in quite startling anticipations of scientific theories, which centuries were needed to develop and verify. Under royal patronage, the Potter removed to Paris; and at the age of sixty-five became "Master Bernard of the Tuileries." His sons aided him in his art; and he not only continued to prosecute his study of natural history, but commenced a course of lectures in the capital on scientific subjects, which were published in 1580. The doctrines of this, his last book, were a century or two in advance of his time; and it is this work which has obtained for him the admiration of men like Buffon, Haller, and Jussieu. The sturdy old Huguenot had religious enemies in abundance, who had long been anxious for his head; and when the Potter was in his seventy-sixth year, Henry III. gave way to their importunities. He was thrown into the Bastile, where he lay for the next four years. The king visited him in his dungeon one day about the end of that period, and held out to him the alternatives of recantation or death. "Sire," said the old man of eighty, "the Guiscarts, all your people, and yourself, cannot compel a potter to bow down to images of clay." Next year both king and potter had gone to their account: the former fell by the hand of the assassin, and the latter died in calm hope in the Bastile. (See *Life of Bernard Palissy of Saintes*, by Henry Morley, 2 vols., Lond. 1852.) The last and best edition of Palissy's works is entitled *Œuvres Completes de Bernard Palissy, avec des Notes et une Notice Historique*, par P. A. Cap, 8vo, Paris 1844.

Palladio.

PALLADIO, ANDREA, a celebrated Italian architect, was born at Vicenza in 1518. He began life as a sculptor, but was afterwards induced by his friend Trissino the poet to direct his attention to architecture. His generous patron took Palladio with him to Rome on three several occasions, where the young artist made a diligent study of the best specimens of ancient architecture of which that city could boast. Returning to his native town in 1547, he set zealously to work both as a practical architect and as an illustrator and expounder of his favourite art. He attained an unbounded popularity as a master of architectural design. Noble and commoner vied with each other to overwhelm the rising artist with commissions; and Pope Paul III. summoned him to Rome to obtain his professional

advice regarding St Peter's. An estimate of Palladio's character as an architect will be found in the article ARCHITECTURE. He gave the world the benefit of his artistic studies at Rome in his *Antichita di Roma*, published at Rome in 1554, and frequently reprinted. His greatest work, however, was his *Architettura*, in four books, published at Venice in 1570, and frequently reprinted, re-edited, and translated. It appeared in London in 1715, in two folio volumes, under the title, *Architecture, in English, Italian, and French, with Notes and Observations by Inigo Jones; revised, designed, and published by Leoni.* This edition was often reprinted and re-edited, and appeared both in French and Italian. The best edition of the *Architettura* is that of Vicenza, in Italian and French, in four large folio volumes, 1776–85. A new edition of his works was published in Paris, 1825–42, in folio. Palladio died in August 1580, while engaged on his greatest work, the Teatro Olimpico at Vicenza.

PALLADIUM (Παλλάδιον), an image or statue of the goddess Pallas Athene or Minerva, kept carefully hidden, and revered as the safeguard of the place where it lay. Among the ancient images of the goddess, by far the most celebrated was the Palladium of Troy, said to have been thrown from the top of Olympus by the hand of Zeus, and to have been picked up and preserved by Ilus on the building of the city. This statue was about 3 cubits high, and represented the goddess sitting with a spear in her right hand, and in her left a distaff and spindle. The safety of Troy was universally regarded as depending upon the preservation of the Palladium. Ulysses and Diomede were accordingly commissioned during the Trojan war to steal it. They effected their object despite the wrath of Pallas, who is said to have infused temporary life and motion into her image to intimidate the impious Greeks. (Virgil, *Æneid*, ii. 164, &c.) According to other accounts, the genuine Trojan Palladium was conveyed by Æneas to Italy, and was subsequently preserved with the utmost secrecy and veneration in the temple of Vesta. To account for the discrepancy in these traditions, some have alleged that the image stolen by the Greeks was simply an imitation of the real one; while others affirm that Troy contained two Palladia equally genuine. In Greece, Argos and Athens both claimed the honour of possessing the ancient Trojan Palladium; and in Italy, the cities of Rome, Lavinium, Luceria, and Siris put forward similar pretensions.

On passing into European languages, the word *palladium* came to signify any peculiar law or privilege regarded as the safeguard of the liberties of the people, or, in general, whatever affords effectual protection and safety. The term *palladium* has also been applied to a metal discovered by Dr Wollaston in 1803, associated with platinum, from which it is obtained, and which it resembles in colour and lustre.

PALLADIUS, surnamed "Sophista," or "Iatrosophista," a Greek medical writer, flourished during some period between the third and ninth centuries. The only record of his life is, that he was the author of three Greek treatises, which are still extant. The first treatise, entitled *Scholia in Librum Hippocratis "De Fracturis,"* was published in the twelfth volume of Chartier's *Hippocrates and Galen*, fol., Paris, 1679. The second treatise, entitled *In Sextum (Hippocratis) "Epidemiorum" Librum Commentarius*, has been inserted in the original Greek in Dietz's *Scholia in Hippocratem et Galenum*, in 2 vols. 8vo, 1834. The third treatise, entitled *De Febribus Concisa Synopsis*, has been published by Ideler in his *Physici et Medici Græci Minores*, 8vo, Berlin, 1841.

PALLADIUS *of Helenopolis*, one of the early Christian fathers, is generally supposed to have been born in Galatia about 367. An intense admiration for the practice of asceticism seems to have early become his distinguishing characteristic. Assuming the monkish garb at the age of twenty, he set out on foot to visit the cells of the most famous solitaries in the different parts of the Roman empire. The devout pilgrim trudged through Upper Egypt, Lybia, Syria, Palestine, Mesopotamia, and Italy, dropping in upon the ghostly fathers in the midst of their solitary devotions, marking their austerities and mortifications of the flesh, and drinking in greedily the strange stories about visions and miracles which fell from their reverend lips. All these observations and fables he began faithfully to record, after he had ultimately settled down in the see of Helenopolis in Bithynia. The book was finished about 420; and from being addressed to Lausus, a chamberlain at the imperial court, came to be known by the name of the *Lausiac History*. Palladius spent the latter part of his life in the discharge of the duties of the bishopric of Aspona. The date of his death is uncertain. The *Lausiac History*, both in the original Greek and in an old Latin version, is contained in the *Bibliotheca Patrum*, fol., Paris, 1644 and 1654. There is a Greek work, entitled *A Dialogue about the Life of St Chrysostom*, which has been ascribed to the Bishop of Helenopolis, but which is now generally attributed to another writer of the same name and the same period. (See Smith's *Dictionary of Greek and Roman Biography*.)

PALLADIUS, *Rutilius Taurus Æmilianus*, a Roman writer on agriculture, probably flourished in the fourth century. The only record of his life and labours is a treatise, *De Re Rustica*, in fourteen books. The first book introduces the subject, the twelve next treat of the agricultural operations of the twelve months of the year, and the last describes in elegiac verse the art of grafting. The work rose to high repute in the middle ages. It appears to have been often transcribed; and it was nearly completely incorporated in the *Speculum* of Vincent of Beauvais. In modern times editions have appeared by Ernesti, in 1773; and by Schneider, in his *Scriptores Rei Rusticæ*, 4 vols. 8vo, Leipsic, 1794. Among the various translations into different languages is the English version of T. Owen, 8vo, London, 1807.

PALLAS. See MINERVA.

PALLAS, PETER SIMON, a distinguished naturalist and geographer, born on the 22d of September 1741, was the son of Simon Pallas, a surgeon in the Prussian army, and professor of surgery at Berlin. He received the early part of his education in his father's house, and his instructors bore ample testimony to the rapidity of his progress. At the age of fifteen he began to attend medical lectures; and he applied himself so closely to practical anatomy, that in 1758 he was found qualified to deliver a course of public lectures on that science. In the same year he went to Halle, and became the pupil of Segner, continuing also his studies of zoology, and, in particular, of entomology, with great assiduity. In 1759 he removed to Göttingen, where he made a variety of experiments on poisons, and on other active medical substances, and commenced his observations on parasitical animals. In July 1760 he went on to Leyden, in order to attend the lectures of Albinus, Gaubius, and Muschenbroek; and at the end of the same year he took his degree of Doctor of Physic. The following summer he proceeded to England, principally with the view of completing his medical education, although he devoted the greater part of his time to the active pursuit of natural history, being assisted and encouraged by the friendship of Peter Colinson and of some other British naturalists, which procured for him, a few years afterwards, the distinction of having his name inserted in the list of the foreign members of the Royal Society, at the early age of twenty-three. He visited several parts of the coast of England, in order to examine its marine productions; and his love of natural history enabled him to profit in a similar manner

by an accident which detained him for some time at Harwich, on his return to the Continent, in the spring of 1762.

Having paid a visit to his native city, he went again to the Hague, and established himself as a resident there under the patronage of Gaubius. On occasion of the publication of a miscellaneous work on zoology, which he dedicated to the Prince of Orange, he proposed a plan for an expedition to the Cape of Good Hope, and to the Dutch East Indies, which he offered to conduct in person; but although the project was encouraged by Gaubius, and approved by the prince, his father's interference prevented its execution, and obliged him to return to Berlin. His filial affection, however, was not strong enough to induce him to refuse the invitation of the Empress Catharine to St Petersburg, where he accepted, in the year 1767, the appointment of professor of natural history in the Imperial Academy of Sciences.

The first few months of his residence at St Petersburg were employed in preparing his *Zoological Gleanings* for publication, and in making catalogues of some collections of natural history. It was now that the more active career of his public life was about to commence; and in 1768 he undertook, in common with Falk, Lepechin, and Guldenstädt, the conduct of an expedition sent out by the empress, for the joint purposes of observing the transit of Venus, and of investigating the natural history and geography of Siberia and the neighbouring countries. The object of their researches for the first summer was the province of Kasan, and the winter was passed at Simbirsk; the next year they examined the shores of the Caspian and the borders of Calmuck Tartary; after which they returned through Orenburg, and passed the winter at Ufa. In 1770 Pallas crossed the Uralian Mountains to Catharinenburg, and, after examining the mines in that neighbourhood, proceeded to Tobolsk. The next year he went to the Altaic Mountains, traced the course of the Irtysch to Kolyvan, went on to Tomsk, and observed the natural freezing of quicksilver at Krasnoyarsk, on the Yenisei, in Lat. 56. 30. N. He proceeded in March 1772 by Irkutsk across the Lake Baikal, as far as Kiatka, and returned to Krasnoyarsk. In 1773 he visited Tara, Astracan, and Tzaritzin, on the Volga, and returned to St Petersburg in 1774, after an absence of six years. About ten years later he was made a member of the Board of Mines, with an additional salary of L.200 a year; and he was complimented with the title of a Knight of St Vladimir. The empress purchased his collection of natural history for a price one-third greater than his demand, and allowed him, at the same time, to keep it in his possession for the remainder of his life.

In 1794 he took a journey into the Crimea, and was captivated with the beauty of the country and its productions; the climate also appearing to be such as his health was supposed to require, he obtained from his munificent patroness not only permission to establish himself there, but a grant of a large and fertile estate, and a sum of 10,000 rubles to assist him in his outfit. He was thus enabled to build a little palace rather than a country house, in which a traveller from the north of Europe was sure to receive the most obliging hospitality, as Dr Clarke has made well known to the English reader. It appears, however, that the air was not altogether exempt from the miasmata, which are the causes of paludal fevers; and some other circumstances, besides the distance from all civilized society, seem to have made the old age of Pallas more cheerless than he had anticipated to find it, in the independence and tranquillity of his patriarchal establishment at Akmetshet (Simpheropol.) About ten years after the period of Dr Clarke's travels, he undertook a journey to Berlin to pay a visit to his brother, and died there in September 1811.

Linné the younger has given him a genus, *Pallasia,* in his *Supplementum Plantarum;* a compliment to which his unremitting labours in every department of natural history had amply entitled him. His collection of dried plants was purchased by Dr Clarke's fellow-traveller, Mr Cripps, and passed into the possession of Aylmer Bourke Lambert. The general character of Professor Pallas's acquirements appear to have been that of extent and variety, together with fidelity. He was not the author of any new theories or improved systems: and it has sometimes been observed, as by Murray in his *System of Vegetables,* that his descriptions were somewhat defective, from the omission of correct specific distinctions; but this omission is of such a nature as to affect a compiler or a book-maker much more than an actual student of natural history, who is studying for his own improvement only, and who is capable of entering into a detailed examination of the objects concerned. To such a detail the principal part of Professor Pallas's works have relation; and it is impossible to enumerate the whole of his memoirs without making a pretty extensive catalogue of the productions of the various kingdoms of nature.

1. His *Dissertatio Inauguralis de Insectis viventibus intra Viventia,* 4to, Leyden, 1760, containing a systematic account of intestinal worms, is said to have been previously published in another form at Gottingen a short time before he went to Leyden. 2 We find in the *Philosophical Transactions* for 1763, p. 62, a short note on the Cold observed at Berlin the preceding winter. 3. In the volume for 1776, p. 186, a Description of the Jaculator Fish, or *Sciœna jaculatrix* of the Indian Ocean, which catches insects by darting drops of water at them. This description is repeated in the *Spicilegia Zoologica,* fasc 8. 4. *Elenchus Zoophytorum,* 8vo, Hague, 1766; containing nearly 300 species; Dutch by Boddaert, with figures, 8vo, Utrecht, 1768. 5. *Miscellanea Zoologica,* 4to, Hague, 1766; consisting of descriptions and dissections 6. *Spicilegia Zoologica,* 4to, Berl. 1767–1780. Of this valuable collection of memoirs, intended for the description and illustration of new or little-known species of animals, there appeared in the whole fourteen fasiculi; some of them were published by Professor Martin during the author's absence in Siberia. We find, amongst other articles, an interesting account of the musk-deer, of various species of the antelope, and on the different varieties of sheep, both wild and tame; the latter has been published in English, *On Russian and Tartar Sheep,* 8vo, Edinburgh, 1794 7. In the *N. Act. Acad. Nat. Cur*, vol. iii., p. 430, *Phalœnarum biga;* an account of two species of moth, of which the females are without wings, and spontaneously fertile. 8. A variety of miscellaneous papers, by Pallas, appeared in the *Stralsund Magazine,* which began to be published at Berlin in 1767. They chiefly relate to the Winter Residence of Swallows, vol. i., p. 20; to Hydatids found in the abdomen of ruminant animals, and supposed to be a species of Tænia, p. 64; to the Birds of Passage of Siberia, p. 145, from Heller's Notes; to Firman's supposed discovery of the Origin of the Belemnite, p. 192; to Some Peculiarities of Insects, p. 225; to a Poison supposed to be prepared in Siberia from the Sitta or nut-hatch, p. 311; to the Elk or Moose-Deer, p 382, from Heller's papers; and to the use of the Sphondylium in Kamtschatka, p 411. 9. Collections relating to the Mongol Tribes, published in 1776, and showing that they are distinct from the Tartars. 10. Professor Pallas's contributions to the *Memoirs of the Imperial Academy of St Petersburg* are also very numerous, and on miscellaneous subjects. In the *Novi Commentarii* we find an account of the *Tubularia Fungosa,* vol. ii, observed near Wolodimer; *Lepus pusillus,* and Fossil Bones of Siberia, vol. xiii.; Quadrupeds and Birds observed in 1769, vol. xiv. 1; Remains of Exotic Animals in Northern Asia, vol. xviii., especially the skulls of the rhinoceros and the buffalo; *Tetrao arenaria, Equus hemionus,* and *Lacerta apoda,* vol. xix.; the last also in *Geneesk. Jaarboek,* ii. In the *Acta* for 1777, ii., An Account of the Teeth of an Unknown Animal, like those which have been found in Canada; Observations from Camper's Letters, on a Myrmecophaga and a Didelphis, and *Equus asinus* in the wild state. In the volume for 1779, ii., a Description of Plants peculiar to Siberia; *Capra Caucasica,* also in Lichtenberg's *Magazine,* ii. For 1780, part i., *Galeopithecus vitans,* part ii., On the Variations of Animals, and *Didelphis brachyura.* For 1781, part i., *Felis manul,* a new Asiatic species of Felis; ii., on some species of Sorex. In the volume for 1783, New Species of Fishes; and 1784, On some New Marine Productions. 11. The *Observations sur la Formation des Montagnes, et les Changemens arrivés au Globe, particulièrement à l'égard*

de l'Empire Russe, published separately, 4to, Petersburg, 1777, were also inserted in the *Acta* of the Academy for 1777, having been read at a public sitting before the King of Sweden. A translation of this discourse is inserted in Tooke's *Russian Empire*, and some remarks on it are found in the *Journal de Physique*, vol. xiii. 12. The most considerable of the separate publications of Pallas was the account of his travels, entitled *Reise durch verschiedene provinzen des Russischen Reichs*, 3 vols. 4to, Petersburg, 1771–3–6; French, 8vo, Paris, 1803; English, 2 vols. 4to, London, 1812; a work of the highest authority in geography and natural history. 13. It was in the course of these travels that Pallas observed in Siberia an insulated mass of native iron which he described in a paper addressed to the Royal Society of London, and printed in the *Philosophical Transactions* for 1776, p. 523; a substance which has become the subject of many discussions, from its resemblance to some of the specimens of well-ascertained aerolites; the author mentions also the remains of an unmineralized rhinoceros, which had been found in the same country. 14. In the *Beschaftigungen Naturforschenden Freunden*, published at Berlin about 1777, we find a letter on the *Acipenser ruthenus*, or sturgeon, vol. ii., p. 532; and An Account of a Monstrous Horse, vol. iii., p. 226. 15. Some Mineralogical Observations, addressed to Born, are published in the *Böhmische Abhandlungen*, vol. iii., p. 191. 16. In the Swedish *Handlingar* for 1778, we have the *Alauda Mongolica*, and the *Sturnus Dauuricus*; the *Anas glocitans*, in 1779. 17. *Novæ species Glirium*, 4to, Erlangen, 1778. 18. *Icones Insectorum, præsertim Rossiæ Sibiriæque*, 4to, Erlangen, 1781. 19. *Enumeratio Plantarum Procopii a Demidoff*, 8vo, Petersburg, 1781. 20. Another channel in which a number of Pallas's most valuable essays appeared is the work entitled *Neue Nordische Beyträge*, which he published at St Petersburg and Leipsic in 1781 and the following years. The most remarkable of the subjects of these are A Great Exotic Animal found in Kasan in the year 1776; on the Migration of the Water-Rat on the Volga, and Observations on Tæniæ, vol. i.; further Remarks on Tæniæ; on American Monkeys bred at St Petersburg; on the *Ardea helias*; on the *Culex lanio*, sometimes fatal to cattle, on the Phalangium, or Scorpion Spider; and on Copper Island, in the Sea of Kamtschatka, vol. ii.; on Two Birds; and on the Labrador Stone, vol. iii.; on a Cross of the Black Wolf with the Dog; on a Mine; on the Oriental Turquois; and Mineralogical Novelties from Siberia, vol. v. 21. In the *Physische Arbeiten* of Vienna, we have a geological Essay on the Orography of Siberia, vol. i. 1. 22. *Flora Rossica*, f. vol. i., Petersburg, 1784; ii., 1788, published at the expense of the empress. 23. *Tableau Physique et Topographique de la Tauride*, 4to, Petersburg, 1795; German, in *N. N. Beyträge*, vii.; a work derived chiefly from the observations made by the author in his travels of 1792. 24. A Monography of the Astragali is mentioned by some of his biographers. 25. He edited also Guldenstadt's *Reisen durch Russland und in den Caucasischen gebirgen*, ii., v., 4to, Petersburg, 1787–1791. 26. He also compiled and arranged the two first and most valuable of the four volumes of the *Vocabularia Comparativa*, 4to, Petersburg, 1787, in which he attempted to make some improvements in the Russian orthography.

(Coxe's *Travels*; Clarke's *Travels*; Tooke's *Russian Empire*; Halleri *Bibliotheca Anatomica*; Aikin's *General Biography*, vol. x., 4to, London, 1815; Chalmers' *Biographical Dictionary*, vol. xxiii., 8vo, London, 1815; Dryander, *Catalogus Bibliothecæ Historico-Naturalis Josephi Banks, Bart.*) (T. Y.)

PALLAVICINO, Ferrante, an Italian litterateur, who owes his celebrity as much to his misfortunes as to his genius, was descended from a noble family, and was born at Piacenza about 1618. He received an excellent education, and gave early proof of very great abilities. In compliance with the desire of his parents, he entered the church, took the habit at the monastery of the Augustine friars at Milan, and joined the house of his order at Venice. For a time he bore a high character for piety and learning, but a love intrigue with a fair Venetian led to his deserting the monastery, and was the beginning of a course of debauchery and general misfortune which ended only with his life. Need drove him to authorship; and among other minor efforts, he wrote a collection of satirical letters, called *The Courier Robbed of his Mail.* It was bitter against the Spaniards, whom the author disliked, but the Inquisitors licensed its publication. The secretary of the republic, however, declined giving it his *imprimatur*, which caused Pallavicino to vow vengeance upon that functionary. On returning from a residence in Germany, where he at once acted as chaplain to the Duke of Amalfi, and played the libertine, he resolved to wreak his anger upon all who had endeavoured to prohibit his manuscripts. He re-cast and enlarged his *Courier*, and got a bookseller to pass it secretly through the press. When on the eve of completion, however, a pretended friend, who played the spy, disclosed the matter to the Pope's nuncio, and the unfortunate author was thrown into prison. Having obtained his liberty, mainly by the aid of one of his mistresses, he wrote a piece called *La Buccinata overo Butarella per le api Barberini*, consisting of a bitter satire on his enemies the Barberini, with a dedication, expressive of the most exquisite contempt, to the Nuncio Vitelli. The ecclesiastic adopted the foulest means of revenge. He bribed a base Frenchman to decoy the unsuspecting poet into the hands of a gang of *sbirri*. Pallavicino was conveyed to Avignon, and, on pretence of carrying contraband goods, was thrown into prison. A mock trial was got up, at which he made a skilful defence; but it was all to no purpose. He was sentenced to death, and lost his head upon the scaffold on the 5th of March 1644, at the age of twenty-six. In addition to the productions already alluded to, Pallavicino wrote a number of smaller pieces, all characterized by that happy grace and fine genius which his larger works display. His *Opere Permesse*, edited by Brusoni, with a Life of the author, were published at Venice in 4 vols. 12mo, 1655; but his *Opere Scelte*, Geneva, 1660, is the edition most prized by the curious.

PALLEE, a town of India, in the Rajpoot state of Joudpore, 108 miles S.W. of Nusseerabad, and 351 S.W. of Delhi; N. Lat. 25. 48., E. Long. 73. 24. It is an ancient town, and was formerly surrounded by walls; but these were destroyed at the request of the inhabitants; as they made the place an object of contest in the civil wars of Joudpore. Pallee belongs immediately to the sovereign of Joudpore, and is not subject to any inferior feudal lords. He obtained from it an annual revenue estimated at L.7500. It is a place of considerable trade, as it stands at the intersection of the commercial routes from Cutch to the northern provinces, and from Malwah to Sinde. Pop. estimated at 50,000.

PALLIUM and Palla were generic terms applied, like ἱμάτιον and φᾶρος, to an outer garment worn by the Greeks, and occasionally by the Romans, both male and female, but so extensive in signification, that we find these words not unfrequently employed to denote a blanket or rug, rather than a "cloak" or "garment." The article so designated was a piece of cloth, always rectangular in shape and frequently square, varying in colour and material according to the rank or taste of the wearer. It was generally manufactured from wool, flax, or cotton; and certain qualifying epithets or specific designations were given to the pallium to indicate the diversity in the materials from which the cloth was made. The most graceful and convenient mode of wearing the pallium was first to pass it over the left shoulder, then to draw it behind the back and beneath the right arm, and then to throw it again over the left shoulder. A very common mode of wearing the pallium was to fasten it with a brooch over the right shoulder. It was not unfrequently, however, folded about the body, simply with the view of protecting the wearer from the cold, and without any regard to grace or convenience. Diogenes Laërtius (vi. 6, 13) informs us that the cynic Antisthenes "first doubled his pallium," a contrivance afterwards imitated by the rest of the fraternity, and especially by Diogenes, who slept and died in his one. This was the more necessary, however, in the case of those stern sages, as they, contrary to the usual custom, often went without a tunic. Socrates also adopted the practice of discarding the underclothing. The pallium worn by boys was different from that used by men; but women sometimes wore

the pallium of the other sex. Where means would allow, however, the Greek ladies generally adorned their persons with pallia smaller in size, finer in texture, and more gorgeously coloured than those worn by men; although it was by no means a rare thing to see the more effeminate class of men attire themselves in the splendid pallium of the ladies. The *toga* among the Romans answered to the pallium among the Greeks; and so strong was the prejudice of the former nation in favour of their peculiar blanket, that they invariably regarded the adoption of the pallium by any Roman as an affectation of Grecian or foreign manners. Hence the employment of the national epithet *togatus* by the Romans, to distinguish themselves as the nation of the toga or gown from all other nations.

PALLIUM is the name applied in the Roman Catholic church to that peculiar vestment bestowed by the Pope upon all patriarchs and archbishops. It was formerly customary for those functionaries to make a pilgrimage to the Holy City for the purpose of receiving the pall, but other means are now adopted for delivering it to them. The material for the ecclesiastical pallium is obtained from the wool of two lambs slain on the eve of St Agnes. This symbol of the plenitude of ecclesiastical power is deposited on the tombs of St Peter and St Paul, where it is left all night. It is afterwards, when duly consecrated, laid aside by the subdeacons until demanded by those for whom it is designed, whether in person or by proxy. The modern pallium of the church is a short white cloak ornamented with a red cross, which encircles the neck and shoulders, and falls down the back. These palls are purchased from his Holiness at a very considerable sum; and no archbishop can perform the duties of his office before receiving the pallium, nor is it legitimate for him to use that of his predecessor. (See Ersch and Gruber's *Encyclopädie*, article "Pallium.")

PALM. See under *Palmæ* in BOTANY, Nat. Ord. 251.

PALM OIL. See OILS.

PALM-SUNDAY, the name given to the Sunday immediately preceding Easter, from the boughs of palm trees which used to be carried to the church on that day by the worshippers, in imitation of those which were strewn in the way of Christ when he went up to Jerusalem. (Fuller's *Church History*, p. 222.) The author of the *Festival*, as quoted by Brand (*Popular Antiquities*), says,—"It is called Palme Sondaye for bycause the palme betokeneth vyctory, wherefore all Crysten people sholde bere palme in processyon in tokennynge that he hath foughten with the fende our enemye, and hath the vyctory of hym." Branches of willow, box, and yew being more accessible than palm, are generally employed in Roman Catholic countries, and go by the general term of palms. The palm branches, on being borne to the church, are thrown together in a heap, and after being duly blessed by the priest, the worshippers carry portions of them away again, in the belief that they thus afford a sure protection against "winter stormes and thunders." (See Barnaby Googe's translation of Naogeorgus in his *Popish Kingdome*, 1570.) A wooden ass, surmounted by a rider of the same material, seems also occasionally to have formed a part of the procession on Palm Sunday. The author of the *Pylgremage of pure Devotyon*, 1551, gives a satirical glance at this practice in his preface when he says,—"Upon Palme Sondaye they play the foles sadely, drawynge after them an asse in a rope, when they be not moche distante from the wooden asse that they drawe." As appears from authorities quoted by Brand, it was customary also to deck private dwellings and churches with the branches of the palm at this interesting season. (Vol. i., p. 120, Bohn's edition.) The ceremonies of Palm Sunday were retained in England for a considerable time after other practices peculiar to the Church of Rome had been abandoned. This ceremony was to be retained by an express declaration of Henry VIII. in 1536; but in the reign of Edward VI. it seems to have ceased. It is still customary with boys, however, in some parts of England to "go a palming," and gather slips of willow, flowers, or buds at this season. In Russia, the Greek Church seems to hold a very solemn procession on Palm Sunday.

PALMA, a town of Spain, in the province of Cordova, at the union of the Genil and Guadalquivir, 30 miles S.W. of Cordova. The streets are wide and well paved, and the buildings generally good. The court-house, jail, church, convents, school, hospital, &c., are the chief public establishments. The principal manufactories are oil-mills; but flour, soap, earthenware, bricks, &c., are likewise made here. Some trade is carried on in timber, corn, fruits, oil, and cattle. Pop. 5528.

PALMA, a town of Naples, province of Terra di Lavoro, stands on a beautiful hill to the N.E. of Vesuvius, 4 miles S. of Nola. It contains several churches and convents, an old castle, and a feudal mansion belonging to the King of Naples. Pop. 6789.

PALMA, a town of Sicily, province of Girgenti, and 14 miles E S.E. of that town. It has several churches, and many good houses. On a hill to the west stands the large square castle of Monte Chiaro. Some trade is carried on in almonds and sulphur. Pop. 8400.

PALMA, GIACOPO, surnamed "the Old," an eminent Italian painter, was born near Bergamo about the beginning of the sixteenth century. He was a patient and laborious artist, and studied to catch the grace of Titian, and the clear expression and lively colouring of Giorgione. Accordingly, an elaborate refinement and a harmony of tints became his characteristic excellences Among other great pictures, he painted "Saint Barbara" for the church of Santa Maria Formosa at Venice, and a "Madonna" for San Stefano di Vicenza. He is also the supposed artist of a portrait which has been warmly eulogized by Vasari as "a performance of astonishing perfection and singular beauty." His death took place at Venice in the forty-eighth year of his age. Several pictures ascribed to Palma, including some that are not well authenticated, are found in the galleries of Dresden, Vicenza, Venice, Vienna, and other European towns.

PALMA, *Giacopo*, surnamed "the Young," was the grand-nephew of the preceding, and was born at Venice in 1544. Many favourable circumstances combined to assist him in his progress towards eminence. After receiving his first lessons from his father, a painter of some repute, he exercised his hand in copying from Titian and the best of the native masters. Then being sent to Rome at the expense of the Duke of Urbino, he spent eight years in copying from the antique, and in studying Michael Angelo, Raphael, and especially Polidoro. On his return to Venice, when Tintoretto and Paul Veronese were monopolizing all the employment in that city, Vittoria, an eminent sculptor and architect, patronized him, gave him advice, and brought him into notice. By these means did Palma attain to such a reputation that, on the death of his two great rivals, he began to be overwhelmed with commissions, and his pictures came to be appreciated for their rich and animated composition, and their fresh and transparent colouring. Yet it was this very rise in popular estimation that led to his decline in art. The hurry resulting from his numerous and pressing engagements betrayed him into negligence. Unless when he was allowed to take his own time, and name his own remuneration for any particular painting, he was wont to dash off pictures which were little else than rough draughts. This evil influence did not stop with his death, in 1628. It affected the rising artists of the same school, and introduced the most corrupt period of Venetian art. One of Palma's most celebrated pictures is his "Plague

of the Serpents" in St Bartolomeo. (Lanzi's *History of Painting*.)

PALMAS, Las. See Canary Islands.

PALMI, or Palme, a town of Naples, in the province of Calabria Ultra I., on the shore of the Bay of Gioja, occupies one of the most beautiful situations on this beautiful coast. It stands on the flat top of a rock rising steeply from the sea, and is surrounded by gardens and orange and olive groves; while the mountains in the background are covered with luxuriant forests of chestnuts. From the town is obtained a magnificent view of the Italian coast on the N.; the strait and town of Messina, and in the distance Mount Etna, on the S.; and the northern shores of Sicily, with the Lipari Islands, on the W. The streets are regularly built, and many of the houses are very handsome. In the public square there is an elegant fountain in the shape of a palm tree. Part of the town was destroyed by the earthquake of 1783, but it has since been restored. It contains several churches and some silk factories. There is some trade in oil, wines, &c. Pop. 6600.

PALMUS, a measure of length used both by the Greeks and the Romans. The Grecian *palmus* was of two sorts,—the greater (σπιθαμή), which contained nine finger-breadths, and the less (παλαιστή), which contained four. The Roman *palmus* was also of two sorts,—the greater, which contained twelve finger-breadths, or about 9 inches English; and the less, which contained four finger-breadths, or about 3 inches English. The greater *palmus* was taken from the length of the hand or span, the less from the breadth of it. (See Weights and Measures.)

PALMYRA, or Palmira (Gr. Παλμύρα, Ptol. Appian; Παλμίρα, Joseph.), "The City of Palm Trees," is the name given by Greek and Roman authors to an ancient city of Syria, which is called by the sacred historians *Tamar* or *Tadmor* (Heb. תָּמֹר, 1 Kings ix. 18; תַּדְמֹר, 2 Chron. viii. 4,—words having the same signification), and which is still known by the Arabs under the name *Tedmor*. The identity of Tadmor with Palmyra is not only inferred from the similarity of the names, but rests also on the authority of Josephus. It stands in an oasis in the Syrian desert, about half-way between the Euphrates and the Orontes, and about 140 E.N.E. of Damascus; N. Lat. 34. 24., E. Long. 38. 20. Tadmor is said in the passages of Scripture already cited to have been built by Solomon; but it cannot be thence inferred that no city had previously existed on this site. On the contrary, there are considerations which lead us to suppose that Solomon only enlarged, and, as Josephus informs us, fortified, the more ancient town of Tadmor. It is plain that the site of the town must always have been important as a station in the desert while any route of travel led across this region; and that this existed at a very early period, appears not only from the communication between Mesopotamia and Palestine, as early as the time of Abraham, but from the mention by Moses of Indian products, such as cinnamon (Exod. xxx. 25), which were probably conveyed by this route to the West. The object of the Hebrew monarch in taking possession and increasing the size of Tadmor evidently was, to retain in his own hands the profitable traffic with India by means of the Euphrates and the Persian Gulf; and the place is accordingly described by ancient writers as inhabited chiefly by merchants, and proverbial for its wealth and luxury. This Indian trade is with much probability conjectured by Volney to have been the cause of many of the wars and revolutions of the East in ancient times, and it was probably this as much as any other motive that directed the continual efforts of the Assyrian and Babylonian emperors against Palestine and Phœnicia, until both of these once powerful nations were reduced under their supremacy. As long as Jerusalem and Tyre continued to flourish, Palmyra occupied a very subordinate position, and it is not mentioned in the history either of the expedition of the younger Cyrus or of the campaigns of Alexander. The decline of its rivals, however, under the successors of Alexander, paved the way for the subsequent accession of power acquired by Palmyra.

It is first mentioned by the Roman historians as a place which Marcus Antonius attempted to plunder, upon pretence that it had not observed a just neutrality between the Romans and Parthians. Under the early Roman emperors, Palmyra was an independent city, and a place of some importance, holding a position between the two great empires of that time, the Roman and the Parthian. In 130 A.D. Palmyra submitted to Adrian, and from this period rapidly increased in wealth and power. Though nominally subject to Rome, it had a senate and popular assembly of its own, as is seen from the inscriptions found among the ruins. In the middle of the third century, when the Roman empire was weakly governed by Gallienus and Valerian, Palmyra rose to its highest degree of power. When the defeat and captivity of Valerian by the Persians, in 260 A.D., had so much weakened the empire that its adversaries seemed to be in a fair way of becoming masters of all the eastern provinces, Odenathus, a noble of Palmyra, took up arms against Sapor, the Persian monarch, whom he defeated, and expelled from Syria and Mesopotamia. For these services he was rewarded by Gallienus with the title of Augustus, and acknowledged as his colleague in the empire.

Odenathus enjoyed his sovereignty but a very short time, being murdered about the year 266 by his nephew, who was soon afterwards put to death by Zenobia, the wife of Odenathus. This celebrated woman, who assumed the title of Queen of the East, was not more remarkable for her bold and martial achievements than for her intellectual acquirements, and for the patronage she bestowed on literature, particularly in the person of Longinus, the greatest philosopher of his age. By his advice, she wrote a letter to Aurelian, who had assumed the purple in 270, declaring her independence,—a step which did not fail to provoke the hostility of that emperor. He accordingly passed over into Asia, and routed the forces of the Queen of the East, under the command of Zabdas, in two separate engagements fought near the gates of Antioch, and under the walls of Emesa. Zenobia finding it impossible to collect a third army, withdrew to Palmyra as her last resource, and prepared for a desperate resistance.

"The Roman people," says Aurelian, in an original letter, "speak with contempt of the war which I am waging against a woman. They are ignorant both of the character and of the power of Zenobia. It is impossible to enumerate her warlike preparations of stones, of arrows, and of every species of missile weapons. Every part of the walls is provided with two or three balistæ, and artificial fires are thrown from her military engines. The fear of punishment has armed her with a desperate courage. Yet I trust still in the protecting deities of Rome, who have hitherto been favourable to all my undertakings." The courage of the queen was supported by the hope of aid from Sapor of Persia. That monarch died, however, during the course of the siege, and the unfortunate heroine, driven to the last extremity, resolved to fly. Mounting her fleetest dromedary, she scoured the desert for 60 miles, but was overtaken and captured by Aurelian's light horse on the banks of the Euphrates. She was brought a captive to the feet of the emperor, and her capital soon afterwards surrendered.

After the surrender of Palmyra, Zenobia was conveyed as a captive to Rome, to grace the conqueror's triumph; while many of her advisers, and among the rest Longinus, were put to death. Aurelian had hardly set foot on the shores of Europe, when intelligence reached him of the massacre of the governor and garrison he had left at Pal-

myra. Without a moment's deliberation, he turned his face eastward, and the fated city felt the full weight of his resentment. The destruction of Palmyra took place in 273 A.D.; but, in pity for the remnant of the inhabitants, permission was granted to rebuild and occupy it. (See Gibbon's *Decline and Fall*, vol. ii., chap. xi.) After this period, however, the city gradually declined. It was indeed enlarged by Diocletian, in whose reign it was a military station, and Justinian strengthened its fortifications; but the decline of the Roman empire seems to have soon led to the abandonment of the place. It was taken by the Saracens under the caliph Abu Bekr, the successor of Mohammed, and was a place of some importance in the wars between the different factions of the Prophet's followers. In the twelfth century Palmyra was visited by Benjamin of Tudela, who states that it was then surrounded with a wall, and inhabited by 2000 Jews. In 1400 it was plundered by Tamerlane; but after this period Palmyra is not again mentioned in history. Until nearly the end of the seventeenth century the magnificent ruins of Palmyra were known only to the Arabs, by whom, in 1678, an expedition by certain English merchants at Aleppo was rendered abortive; and after the success of a second attempt in 1691, the description they gave of the remains received little credit. These earlier reports were, however, confirmed by Wood and Dawkins, who visited Palmyra in 1751, and published a full account of the ruins they found there. But these descriptions were regarded as somewhat exaggerated by Irby and Mangles, who examined the place in 1816. Since that period several other travellers have visited Palmyra, and given accounts of its remains.

The ruins stand at the eastern foot of a chain of hills extending north and south, and they present, on the first view, an extremely fine appearance,—contrasting by the pure whiteness of their innumerable columns with the yellow sand of the desert. The Arabian village of Tedmor consists merely of a collection of mud hovels in the court of the great Temple of the Sun; but all the rest of the ruins are free from the incumbrance of any modern structures. The inhabitants of both sexes are well shaped, and the women, though very swarthy, have good features. They are veiled, but do not so scrupulously conceal their faces as the eastern women generally do. They stain the ends of their fingers and the palms of their hands red, their lips blue, and their eyebrows and eyelashes black. They have large rings of gold or brass in their ears and nostrils, and appear to be healthy and robust. The numbers of the inhabitants are continually fluctuating. Mr Addison, who visited the ruins in 1835, states that there were then only twelve or fifteen families in the village; while in 1851, when the Rev. J. L. Porter was there, the place contained seventy or eighty families, though since that time he states that it is reported to have been deserted by nearly half the people, on account of a private quarrel. They live chiefly by trading with the Bedouins and the people of Damascus, to which city they convey large quantities of salt, obtained from the desert south of Palmyra. A few small gardens are cultivated, producing vegetables and corn; and in these still flourish a number of the palm trees that once gave its name to the city. As the whole of the ruins are covered to some height with drifting sand, which seems to have come down from the eminences to the S.W. of the town, it is probable that some change has taken place in the surface of the country; for the splendid buildings and colonnades would scarcely have been erected in a position where it would require constant labour to keep them clear of sand. Although some travellers have represented the buildings of Palmyra as constructed of marble, the material almost universally employed is white limestone from the adjacent hills, which are of that formation. Several shafts, however, are of Syenite granite, one of which, 30 feet long and 3 in diameter, must have been conveyed with immense labour and difficulty from Upper Egypt, a distance of nearly 200 miles. The ruins of Palmyra cannot properly be compared with those of Bâ'albek, for, though less gigantic, they are far more extensive and various. The ancient walls, which may still be traced, and which are supposed to be those of Justinian, have a circumference of 3 miles; while we have reason to believe that the ancient city extended far beyond these limits, and if we may believe the Arabs, covered an area 10 miles in circumference. "Here," says Addison, "over an immense area, we wander through the ruins of long porticoes leading up to ruined temples and unknown buildings. Now we see a circular colonnade sweeping round, with its ruined gateway at either end; now we come to the prostrate walls or ruined chambers of a temple or a palace; anon we explore the recesses of a bath or the ruins of an aqueduct; then we mount the solitary staircases, and wander through the silent chambers of the tombs, ornamented with busts, inscriptions, and niches for the coffins stored with mouldering bones; and from the summits of funereal towers, five storeys in height, we look down upon this mysterious assemblage of past magnificence, and beyond them upon the vast level surface of the desert, silent and solitary, stretching away like the vast ocean, till it is lost in distance." (Vol. ii., p. 286.) The capitals of the columns, and the more delicate sculptures, have been much injured by the sciroc wind of the desert; but those parts which have been sheltered from its corroding influence present the most beautiful and minute carving.

Like many other ancient cities of Syria, Palmyra contains a grand colonnade, which extends from S.E. to N.W., and is intersected near the middle by another at right angles to it. At the S.E. extremity is a triumphal gateway, with three arches; and at the intersection of the two colonnades are four stone platforms, which once supported as many statues. The avenue consisted of four rows of columns, of which it must have contained upwards of 1500, more than 150 still remaining. They are 57 feet high, including the bases and capitals, and finely proportioned, though the details are not so tasteful as those of the great temple. A richly-sculptured entablature surmounted the columns, and must have added to the magnificent appearance of the whole when entire. This colonnade seems to have been one of the places set apart by the Palmyrenians for monuments to their distinguished citizens, as most of the pillars have brackets projecting from them for supporting statues, and inscriptions below containing the name of the individual. One of these inscriptions is important, as establishing, by its date and the historical persons mentioned, the fact that the era in use at Palmyra was that of Seleucus, B.C. 312. The dates found on the various columns, however, cannot be taken as fixing the period when the colonnade itself was erected; but they give evidence that this must have been previous to 238 A.D. From the grand avenues many smaller colonnades diverge in various directions, leading to the numerous temples and other buildings that occupy the space around the avenues. This seems to have been an ornamental part of the town, kept quite distinct from the rest, which lay more to the north. It is impossible to describe all the various buildings which crowd the site of the city of Zenobia, and which are, many of them, remarkable for elegance and beauty. The most magnificent of these, however, the great Temple of the Sun, deserves a more particular account. It stands on a rising ground near the south-eastern end of the town, and must have presented, when entire, a most splendid appearance. The outer court, a perfect square, 740 feet every way, was inclosed by a lofty wall pierced with numerous richly-carved windows, between which, on both sides, are Corinthian pilasters surmounted by a frieze and cornice. On the west side was

the grand entrance, consisting of a portico of ten pillars, 138 feet in length, approached by a magnificent staircase. All this, however, has been disfigured by a huge square tower, built by the Saracens, who used the temple as a fortress. The central door, whose sides and lintel are composed of single blocks of stone, is 32 feet in height and 15 in breadth; and is surrounded with beautifully-carved vine branches and clusters of grapes; while the two side doorways are half the size of the central one. The interior area, which was paved with large square stones, was surrounded on every side but the west, where there was a single row, by a double range of pillars 37 feet high, each having on a bracket the statue of some distinguished individual. The number of the columns was 390; but of these only about 60 now remain. In the centre of the area, on a raised platform, stood the temple itself, towering above the adjacent edifices. It stands north and south, having its door on the west side, facing the grand entrance; and it is surrounded by a row of Corinthian columns 64 feet high, and a cornice running all round, with boldly-carved wreaths of flowers and fruit. The door is 33 feet high by 15 wide, and has over it an eagle with outspread wings, similar to that in the temple at Bâ'albek. The roof of the temple is entirely gone, and the interior has been much defaced by the fanaticism of the Mohammedans, who employ the southern end as a mosque. At each extremity of the building, which is 134 feet long, exclusive of the colonnade, is a semicircular vaulted chamber, with a richly-sculptured roof, that at the north end having representations of the signs of the zodiac. This magnificent temple is considered by Porter, as a whole, to be scarcely surpassed by any in the world. "The temple of Minerva at Athens, and a few of its fellows,—the *chef d'œuvres* of ancient Greece,—are undoubtedly more beautiful in their stern simplicity, and in the brilliancy of their marble columns. Bâ'albek, not less chaste in its sculpture, is more gigantic in its proportions; but the cloistered court at Palmyra, with its long lines of statues, and the temple itself towering high over all, formed a picture unique and unequalled by any of these." (Vol. i., p. 238.) Besides the temples and colonnades, there are at Palmyra numerous tombs, many of which are curious and interesting. There seem to have been two cemeteries near the town, one of which, supposed to be the more ancient, as it contains no Greek inscriptions, lies in the plain to the S.W., while the other occupies the sides of the valley through which the road leads westward. Some of the tombs are hewn out of the rock; others are towers several storeys in height. They generally contain receptacles for coffins, arranged in tiers; most of them have inscriptions, and many are adorned with sculpture. One of the aqueducts that supplied the city with water runs through the valley in the west from a source in the northern mountains. It is built of hewn stones, and is 8 feet high by 4 broad. There was also another aqueduct, the source of which is not known, but of which traces have been observed to the N. of the great temple. From a fountain, near which is an ancient altar of Jupiter, to the S.W. of the city, flows a sulphureous stream, which supplies the modern inhabitants, and waters their few gardens. The inscriptions on the various columns and buildings of Palmyra are numerous, and are written both in Greek and in the Palmyrene characters, which have a considerable resemblance to the Hebrew. The earliest date that has been found in Greek is 314 of the Seleucian era (A.D. 2); but the Palmyrene inscriptions are believed to be much more ancient. As many of the tombs have never been opened, and as the Palmyrene tongue has not yet been deciphered, it is possible that some additions to our knowledge of ancient history may be derived from these inscriptions, though most of the Greek ones contain little more than names and dates. Of the more modern buildings at Palmyra, the only one that deserves notice is the Saracenic castle, which stands on the hills to the N.W. of the town, commanding a fine view of the whole of the ruins. It is said by the Arabs to have been built by Man Ogle, a Druse prince; but it is now entirely deserted.

Such is the present condition of the renowned city of "Palmyra, central in the desert;" a city which was once the seat of wealth and of learning—the capital of a nation that defied the power of Rome—the chief emporium on a route by which of old the wealth of India was conveyed to the West—and which, though now traversed only by the wandering Bedouin or the adventurous traveller, seems likely to become again the highway to the East. The wretched huts of the present inhabitants, contrasting with the splendour of the ancient remains, show how fatal to Palmyra has been its conquest by the followers of the Prophet. (See *Damascus and Palmyra*, by Charles G. Addison, London, 1838; *Five Years in Damascus*, by the Rev. J. L. Porter, A.M., F.R.S.L., London, 1855.)

PALO, a town of Naples, province of Bari, stands on a steep rock rising above the left bank of the Sele, 11 miles S.W. of Bari. It contains two convents, and has manufactories of soap. Pop. 4650.

PALOMAR, SAN ANDRES DE, a town of Spain, province of Barcelona, and 4 miles north of that town. It contains a small church of Moorish style, a court-house, and several schools. Weaving, spinning, and lace-making are carried on; and the town is in a flourishing state. Pop. 4345.

PALOMINO DE CASTRO Y VELASCO, ACISCLO ANTONIO, "the Vasari of Spain," was born of a good family at Bujalance in 1653. He received an excellent education at Cordoba in grammar, philosophy, theology, and jurisprudence; but his taste for art triumphed over his love of letters. Cordoba was visited by Valdés Leal in 1672, and by Alfaro in 1675. They were both painters of reputation, and they bestowed much care on the instruction of Palomino. Both did what they could to stimulate him in the study of his art, and both strove to smooth his way to advancement. Having a vague hankering towards the church, he took minor orders sometime before 1678, when, on the advice of Alfaro, he repaired to Madrid to prosecute the study that lay nearest his heart. Here painting and mathematics, the society of artists and men of letters, occupied his time till the death of his friend Alfaro in 1680 called him to complete the pictures left by that artist on the easel. Palomino soon afterwards married a lady of rank, was appointed alcalde of the Mesta, and was thus raised to the rank of nobility. He continued to prosecute his art with some degree of success; and in 1688 was made painter to the king. He visited Valencia in 1697, where he remained three or four years, and left behind him a number of feeble frescoes in the principal churches there. Salamanca, Granada, and Cordoba were visited successively in a professional capacity between 1705 and 1715. It was during the latter year that the first volume of his great work on art made its appearance. On its completion in 1724, it bore the title *El Museo Pictorico y Escala Optica*, 2 tom. fol., Madrid, 1715–24. The first volume contains some valuable disquisitions on painting, much silly gossip about miraculous images, and numerous practical hints to artists, at once prolix and pragmatical. The portion of his work devoted to the biography of Spanish artists, entitled *El Parnaso Español Pintoresco Laureado* ("The Picturesque Laurelled Spanish Parnassus"), without being remarkable for accuracy, is nevertheless a perfect storehouse of facts, traditions, and quaint, facetious stories, of which subsequent writers have freely availed themselves. There is an honest, garrulous simplicity about his narrative; and, curious to say, he is much more given to praise than to blame his brethren of the brush when he has occasion to be critical. As a writer he does not stand much

higher than as an artist; yet the learning and industry which he brought to bear upon his history of art have formed the mainstay of his reputation, and have preserved his name from oblivion. The latter days of Palomino were spent as a churchman. His wife dying in 1725, and his own health having given way, he received priest's orders during the same year. He died on the 13th of August 1726. Palomino's History was partially translated into English in 1739; an abridgment of it in the original appeared at London in 1744, afterwards translated into French, with additions, in 1749; and a reprint of the entire work was issued from the press at Madrid in 1797. (See Stirling's *Annals of the Artists of Spain*, vol. iii., pp. 1120–1134.)

PALOS, a small seaport of Spain, province of Huelva, on a bay of the Atlantic. From this place Columbus sailed, August 3, 1492, on his first voyage; and here he landed, March 15, 1493, after the discovery of America. Here also Cortes landed in 1528, after the conquest of Mexico. In the neighbourhood is the convent where Columbus, asking alms, was received by the prior, Juan Perez de Marchena, through whose influence at court he was permitted to undertake his voyage.

PALOTA, a market-town of Hungary, county of Veszprim, 13 miles W. of Stuhlweissenburg. It contains a castle, several churches belonging to different sects, a synagogue, and an orphan hospital. There are here several mills and woollen factories.

PALU, or PALOO, a town of Asiatic Turkey, pashalic of Diarbekir, stands on the eastern branch of the Euphrates, at an elevation of 3292 feet above the sea, 55 miles N. of Diarbekir. It has a castle; and is surrounded by a rich and well-cultivated country, with numerous gardens and vineyards. About three-fifths of the population are Mohammedans, and they are almost the sole landowners and farmers. The Armenians, who form the rest of the inhabitants, are heavily taxed. Weaving, dyeing, and tanning are actively carried on. Pop. about 5000.

PALUDAMENTUM was a habit among the Romans, differing little, if at all, from the chlamys. It was worn by the officers and principal men in time of war, who were therefore called *paludati;* and this distinguished them from the common soldiers, who, because they wore the *sagum,* were called the *sagati.* The *paludamentum,* which was generally white or red, came down to the knees, or lower, was open in front, hung loosely over the shoulders, and was fastened across the chest by a clasp.

PAMIERS, a town of France, in the department of Ariège, capital of an arrondissement of the same name, stands on the right bank of the Ariège, 11 miles N. of Foix. It is a neat and cheerful place, containing a cathedral with a brick Gothic tower, several other churches, a convent, bishop's palace, court-house, several schools, and a large hospital. It is the seat of a court of the first resort; and has manufactures of nails, files, paper, serge, and woollen cloth. Some trade is carried on in corn, wool, horse-hair, &c. In the village of Carlat, not far from Pamiers, the celebrated Bayle was born in 1647. Pop. (1856) 7267.

PAMIR, or PAMERE, an elevated region in Central Asia, to the N. of the Hindu Koosh Mountains, forms a part of Independent Tartary. It contains the lake from which the Oxus takes its origin; and has some mountains rising to the height of 1900 feet above the sea. The inhabitants of this country are Kirghises, who pursue a wandering and pastoral mode of life. The pasturage is good, but the climate is very cold, and snow lies in some parts all the year round.

PAMPAS, vast plains in South America, extending over an area of 1,620,000 square miles, and occupying nearly the whole of Patagonia, and all the central part of the Argentine Republic. They are traversed by numerous rivers; and while in some parts they are covered with grass, in others the ground is of a swampy and marshy character.

PAMPAS DEL SACRAMENTO, extensive plains occupying the N.E. and less known parts of Peru, having an area of about 60,000 square miles. They are of great fertility, and in many parts have been cultivated. In some places they are covered with dense and luxuriant forests.

PAMPHILUS, a benevolent promoter of learning in the early church, is said to have been born at Berytus in the latter half of the third century. After studying under Pierius at Alexandria, he settled as a presbyter at Cæsarea in Palestine, and began to devote his life to the advancement of Scriptural knowledge. He formed a valuable ecclesiastical library, founded a theological school, and multiplied the copies of the Holy Scriptures. At the same time, all these appliances were used by him with the most liberal-minded philanthropy. All who were animated by a love for sacred learning were kindly welcomed into his library or his school; and all the poor who were eager to read the Divine word for themselves, were presented with a copy of the Bible from his hands. This self-sacrificing life was nobly brought to a close in 309 by a brave endurance of the pains of martyrdom. Pamphilus was the author of an *Apology for Origen*, in five books, a work which was continued by his pupil and admirer Eusebius in a sixth book. The first book alone is extant in a Latin version by Rufinus, and has been inserted in Delarue's edition of Origen.

PAMPHILUS, one of the most distinguished of Greek painters, was born at Amphipolis in the fourth century B.C., and studied at Sicyon under Eupompus. The high opinion which he entertained of the requirements of an artist became the most prominent feature of his career. While studying as a pupil, he thought it necessary to make himself a proficient in all the general learning of the day. After he had succeeded his master as head of the Sicyonian school, he established a comprehensive system of artistic training. All sciences that related either directly or indirectly to painting were included in the subjects of study; the duration of the course was extended over ten years; and the art of delineating was laid down as the fundamental element in the education of all those who were free-born. The result of this thorough-going method soon became palpable. The master and some of his pupils outstripped all other artists in the composition of their pictures; such painters as Apelles were attracted by the growing reputation of the school; and the above-mentioned principle touching delineation came to be adopted throughout the rest of Greece. The close attention which Pamphilus devoted to tuition must have left him little time for the private practice of his art. Accordingly, the only pictures of his whose names are recorded are the "Heraclidæ," "The Battle of Phlius," "Ulysses on the Raft," and the "Cognatio" or "Relationship." The last is supposed to be a family group.

PAMPHYLIA, a province on the S. coast of Asia Minor, was bounded on the N. by Pisidia, on the E. by Cilicia, and on the W. by Lycia and a part of Phrygia. Its limits appear to have never been accurately defined, and to have been different at different times. However, its northern boundary was generally held to be Mount Taurus; and, according to Strabo, it extended from Olbia on the W. to Ptolemais on the E. The inhabitants of Pamphylia, as the name of the country imports, were at first a collection of many different races. These were recruited in course of time by Cilicians and bands of emigrant Greeks. Yet the smallness of the country rendered it unable to play any important part in history. Along with the rest of Asia Minor, it fell successively into the power of the Persians, the Greeks, and the Romans. The principal towns of Pamphylia were Olbia, Attalia (Adalia), Perge, Aspendus, and Side (Eski Adalia); its chief rivers were the Catarrhactes (Duden-Su), Cestrus (Ak-Su), Eurymedon (Kapri-Su), and Melas (Scheher-Su.)

PAMPLONA, a city of Spain, the capital of the province of Navarre, and an episcopal see, in N. Lat. 42. 50., W. Long. 1. 42., 220 miles N.N.E. of Madrid. It is situated in a plain on the left bank of the Arga, closed on three sides by the Pyrenees, and forming what is called the *Cuenca* or bowl of Pamplona. The site is level, except on the N., where there is a descent towards the suburb. Owing to its position, its general climate is cold and humid; heavy snows and rain accompany the N. and N.W. winds in winter, while in summer the S. wind brings excessive heat. The purity of the air, however, and cleanliness of the town, render it tolerably salubrious. Pamplona has always been the frontier key and principal fortress of Navarre, commanding the plains. The fortifications form a rectangle, of which the N.E. and N.W. sides, La Magdalena and La Rochapea, face the river, which has a semicircular bend to the N. about the town. On the S.W. side, La Taconera, stands the citadel, constructed by Philip II. in 1571, after the model of that of Antwerp. It is a pentagon, and is separated from the city by an esplanade. It is calculated to contain 7500 men, but the barracks and store places are in very bad condition. The streets of the town are regular and broad, running generally N.E. and S.W.; and the cleanliness of the town is secured by a system of sewerage superior to anything of the kind in Spain. There are three plazas, of which the principal, De la Constitucion, formerly Del Castillo, has a side of 146 yards, and contains a theatre built in 1843, and the Casa de Diputacion. The plaza is converted on festivals into a Plaza de Toros, and has in the centre a fountain surmounted by a statue. The Plaza de San José contains the cathedral and its residencies. The cathedral, one of the finest in Spain, is a Gothic structure built in 1397 by Carlos III., who is here interred; the previous building, also a re-erection by Don Sancho in 1123, having fallen into ruin, and nothing now remaining of it but a portion of the cloisters. The principal façade is Corinthian, heavy and unsuitable, and was erected in 1783 from the designs of Ventura Rodriguez. Remarkable in the choir are the figures of saints and prophets, of English oak, carved in 1530 by Miguel Ancheta, a native sculptor. There are three parish churches besides that of Saint John Baptist in the cathedral; the church of San Saturnino and that of San Nicolas de Bari are of the twelfth century. There are ten conventual buildings in the town, now mostly devoted to other purposes. There are, besides the citadel, seven buildings for military purposes; four barracks, one in the ancient palace of the kings of Navarre, the others in convents; a military hospital; and a powder magazine. Of places of amusement, there are the theatre already mentioned; two buildings for ball-playing, one of which, El Trinquete, a fine hall with two galleries, is the most frequented; and a fine Plaza de Toros, capable of holding 8000 spectators. The six fountains of the city are supplied by means of a superb aqueduct from Monte Francoa, 2¼ leagues in length, built from the designs of Ventura Rodriguez at the end of last century. This fine work suffered much damage in the last civil war. Pamplona has always been distinguished for its love of letters and attention to public instruction. The institute of secondary instruction has fourteen professors, with good museum and library, and an average attendance of about 300 pupils. It is situated in the Plaza de San José, by the cathedral. The Academy of Design is a fine hall in the lower storey of the Franciscan convent, is supported by the municipal funds, and numbers about 150 pupils, partly gratuitous. There are, besides, a normal school for male and one for female teachers; an infant school; a public boys' school, attended by about 600 pupils; a girls' school, conducted by the nuns of Sta. Catalina de Sena, attended by about 500 pupils, of whom above a third are gratuitous; and several other private establishments. There are three hospitals,—the General Hospital for sick, the Casa de Misericordia, and the Casa de Maternidad, which is also an orphan and a foundling hospital. Of the public gardens and paseos, the finest is that of La Taconera, which is also the most frequented in summer. The district of country near the town is tolerably fertile, producing a considerable quantity of grain and seeds, and the light-red wine called *chacoli*. By the river are many irrigated gardens, from which the town derives most of its vegetables. Besides agriculture, the only branch of industry of any importance is the manufacture of linen. Grain is exported to the mountainous regions of Navarre and Guipúzcoa. The weekly provision markets on Saturday are well supplied, and the market-places are numerous and commodious. The yearly fair, and feast of San Fermin, patron of the city, takes place 29th June to 18th July, and on these days the town is filled with the unusual concourse of people from all parts of the country. The tradition is, that the town was founded by Tubal, A.M. 1840; historically, its foundation is due to Pompey the Great, from whom it derived its name of Pompeiiopolis, now corrupted to Pamplona. It was captured by Euric the Goth in 466, and afterwards by the Franks in 542, under Childebert. Charlemagne dismantled it in 778, in which state it remained till the eleventh century, when the three districts of the town were separately fortified. The continual intestine contests of these three fortresses caused Carlos III., in the beginning of the fifteenth century, to destroy the interior walls, and strengthen the common bulwarks. He also erected the citadel on the site now occupied by the Plaza de Toros and the Basilica de S. Ignacio, built over the spot where that saint was wounded in defence of the citadel against André de Foix in 1521. In the late French war it was taken by stratagem by the French under D'Armagnac, and remained in their power till recaptured after a blockade by Wellington in 1813. In the civil war that followed the death of Ferdinand VII., Pamplona was the strong place of the liberals. The citadel was seized and held for a short time by O'Donnell in September 1841. Pop. (1848) 15,715.

PAN, the god of shepherds among the Greeks, was the son of Mercury, and of a nymph, the daughter of Dryops. He was born a noisy, grinning, hairy infant, fully equipped with horns, a puck-nose, a beard, a tail, and the feet of a goat. As soon as his mother saw her monstrous offspring, she fled from him in horror, and left him to the care of his father. Wrapped up in hare-skins, he was carried by Mercury to Olympus, and was there exhibited to the delighted gods. He was then given out to nymphs to be nursed. The young divinity grew up to be possessed of every rustic accomplishment. His goat-feet could walk lightly and gracefully through the mazes of the dance; his hands could wander nimbly and skilfully over the stops of the pastoral pipe; and his piercing sight, dashing recklessness, and wild lusty halloo, made him the very paragon of hunters. Adorned with all these qualifications, Pan settled down in Arcadia, and undertook the avocations of a rural deity. During his hours of business he protected flocks, bees, and game, and attended to the interests of shepherds, husbandmen, and hunters. A less beneficent part of his employment was to strike sudden fright into large herds of cattle, to startle travellers in lonely places of the forest, and to throw armies into irretrievable rout with a causeless alarm, which was called after him *Panic* terror. In his hours of leisure he took his mid-day slumber in a grotto, practised upon the syrinx, made love to the nymphs, and conducted with dance and song the greenwood merry-makings of the rustic divinities. He would occasionally pay a visit to Bacchus, a god to whom he was always welcome, on account of his loud-ringing voice, and his musical and calisthenic accomplishments. Occasionally also would his fondness for the sea lead him down to the coast to patronize fishing and marine amusements. Pan had many temples

and shrines erected to him in Arcadia. There were also many other places in which his worship was observed. Among these was Athens, where a chapel was dedicated to him in consideration of the aid he had given to the Athenians at the battle of Marathon. His sacrifices were milk and honey. In addition to his best-known character as a god of Arcadia, Pan had also other characters. He was identified with the Faunus of the Romans and the Mendes of the Egyptians. He was also latterly considered as the *universal* god of nature, as the impersonation of the *universe*—τὸ πᾶν.

PANÆNUS, a distinguished Greek painter, was the nephew of the great sculptor Phidias, and flourished at Athens in the fifth century B.C. His principal engagements were of a public nature. He ornamented with painted stories of the gods the Olympian statue of Jupiter which his illustrious uncle had executed. He was also employed to paint with a mixture of saffron and milk the roof of Minerva's temple at Elis. But his masterpiece was the "Battle of Marathon," which constituted one of the decorations of the "Poecile" at Athens. It contained portraits of the Greek leaders Miltiades, Callimachus, and Cynægirus; and of the Persian leaders Datis and Artaphernes. A further peculiarity was, that it represented the fight in four different stages of its progress. In the first the armies were about to engage; in the second they were maintaining an equal contest; in the third the Greeks were beginning to rout their foes; and in the fourth the Persians were escaping in disorder on board their ships.

PANÆTIUS, a celebrated Stoic, was a native of Rhodes, and flourished in the second century B.C. After learning grammar at Pergamum under Crates of Mallus, he settled in Athens as a student of the Stoa. Under Diogenes of Babylon and Antipater of Tarsus, the successive heads of the Stoical school, he rose to eminence and repute. The great Roman, Scipio Æmilianus, became his friend, and chose him for a travelling companion; and the Stoics, on the death of Antipater, elected him for their master. It was in this latter capacity that Panætius established his reputation as an original expounder of the ethical doctrines of his school. He modified the severely abstract maxims of the Stoa into a form more suitable for practical life; supplied their defects from the systems of Aristotle, Xenocrates, Theophrastus, Dicæarchus, and Plato; and clothed them in the fascinating garb of simile and rhetorical ornament. *Rectitude* was defined to be "living in conformity with our natural impulses." The *virtues* were divided into *contemplative* and *active;* and the *useful* and the *honourable* qualities in actions were declared to be coincident. The principal work in which Panætius embodied these principles was a treatise *On Duty* in three books. It is not extant, but its contents have been incorporated in the first two books of Cicero's *De Officiis.*

PANAMA, a town of New Granada, on the southern shore of the isthmus of the same name, stands on a tongue of land projecting into the Bay of Panamá, N. Lat. 8. 57., W. Long. 79. 30. The plan of the town possesses some regularity, but is not entirely uniform; the principal streets extend across the peninsula on which it is built. The streets are better cleaned than in most of the Spanish towns in America. It is for the most part substantially built in the old Spanish style, and all the larger houses have interior courts, or *patios,* as they are called. The chief public edifices are—an elegant cathedral, several convents, a nunnery, and a college. The fortifications of the town consist of high walls and irregularly-constructed bastions, which have been added at various times, as the protection of the place required. The harbour of Panamá is sheltered by several islands at some distance from the land. These form one of the finest roadsteads in the world, with very safe anchorage. The trade of the place is very considerable, and is likely to be much increased by the railway which has been recently constructed between this place and Aspinwall, on the Atlantic shore of the isthmus, although the immediate effect of this improvement has been to reduce the importance of Panamá in comparison with Aspinwall. Quinine bark, cacao, India-rubber, hides, pearl oysters, and other articles, are exported from hence to Europe; and it is expected that most of the trade formerly carried on round Cape Horn will now pass through Panamá. The town was originally built by the Spaniards, on a spot about 3 miles to the east of the modern town; but it was burned down in 1670 by Sir Henry Morgan, the bucaneer, and afterwards rebuilt in its present position. Pop. 6000.

PANAMA, or DARIEN, *Isthmus of,* connects the continents of North and South America, and forms a state of the republic of New Granada. Its shape is that of an arc of a circle, curving towards the N., and inclosing the Bay of Panamá on the S. Both sides of the isthmus are indented by several creeks and harbours, of which the most important are Port Escoces and Navy Bay on the N., and the harbours of Panamá and San Miguel on the S. The interior of the isthmus is little known. Part of it is occupied by the Cordillera, or great mountain chain which extends through the American continent; but this mountainous region is interrupted by tracts of low level ground. These plains are well watered, thickly wooded, and rich in minerals and the vegetable produce of tropical countries. Besides the railway from Aspinwall to Panamá, a canal has been proposed from Port Escoces to San Miguel. The breadth of the isthmus varies from 30 to 70 miles, being narrowest at Panamá. The chief river of Panamá is the Chagres, which flows first westward, then northward, and falls into the Atlantic, after a course of 80 or 90 miles, for 44 of which it is navigable by barges. Before the construction of the railway it was of much importance, as goods were conveyed by it part of the distance across the isthmus; and the town of Chagres, at its mouth, was the chief port on the north side of Panamá. This was, however, at best a wretchedly-built and very unhealthy place, with a shallow and unsheltered harbour, and is now quite deserted, having been supplanted by the new town of Aspinwall on Navy Bay. Pop. of the state of Panamá, 138,108.

PANAON, a small island in the Philippine group, lies between those of Leyte and Mindanao, N. Lat. 9. 55., E. Long. 125. 8. Its length is about 18 miles, and its circumference 45 miles. There are several small rivers in the island.

PANATHENÆA (Παναθήναια), an ancient Athenian festival in honour of Athena, the protectress of Athens. Harpocration and Suidas refer the institution of this festival to Erichthonius IV., King of Athens, who lived before Theseus. Theodoret alone says that the feast was established by Orpheus. But be this as it may, till the time of Theseus it was never a particular feast of the city of Athens, and was simply called *Athenæa;* that prince, however, having united all the people of Attica into one republic, they afterwards assisted at the festival; and hence the name *Panathenæa,* or the feast of all Attica. In effect, all Attica was present; and each division of the people sent a bullock for the sacrifices, and for the entertainment of the vast multitude of people assembled. There were two festivals under this denomination, the greater and the lesser. The greater Panathenæa were celebrated in the third year of each Olympiad, probably on the 28th of Hecatombæon; the less, annually. Though the celebration of neither employed at first more than one day, yet in after times they were protracted for the space of many days, and solemnized with greater preparations and magnificence than at their first institution. The ceremonies were the same in the greater and the lesser Panathenæa, excepting a banner, on

which the actions of the goddess were represented in embroidery, executed by maids, with the names of those who had distinguished themselves in the service of the republic. This only was borne at the greater. Prizes were established for three different kinds of combat. The first consisted of foot and horse races; the second, of athletic exercises; and the third, of poetical and musical contests. These last are said to have been instituted by Pericles. Singers of the first class, accompanied by performers on the flute and the cithara, exercised their talents upon subjects prescribed by the directors of these exhibitions. (See Meursius, *Panath.*, Lugd. Bat. 1619; H. A. Muller, *Panath.*, Bonn, 1837; K. O. Muller, in *Phil. Museum*, vol. ii., p. 227, &c.)

PANAULON, an enlarged German-flute, with sixteen finger-keys, and descending as low as G in the treble clef, with two ledger lines under the stave. It was invented some years ago by Trexler of Vienna. To remedy its inconvenient length, the lower end was curved. The quality of its tone is not so good as that of the common German-flute; but still the panaulon may be effectively used in orchestra music as a bass to the other flutes.

PANAY, the central island of the Philippines, lies between N. Lat. 10. 25. and 11. 50., E. Long. 122. and 123. 10., having Mindoro on the N.W., Masbate on the N.E., and Negros on the S.E. Its form is triangular; its length, 110 miles; breadth, 100 miles; area, about 4579 square miles. The surface is mountainous, especially in the N.E. and S.W.; but it is well watered, and has a fertile soil. Along the western coast there is a low, well-cultivated tract of ground, containing several villages and a large population. Rice, maize, sugar, tobacco, coffee, and other crops are raised on the island; and in the interior there are extensive forests of valuable timber. Buffaloes, wild oxen, stags, &c., abound, as well as birds of great beauty. Turtle and fish are obtained on the shores and in the rivers. The women are chiefly employed in weaving; while the men work at agriculture, fishing, cutting wood, making oil and sugar, &c. The island is divided into the provinces of Iloilo, Capiz, and Antique. Iloilo, the chief town, has a harbour capable of affording safe anchorage to a large number of vessels. Many coasting ships frequent it, and some commerce is carried on. The resources of the island are such as to lead to the expectation of its making rapid progress and attaining great prosperity. Pop. 559,861.

PANCRAS, St., a parish of England, in the county of Middlesex, forming a part of London towards the north. The church of St Pancras in the Fields contains many interesting monuments. There is also a new church, which is a fine specimen of the Athenian-Ionic style of architecture. Area of the parish, 2716 acres. Pop. (1851) 166,956.

PANCRATIUM (compounded of πᾶν, *all*, and κρατος, *strength*) signifies properly an athletic game in which all the powers of the athlete were brought into play. It consisted of wrestling and boxing; but the athletes were not permitted to seize the body, and their hands were not armed with gauntlets. The *pancratium* was the third and the most severe of all the gymnastic exercises of Greece, and was not introduced till long after the others. The people who were engaged in these exercises were called *pancratiastæ*,—a name which was also given to such as did not confine themselves to one exercise, but succeeded in several different ones. (See J. H. Krause, *Die Gym. und Agon. der Hellenen*, vol. i.)

PANCSOVA, a town of the Austrian empire, in the Banat Military Frontier, stands on the Temes near its junction with the Danube, 8 miles E.N.E. of Belgrade. It contains a Roman Catholic and a Greek church, and two schools. Many of the houses are well built, and inhabited by Germans and Greek merchants. Manufactures of beet-root sugar and of silk are carried on; and there is an active trade in corn, timber, and cattle. Pop. (1851), exclusive of the military, 11,043.

PANDECTS. See CIVIL LAW.

PANDORA (from πᾶν, *every*, and δῶρον, *a gift*), a personage who is represented in classical mythology as the first mortal woman. The following account is her history, as given by Hesiod:—Jupiter, enraged at Prometheus for having stolen fire from heaven, resolved to send upon the earth some great evil under a lovely and bewitching disguise Vulcan was accordingly commanded to create out of clay a female possessing the form and features of an immortal goddess. The divinities of Olympus were then summoned to adorn the new being with their gifts. Venus breathed upon her grace and beauty, Mercury instilled into her mind insinuating and impudent artifices, Minerva taught her domestic accomplishments and clothed her with becoming garments, and the Hours and Graces decked her with golden necklaces and crowned her with flowering chaplets. Thus adorned, as the name then given to her implied, with *all the gifts* of the gods, Pandora was sent by the hand of Mercury to Epimetheus, the brother of Prometheus. That infatuated individual, although warned beforehand, accepted the fascinating present, and entailed perpetual misery upon the human race. In a short time, a peculiar vase came under the inquisitive eye of the woman; her hand was tempted to open it; a swarm of plagues, privations, and miseries hitherto kept imprisoned, immediately flew forth to haunt the world for ever; and Hope alone remained at the bottom.

PANEEPUT, a town of British India, capital of a district of the same name in the territorial division of Delhi, N.W. Provinces, stands in a fertile country, 78 miles N. of Delhi, and 965 N.W. of Calcutta. The numerous white spires and domes of the various temples render Paneeput a beautiful object when seen from a distance. Most of the houses are built of brick, and are provided with balconies. The walls and ramparts, with which the town is surrounded, are of an irregular kind, having been built at several different periods. There are here two caravanserais, which contribute greatly to the importance of the town. In the vicinity there are a great number of tombs in ruins, and many of these are remarkable for size and splendour. The neighbourhood of Paneeput, lying in the great military highway between Eastern India and Afghanistan, has been more than once the field of great battles. Here, in 1526, Baber gained the victory over the Patan King of Delhi, which overthrew that dynasty; and here, in 1761, the Mahrattas were conquered by the Afghans under Ahmed Shah. Pop. (1853) 22,612.

PANEEPUT, a district of British India, in the division of Delhi, bounded on the N. and W. by the division of Sirhind, S. by the district of Delhi, and E. by those of Meerut and Mozuffurnuggur. It lies between N. Lat. 28. 50. and 29. 48., E. Long. 76. 40. and 77. 16., having a length of 65 miles from N. to S., a breadth of 30 miles, and an area of 1279 square miles. The surface is flat, and well watered by natural streams and by artificial canals; but in many parts it is quite barren, and covered with a saline incrustation resembling snow in its appearance. The principal river is the Jumna, which flows along the eastern boundary of the district. Pop. (1853) 389,085.

PANEGYRIC (πανήγυρις), an oration in praise of some extraordinary person or thing. The name is composed of πᾶν, *all*, and ἀγειρω, *I assemble*; because anciently in public and solemn assemblies of the Greeks, either at their games, feasts, fairs, or religious meetings, panegyrics were pronounced. To render these the more solemn, the Greeks used to begin with the praises of the deity in whose honour the games were celebrated; next they descended to the praise of the people or country where they were celebrated; then they

Panel || Pannonia.

lauded the princes or magistrates who presided at them; and, lastly, they bestowed eulogies on the champions, especially the conquerors, who had gained the prizes in them.

PANEL, according to Sir Edward Coke, is derived from *pane*, a part, and denotes "a little part;" but the learned Spelman says that it signifies *schedula vel pagina*, a schedule or roll, as a panel of parchment, or a counterpane of an indenture; whilst others derive it from the French *panne*, a skin. It is used more particularly for a schedule or roll, containing the names of such jurors as the sheriff returns to pass upon any trial. Hence the *impanelling* a jury is the entering their names in a panel or little schedule of parchment.

PANIONIA, a great national festival of all the Ionians, celebrated on Mount Mycale, in honour of Poseidon, their national deity. In this festival, if the bull offered in sacrifice happened to bellow, it was accounted an omen of divine favour, because that sound was thought to be acceptable to the god. These national gatherings were frequently political as well as religious.

PANMELODICON, an instrument invented by Leppich at Vienna in 1810. By means of a conical barrel moved by a wheel, rods of metal, bent to a right angle, were made to sound when the finger-keys were pressed down.

PANNINI, GIOVANNI PAOLO, an eminent Italian painter, was born at Piacenza in 1691. At Rome, where he completed his preparatory studies, he devoted his attention chiefly to the painting of architecture, and acquired great excellence in that branch of art. Although prone to make his figures too large in proportion to the buildings, and to fall into the mannerism of mixing a reddish hue in his shadows, he was unsurpassed in his management of perspective. His groups of figures were also admirable for their grace, variety, and vivacity. All these qualities were displayed with especial advantage in his picture of the "Money-Changers driven from the Temple." Pannini died in 1764.

PANNONIA, a Roman province, was bounded on the W. by Noricum and Italy, on the S. by Illyricum and Mœsia, and on the E. and N. by the Danube, and corresponded to that track including Croatia, Slavonia, and portions of Austria, Hungary, and Bosnia. The early history of the country is involved in obscurity. Some suppose that its original inhabitants were Pæonians, who gradually came to call themselves Pannonians. A more probable opinion is, that it was colonized by Celtic tribes. At any rate, in 35 B.C. the Romans found the district in a low state of civilization. The extensive forests which cumbered the soil prevented the pursuits of agriculture; and the natives, divided into several tribes, which seem to have acknowledged separate chiefs, were addicted to war and rapine. From that date, however, a change slowly began to come over the social state and government of Pannonia. In 8 A.D., after an obstinate resistance, it was ultimately subjugated and reduced to the form of a Roman province by Tiberius. In the second century it was divided into two parts, Upper Pannonia, on the W., and Lower Pannonia, on the E. In the third and fourth centuries the emperors Probus and Galerius cleared the soil of much of the wood, and made room for the operations of agriculture. Meanwhile roads had been made, colonies had been planted, and Roman legions in the various fortresses, and a Roman fleet on the Danube, protected the government of the country. Pannonia retained this social organization until the middle of the fifth century, when it was ceded to the Huns.

The most important towns in Lower Pannonia were—Vindobona (*Vienna*), Carnuntum, Sabaria (*Sarwar*), Æmona (*Laybach*), and Siscia (*Siszeg*). Those in Upper Pannonia were Acincum (*Alt-Buda*), Mursa (*Erzek*), and Sirmium. The principal rivers were the Arrabo (*Raab*), the Dravus (*Drave*), and the Savus (*Save*), all flowing into the Danube.

Panorama.

PANORAMA (from πᾶν, *all*, and ὅραμα, *a view*) is a picture drawn on the interior surface of a large cylinder, representing the objects that can be seen from one station, when the observer directs his eye successively to every point of the horizon. A picture drawn on a vertical plane in the usual way includes only that portion of the sphere of vision that can be seen from one point opposite to the picture, without turning the eye; this portion may comprehend about thirty degrees of the horizon, because the field of distinct vision when the eye remains unmoved is concluded in a cone, the angle at the apex of which does not exceed thirty degrees. There are compositions comprehending the visible hemisphere, and sometimes nearly the whole sphere of vision; and in these, one connected scene is represented on the interior surfaces of a polyhedron or of a curved solid, the point of sight being in the centre of the polyhedron, and the eye being turned round on its centre to each of its surfaces, in order to view the whole scene. Of this kind are the gnomonic projection of the sphere on the interior surfaces of a cube, and several pictures, in which one connected subject is represented on the ceiling and the sides of a room; such as the picture of "Jupiter Fulminating the Giants," by Giulio Romano, on the walls and hemispherical ceiling of a round room in the Palazzo del T at Mantua; and the architectural representations and ornaments in Raphael's Loggie in the Vatican. Objects are also sometimes projected on the interior surface of a sphere, the eye being placed in the centre; as in a large hollow sphere with the constellations, which was constructed at Pembroke College, Cambridge. These projections, where the eye, remaining in the point of sight, is turned round on its centre to view the different parts of the picture, are formed on the same principle as the panorama.

The cylindrical surface is the most convenient for panoramas of landscapes; and the specific employment of a large cylindrical surface for representing the landscape of the whole circle of the horizon is the invention of Robert Barker, who brought the panorama into use about the year 1794. The cylinder on which the panorama is painted is commonly about sixty feet in diameter. The projection or perspective of a panorama is formed by imaginary lines drawn from different points of the surrounding objects to the point of sight in the axis of the cylinder. The intersections of these lines with the cylindrical surface form the corresponding points in the panoramic picture. Where the picture is projected on a plane, as in common perspective, and in the gnomonic projection of the sphere, the cones formed by imaginary lines or rays passing from the point of sight to the different objects are cut by the plane of the picture; consequently the sections, being formed by a plane, are curves of which the curvature is always simple. In the perspective of the panorama, where the picture consists of the intersection of the cones of rays by a cylinder, these intersections are, in many of the cases, doubly curved curves. When the picture of a straight line which is neither parallel to the horizon nor to the axis of the cylinder is drawn on the cylinder of the panorama, the picture of the line is part of an ellipse, because the oblique section of a right cylinder, by a plane passing through the axis, is an ellipse; when the cylinder is developed and unrolled on a plane surface, this ellipse becomes the curve called the sinical curve. The projection of lines on the interior surface of a cylinder is also employed in drawing Mercator's charts. But in the projection of the panorama, the field extends only a few degrees above and below the horizon, whereas in the projections of the sphere, the field extends many degrees on each side of the plane, which is at right

Panormus || Pantheism.

angles to the axis of the cylinder. In drawing a panorama, as well as in drawing a picture on a plane, the horizontal angles between different objects may be observed by a plane table or theodolite; and the elevation of the objects above the horizon, or their depression, may also be observed by the theodolite. The horizontal angles are to be laid down by setting off on the graduated horizon of the cylindrical picture the number of the degrees observed; the vertical angles on the cylinder are the tangents of the angles observed, the radius being the semidiameter of the cylinder.

PANORMUS. See PALERMO.

PANTALONE, an instrument invented about the end of the seventeenth century by Hebenstreit, a German. It resembled the German psaltery, was of an oblong shape, and had two sound-boards, the one furnished with metal wires, the other with gut-strings. Its compass was the same as that of the harpsichord.

Pantellaria || Pantheism.

PANTELLARIA (anciently *Cossyra*), an island belonging to Sicily, in the Mediterranean, 50 miles E.S.E. of Cape Bon, and 80 miles S.W. of the coast of Sicily. The coasts are steep and rocky, affording a landing-place only in one harbour; and the surface is mountainous, and of volcanic origin. It contains mineral springs, and a lake of great depth. The soil is fertile, producing vines, figs, &c. The principal town, which is called Pantellaria, and sometimes also Oppidolo, is built in the form of a semicircle round the harbour, which has a narrow entrance. It contains several churches; and is defended by a castle occupied by a Sicilian garrison. Pop. of the island, 7000.

PANTHEISM.

Description of Pantheism.

PANTHEISM (πᾶν, *all*, Θεός, *God*), is that speculative system which, by absolutely identifying the Subject and Object of thought, reduces all existence, mental and material, to phenomenal modifications of one eternal, self-existent Substance, which is called by the name of God.

The rational solutions of the problem of existence hitherto proposed reduce themselves to the two great classes of Dualism and Unitarianism. The former divides being or substance between two original principles, the latter limits it to one. Three possible ontological theories emerge from Unitarianism, according as we identify absolute reality with Self, with the World, or with Deity:—1. Are all things educed from, and identified with, Self? *Egoism* emerges, of which the corollary is properly Atheism. 2. Are all things educed from, and identified with, Matter? *Materialism* emerges, of which the corollary is also properly Atheism. 3. Are all things educed from, and identified with, Deity? *Pantheism* emerges, which is subject to two grand subdivisions, according as He is conceived of as exhausted or as unexhausted in the act of producing the universe. 1°. Is he regarded as exhausted in the act? Material, physical, real Pantheism is the result, which is subject to further modifications, and of which the proper formula is, *All things are God, and God is all things.* 2°. Is he regarded as unexhausted in the act? Spiritual, ideal, intellectual Pantheism is the result, admitting also of further modifications, and of which the proper formula is, *All things are God, but God is not all things.* According to the former scheme, the one necessary eternal being is identified with the universe, the progressive evolution of material nature being regarded as the development and adequate expression of the entire Divine existence; by the latter scheme, the universe is regarded as a necessary yet inexhaustive evolution of Infinite Being, of which it forms an essential part.

Speculative origin of Pantheism.

As pantheistic speculation finds its origin in that intellectual ambition which would aspire to universal knowledge, and would rest satisfied only with the personal subjugation of the empire of being, it is not to be supposed that it should be limited in its development to any particular time, age, or country. The peculiar class of thinkers likely to be determined towards pantheism are found to rise up in almost all times and in nearly all places.[1] The humble walks of sober induction are discarded as beneath the notice of a lofty and daring genius bent upon the achievement of all knowledge and the conquest of all existence; a position of the highest abstraction is assumed, properly indeterminate and absolutely general, from which, without any regard to what knowledge or existence really is, it becomes the task of the formal ontologist to *deduce* the particular and determinate of knowledge and existence. But neither boldness of design nor brilliancy of execution can atone either to philosophy or to humanity for the essential error and dangerous results which are invariably attendant upon all such attempts to transgress the fixed boundaries which One wiser than we has assigned to our intellectual operations. Such frequent attempts, however, and such conspicuous failures, bring with them their lesson of wisdom. And this lesson may surely be read in the history of pantheistic speculation.

Historical origin of Pantheism.

The origin of pantheistic philosophy can be traced back to near the dawn of reflection in the remote East; and among no class of thinkers has this speculative system found more favour, or a more constant advocacy, than among the dreamy and subtle Orientals. In the front rank stands India, that great centre of speculative activity in the East, which has given birth to pantheistic systems as vast and various as the country on whose soil they grew. Not that speculative systems of rigid scientific strictness, or of an exclusively philosophical character, are to be found among the schools of the Hindus, so far as they are yet known to Europeans. For, with all that has been admiringly said regarding the scientific grandeur and completeness of the Hindu systems of philosophy, we always find, on coming into actual contact with them, that, pervaded as they are by marvellous acuteness, they nevertheless, from their semi-religious, semi-poetical character and colouring, fail to satisfy the demands of rigid scientific speculation both in connected severity of thought and in clear accuracy of expression. This may no doubt in some measure arise from our imperfect acquaintance with their systems; but it is beyond a doubt, that those who fling the pantheistic speculations of the Hindus as a triumphant taunt in the face of Spinozism, as if all that the subtle Jew had accomplished had been often and better done before, do so either in ignorance or through sheer wantonness. For there can be no question whatever, that, so far as history informs us, no pantheistic theory has ever been forged by the brain of man so complete in conception and masterly in execution as that elaborated by Spinoza. In point of fact, however, Spinoza, with all his iron logic and severity of system, never rises to heights more purely pantheistic than are to be found among the mystical speculations of the Hindus. The main distinction is, that the Orientals vivify their philosophy with a spirit of religion, and clothe it with a garniture of poetry; while, with the western pantheist, speculation is a matter almost entirely of the intellect, and no extraneous consideration whatever, apart

[1] "Pantheistic tendencies are found," says H. Ritter, "wherever religion and philosophy are to be found, even among the islanders of the South Sea." (*Hist. of Anc. Philosophy*, vol. i., "Origin of Greek Philosophy.")

from the direct, undeviating path of a rigorous logic, finds any place in the system of this stern thinker.

Hindu Pantheism.

The Hindus themselves reckon six different schools of Indian philosophy, all regarded as offshoots from the primordial doctrines of the Brahmans or sacerdotal caste, viz.,—1. The *Sankhya*, attributed to Kapila; 2. The *Yoga* schools of Pantanjali and the *Bhagavad-Gítá;* 3. The *Púrva-Mimansa*, attributed to Jaimini; 4. The *Vedánta*, or *Uttara-Mimansa*, by the Vyása[1] Krishna Dwaipayana; 5. *Nyaya*, of Gautama; 6. The *Vaisheshika*, of Kanâda.[2] The doctrines of these six schools, however, may be conveniently included under the three general systems denominated the *Sankhya* (including Nos. 1 and 2), the *Nyaya* (including 5 and 6), and the *Vedic* system (including 3 and 4). Curious to say, the only one of these schools considered by the Hindus to be orthodox or conformable to the doctrine of the Vedas, or sacred books, is the Púrva-Mimansa, which is more a Brahmanical essay on the Vedas, of very indifferent merit, than a regular treatise on philosophy.[3] The Sankhya system exhibits a twofold development,—the one atheistic, by Kapila; the other theistic, by Pantanjali. Both agree, however, in being dualistic, admitting, as they do, two real and substantial principles,—Material Nature and the Human Soul,—and are thus excluded from present consideration. The system termed the Nyaya is properly a scheme of logic, at once complicated and elaborate, followed up by a complemental theory of the physical world. It is to the system termed Vedic, accordingly, that we have to direct our attention.[4]

The Vedanta philosophy is the very incarnation of pantheism; and there can be no conceivable ramification of that system which does not find a place among the complicated subtleties of this singular body of doctrines. The great end of man's life, according to this philosophy, is to free himself from all vicissitude, and to attain to perfect repose. This can only be achieved by disengaging himself from that which is transient, and by attaching himself to that which is fixed, eternal, and absolute. Only two paths are open to such a deliverance,—science and good works; and but one of them leads to the golden gates of silence and rest. Good works, as transient in their nature, can only produce a corresponding degree of satisfaction; but science, as devoted to the contemplation of the supreme unity, which is subject to no change, can elevate man above all vicissitude, and secure for him enduring satisfaction.[5] But how is such a consummation to be achieved? Sense cannot attain this science, for it has to do with the transitory; reasoning is likewise insufficient, for the discursive faculty, as essentially relative, can never become the measure of the absolute. To attain to immutable being, accordingly, it is necessary to approach it through that revelation which has been preserved in all ages by the divinely initiated. Sense must be ignored, and all desire for the temporal and earthly must be completely foregone. The aspirant to science must become absorbed in pious meditation, must forget his own individuality, and make the object of his contemplation the Supreme Existence,—the great end of life being not "the union of Self with Supreme Spirit," but to know that all is unity. "Best of all is the *identification* of Soul with the Supreme Spirit."[6] The novice can then have the mysteries of science disclosed to him; and the sum of the revelation is contained in the formula—*All is soul; Brahma* (or Deity) *alone exists; everything else is an illusion.*[7] "Listen to the complete compendium of the Purânas, according to its tenor. The world was produced from Vishnu:[8] it exists in him: he is the cause of its continuance and cessation: *he is the world.*"[9] Having reached this sublime abstraction, the Vedantists labour to give validity to it by considerations drawn from the very idea of Brahma. If there existed out of Brahma, who is the one eternal, absolute, unlimited being, existences, limited, manifold, complex, they must have been produced by him. But as they are repugnant to his very essence, it would be impossible for Brahma to produce them, unless he possessed within himself the real source of limitation, multiplicity, and imperfection. It accordingly follows, continue these speculators, that the mind of man stands in a twofold relation to the universe,—the one resembling a state of sleep or dreaming, the other that of being awake. In the former state man realizes phantasms only, and hence regards the multiplicity of beings in the universe as distinct from Brahma; but when he rises to the waking state, these phantoms of the brain vanish before the coming light of science, and he at once recognises Brahma as everything, and addresses him as "Thou All!"[10] Mind and Matter, in their mutual antithesis and reality, are here of course destroyed. All particular beings, whether spiritual or material, are not even simple modifications of the Divine substance in the same sense in which they are regarded in some systems of pantheism; the universe, material and mental, is nothing but the spectacle of the thoughts of Deity, which he represents to himself by contemplating their possible combinations if realized out of himself. For the law of Causality, which exists in every mind, the refining Hindu substitutes the doctrine of Emanation; and thus discovers, by quite irrefragable logic, that what we call Matter is a mere illusion, and Mind but an empty dream. Corresponding with these two conditions of human thought and life, there exists in the Vedantist philosophy two separate languages,—the one, that of illusion; the other, that of science. The one language is expressive of the relative and the apparent, the other of the absolute and the real. Parallel series of propositions are thus to be found in this philosophy which are apparently contradictory and mutu-

[1] This Vyása (compiler) is generally written and spoken of in most books of philosophy as if it were a proper name, whereas it is used here emphatically to distinguish the last of the 28 vyásas or compilers, who are generally regarded as the redactors of the Vedas. (See *The Bhagavad-Gítá, a Sanskrit philosophical poem*, translated by J. C. Thomson, 1855, p. 69, note.)

[2] See Weber's *Vorlesungen ueber die Indische Literatur-Geschichte*, Berlin, 1852.

[3] For an account of the numerous philosophical sects among the Hindus, see Colebrooke's *Miscellaneous Essays*, vol. i., "Indian Sectaries;" also H. H. Wilson's Essays in the *Asiatic Researches*, vols. xvi. and xvii.

[4] The compilation of the Vedas remounts, according to Colebrooke, to the fourteenth century B.C., and according to Sir Wm. Jones, to the sixteenth B.C.; while Ritter is emphatic in his rejection of the pretensions of the Hindu philosophy to a high antiquity. But on this whole matter critical philosophers and oriental scholars seem alike at sea.

[5] "The great end of life (or truth) is considered by the wise to be eternal; but it would be transient if it were accomplished through transitory things. If you imagine that this great truth is the performance of religious acts, from which no recompense is sought, it is not so; for such acts are the means of obtaining liberation, and truth is (the end) not the means." (See Wilson's *Vishnu-Purânas*, p. 252.)

[6] *Vishnu-Purânas*, chap. xiv.

[7] "The knowledge that this spirit, which is essentially one, is one's own, and in all other bodies is the great end or true wisdom of one who knows the unity and true principles of things. As one diffusive air, passing through the perforations of a flute, is distinguished as the notes of the scale, so the nature of the great spirit is single, though its forms be manifold, arising from the consequence of acts." (*Vishnu-Purânas*, c. xiv., p. 253.)

[8] The Supreme Being of the Hindus is regarded under the three relations of Brahma, Vishnu, and Shiva. Of this Trinity, Brahma is the creator, Vishnu the preserver, and Shiva the destroyer and renovator of material forms.

[9] *Vishnu-Purânas*, c. i., p. 6.

[10] See Cockburn Thomson's *Bhagavad-Gítá*, c. xi.

Pantheism.

ally destructive of each other. But the Vedantist reminds us that there are radically two orders of things,—the real and the illusory. He omits, however, to tell us how this asserted illusion can arise out of the pure and absolute essence of the unconditioned Brahma. To any intelligence but that of a Vedantist it is no doubt palpably contradictory and absurd. Real or imaginary, contradictory or otherwise, this alleged state of illusion is a state of bondage, suffering, and error; but once free from it, the emancipated thinker is no longer perplexed with distinctions, and forms, and names; there is for him then no distinction, no name, no form; there is but one absolute substance, in which the subject and object of thought are absolutely identical.

The Vedantist neophyte having passed through this speculative novitiate, begins to reap the fruit of his vigils. The practical tendencies of the system here emerge, and in them we find, boldly and consistently conceived, and no less boldly and consistently advocated, the normal tendencies of pantheism in their relation to human duty. When man has attained to this superior knowledge of the Vedantist, he is emancipated from all ignorance, and can know no error: from ignorance, for in affirming Brahma, he affirms everything; and from error, since he has annihilated the possibility of error, which implies a particular affirmation, in annihilating the distinction of beings. He is not responsible, and can commit no sin; for such conceptions, as implying a right and a wrong, suppose distinction, which belongs to the state of illusion, but can find no place in Brahma, where all diversity ceases. He is freed, besides, from all activity, which supposes a duality,—a subject and object of action,—the very negation of that absolute unity and identity of all things which his science has taught him. He feels no emotion and is prompted by no desire, for he knows that, in being Brahma, he possesses everything. During life, the soul of the wise man continues, despite his knowledge of Brahma, to be haunted by recollections of the phantoms which flit through the realms of illusion, just as the awakened sleeper remembers the incidents of his dreams; but when death comes, the emancipation is complete,—the sage is stripped of every vestige of individuality,—he can show no longer any trace of limitation,—in form and in name he is mingled with and lost in Brahma, as rivers lose their forms and names when they meet the ocean. Such, in brief, is the pantheism of the Vedic schools of the Hindus.[1]

Other forms of speculative error, frequently spoken of as pantheistic, exist among the Buddhists, the great opposing sect of the Brahmans in the religion and philosophy of the Hindus. But while these systems are heterodox and unitarian, they are nevertheless not properly pantheistic. They oscillate between materialism and idealism, and one of the schemes is so refined as to end in sheer *egoism*, such as that of Fichte in Germany, admitting of no real existence but that of Self or the Ego, which is alleged to be eternal, and to draw from its own depths all phenomena.[2] Such a system is properly atheistic.

Greek Pantheism.

In further tracing the historical evolutions of pantheistic speculation, we find ourselves at once transplanted from India to Greece; for while the philosophical systems developed in China, in Persia, in Egypt, in Chaldæa, and in Phœnicia, were as false as they were various, they nevertheless exhibit no instances of speculative theories legitimately pantheistic. And without waiting to consider the vexed question of how much Greece owed to the philosophical ideas of the East, it is sufficient here briefly to ascertain the precise character of Greek speculation in itself, irrespective of its peculiar genesis, which is at best extremely problematical.[3] It is but a shallow view of the history of human development in matters of speculation that would ascribe every similarity of doctrine or coincidence of thought to direct filiation; for a comparatively limited knowledge of the struggles of individual minds towards scientific insight will not only warrant the possibility of something more than even a general resemblance in the speculative efforts of independent thinkers, but will positively lead the inquirer to anticipate the independent recurrence of the same methods, ideas, and sympathies, in places the most distant and in times the most remote. It is not necessary, therefore, apart from direct evidence, to ascribe to a Hindu source, as is often done, every possible vestige of the pantheistic theory recorded in the annals of philosophy. Pantheism, if a great speculative error, is at least not an unnatural one for erring men, as both history and observation can attest; not unnatural either for Brahman or Greek, Jew or German.

Anaximander.

Passing over as dualistic the earliest speculative evolution of the Ionic school, with which began properly the history of Greek thought, and the adherents of which followed what has been called the "physical" method of investigation, we approach the second development of Ionian philosophy in the class called "mathematicians," which originated with Anaximander[4] of Miletus (611–547 B.C.), the father of the pantheistic tendencies of Grecian speculation. With him began the purely *deductive* method of philosophizing afterwards employed by the Pythagoreans and Eleatics; and consequently, also, with him began the disposition to develop the universe from one grand indeterminate abstraction. The beginning of things (ἡ ἀρχή), according to this geometrician, was not Water, as Thales had supposed, but the Infinite (τὸ ἄπειρον). This Infinite or primary existence is One, yet All. Finite things, of whatever kind, are but the manifestations of this eternal unlimited All. Creation takes place by an eternal motion of the Infinite. It does not seem, however, that Anaximander identified this Infinite Existence with Infinite Mind, much less that he called it by the name of Deity. To all intents and purposes, however, his grand error was identical with that of Hegel and his school in modern times, who maintain that "creation is the mundane existence of God." The direct pantheistic conception of Deity was posterior to the time of Anaximander.

Pythagoras.

Pythagoras (584–489 B.C.), the first among scientific thinkers who called himself by the humble yet exalted title of "philosopher," took up the method of Anaximander, and endeavoured to improve upon his notion of the ἀρχή. Like his predecessor, Pythagoras held the principle of things to be absolute unity, from which multiplicity origi-

[1] See *De Theologumenis Vedanticorum*, by K. J. H. Windischmann, Bonn, 1833; also Windischmann's *Die Philosophie im Fortgange der Weltgeschichte*; and Ritter's *History of Ancient Philosophy*, vol. iv, London, 1846.

[2] The author of the *Précis de l'Histoire de la Philosophie* (known to English readers as Henry's *History of Philosophy*) falls into the mistake of reckoning Egoism a species of Pantheism. In the *Essai sur l'Pantheisme dans les Sociétés Modernes*, par H. L. C. Maret, troisième edition, Paris, 1845, p. 176, the rhetorical Abbé falls into a similar mistake respecting Fichte, who is erroneously ranked by him among the pantheists. This is a blunder, however, which is by no means peculiar to this churchman, for numerous writers,—and especially English ones,—have committed the same error.

[3] The Greeks themselves admitted their obligations to the oriental philosophers. Among others, Ritter (*Hist. of Anc Phil.*, vol. i.) and Lewes (*Biographical Hist. of Philosophy*, Introd. to the library edition; also *Edinburgh Review*, April, 1847), are tolerably decided,—the former particularly so,—as to the independent origin of Greek speculation; while the modern orientalists, Roth (*Geschichte unserer abendländischen Philosophie*, vol. i.) and Gladisch (*Die Relig. u. die Phil. in ihrer weltgesch. Entwickelung.*) find nothing in the early Greek teachers but reproductions of eastern thought.

[4] Let it be noted here, once for all, that biographies of the philosophers alluded to in this article will be found under the name of each throughout the work.

Pantheism.

nated, and of which it was but the manifestation. This original principle was Number, and the absolute unity was One. As One is the basis of all numerical calculation, so also it is the last expression of our attempt to analyse the Infinite. Therefore the Infinite must be One; and Numbers are the ultimate nature of things. The Pythagoreans did not separate Numbers from things. "They held Numbers," says Aristotle, "to be the first principle, and, as it were, the material cause (ὕλη) of entities, as well as of their peculiar manifestations." (*Metaph.*, b. i., c. 5.) As to the precise significance which Numbers bore in the theory of Pythagoras critics are not agreed. Some are inclined to a literal, some to a symbolical interpretation of the term.[1] However this may be, suffice it to say, that by reducing mind and matter to phenomenal manifestations of the infinite and absolute One, he thereby constructed a scheme essentially pantheistic. It remains doubtful, however, as in the case of his predecessor, whether or not he made mind an attribute of his Infinite One. To reason from the spurious and notoriously pantheistic works ascribed to his followers, Timæus of Locrum, and Ocellus Lucanus, and thus convict the master of a pantheism which he did not in terms avow, would be at once futile and foolish. Suffice it to say, pantheism was there in substance, if not in name.

Xenophanes.

Not content with the solution which the great problem of existence had received at the hands of the "mathematicians," Xenophanes the Eleatic (born 620 B.C.) came forward with what was in form a new theory, yet in substance not widely different from that of his predecessors. According to Pythagoras, the Infinite Unity contains and produces everything. Xenophanes denied the possibility of such a production. If aught was made, he alleged it must have been either from that which was, or from that which was not: not the former, for if it already was, it could not be made; not the latter, for out of nothing nothing can come (*ex nihilo nihil fit*). Creation being therefore impossible, it necessarily follows that there is but *one* Being in the universe, eternal, absolute, infinite. Of this unconditioned being all finite existences, whether material or mental, are merely modifications. But had not his predecessors reached this unity of being before? Wherein, then, did Xenophanes differ from them in his doctrine of the One? In this, that, as Aristotle phrases it, "he cast his eyes wistfully upon the whole heaven, and pronounced that unity to be God." (*Metaph.* i. 5, § 7.) This Deity he endowed with self-existence and intelligence; but, denying him personality, he converted monotheism into pantheism.[2] Parmenides, Melissus, and Zeno, the other noted disciples of this school, while identifying thought and existence, and continuing the unitarian tendencies of the Eleatics generally, seem to have stopped short of an articulate avowal of pantheism. They all agreed, however, in the essential unity of being, and in the illusory character of sensible phenomena.

Heracleitus.

The next pantheist among the Greek ontologists was Heracleitus, "the weeping philosopher" (born 503 B.C.). The Eleatics founded their philosophy upon the certitude of the Reason; this thinker upon that of Sense. The former were rational pantheists; the latter was a material pantheist. For while Heracleitus held that we became conscious through the senses, he besides maintained that it was not we that became conscious, but the universal intelligence which became conscious in us. "Inhaling," he says, "through the breath the Universal Ether, which is Divine Reason, we become conscious."[3] With this philosopher, Fire was the first principle of things; it was ever kindling, ever dying out, and was identical with God. In this "perpetual flux and reflux" of things Hegel finds an anticipation of his doctrine, that "Being and non-Being is the same" (*Seyn und Nichtseyn ist dasselbe*). Hegel accordingly claims kindred with the melancholy old Greek, and alleges that he has developed every position of the Heracleitic system in his logic.

With Heracleitus the history of Greek pantheism properly closes. The only result of the unitarian systems of Elea, which were mainly pantheistic, was, as in the case of all erroneous forms of speculation, to shake the foundations of the human reason, and drive men to scepticism. This determination of human thought is actually to be found in the succeeding epoch among the Sophists. Socrates arose to put down the Sophists: Plato carried out the method of Socrates; and Aristotle brought this movement to a close. Philosophy in the hands of the Stagirite was once more reduced to a system; but it was not long till the sceptics of the succeeding epoch arose to demolish it. Doubt had its day; and no long time had elapsed when a new power arose in Christianity, taking hold upon the minds and hearts of men such as no system of belief had ever done before. This divine light broke forth in a region intermediate to the philosophical speculations of both the East and the West. Its influence was accordingly felt ere long both by sceptical Greek and mystical oriental; and out of this clash of opposing doctrines arose in the early centuries of the Christian era the sect called the Gnostics, and the philosophical movement known as the "Alexandrian schools." From both of these speculative movements arose evolutions of pantheism as thorough-going as any that had preceded them. Among the Gnostics, who attempted to harmonize orientalism and Christianity by torturing the latter to suit their eastern predilections, faith was subordinated to philosophy, rather than philosophy to faith. Their ontology was in general of a dualistic cast, but it not unfrequently took a turn towards pantheism. The most notorious of the latter class was Valentinus, who, so far as his precise doctrines can be ascertained, held all finite existences to be emanations from the "Universal" and "Unknown Father" (Βυθός), a sort of indeterminate Brahma, who was the sole being in the universe, and of which all else were but the modes.

Gnostics.

Neo-Platonic Pantheism.

On turning to the Alexandrian schools, we witness the collision of oriental ideas and Greek thought with Christianity. The first of the "Neo-Platonists" was Philo the Jew, born 27 B.C. at Alexandria. This eminent thinker had been long familiar with all the three modes of thought peculiar to the Platonist, the oriental, and the Jew. By distrusting the Senses, discarding the Reason, and taking refuge in Faith, he gave philosophy a determination towards mysticism, and united it once more to religion. (See MYSTICISM.) The material being thus gathered, it remained for Plotinus to give this speculative evolution a solid metaphysical basis. Farther attempts were made to perfect this eclectic system by his followers; but it continued to present a strange agglomeration of doctrines, all swallowed up by the all-embracing one of pantheism.

Plotinus.

The object of philosophy, these thinkers held with Plato,

[1] A novel and ingenious, if a somewhat arbitrary, explanation of the Pythagorean doctrine of Number, is given by Professor Ferrier in his *Institutes of Metaphysic* (prop i., § 16, p 88). He holds that Pythagoras made Number the ground of all conceivability. "In nature, *per se*," he says, "there is nothing but absolute inconceivability. If she can place before us things, she cannot place before us *a* or *one* thing. So said Pythagoras. According to him, it is intelligence alone which contributes *a* to a 'thing,' gives unity," &c. This exposition of the doctrine has at least the merit of being intelligible. Aristotle, however, who was not deficient, we presume, either in acuteness or in general information respecting such matters, seems to have held a different view from the Professor. (See *Metaph.*, i. 5.)

Pantheism.

Plotinus.

to be Universals, of which all phenomena were but the modes. This ideal world, again, of Universals was but the mode of God's existence. But how can I, a finite being, comprehend God, who is infinite? It is obviously impossible so long as I remain finite. Since, then, I *do* possess a knowledge of the Infinite, it cannot be through my reason, which can only deal with finite things, but through some *higher* faculty, altogether impersonal, by which I become for the time being infinite, and am identified with the object of my contemplation. "The faculty," says Plotinus, "by which the mind divests itself of its personality is *Ecstasy*. In this ecstasy the soul becomes loosened from its material prison, separated from individual consciousness, and becomes absorbed in the Infinite Intelligence from which it emanated. In this Ecstasy it contemplates real existence; it identifies itself with that which it contemplates."[1] Here, then, is the doctrine of Absolute Identity in all its fullness, of which pantheism is but the corollary. Thought and thing are identical, and this is the only possible ground of knowledge. We know the Infinite, according to Plotinus, by an immediate intuition (παρουσία), out of and beyond reason; we know it, according to Schelling, through an "intellectual intuition." Thus the fundamental position of both systems is the same.[2] By a process of subtle dialectics the Alexandrians came to the conclusion that the Deity consisted of a Trinity in Unity. This Trinity consisted of the *hypostases*, of which the first is *Unity* simply, not properly Being; the second, *Intelligence*, which is identical with Being, Mind, absolute and eternal (νους): third, the *Universal Soul*, the Soul of the world (ψυχή τοῦ πάντος or τῶν ὅλων), the source of all activity and life, mental and material. In his highest state, Deity is neither thought nor existence, but simple *Unity*, reminding one of Hegel's Absolute Nothing. The next peculiarity of this system—the corollary indeed of what has gone before—is the law of Emanation, or the mode in which the world of mind and matter is produced by the Universal Soul. It is at this point the pantheism of the "Neo-Platonists" becomes palpable. If God made the universe, he did so, says the human reason, so far as it can give a deliverance on the matter, either from his own substance or from something else already existent. If the former, Deity and the universe are in fact identical,—hence pantheism; if the latter, Deity and the universe are radically and eternally distinct, which is the assertion of dualism, but no satisfactory explanation of the origin of the world. The Christians affirmed that God made the world out of nothing by the energy of his own omnipotence; the Alexandrians maintained that he made it out of his own substance, but that, while not distinct from him in *essence*, it was nevertheless distinct from him in *act*. The pantheism thus reached is of the most refined and subtle character. Instead of confounding God with the world, after the manner of the material pantheists, the Alexandrians held that the nature of Deity was not exhausted in the act of creation, although the matter created was identical in essence with himself. Thus, while the ordinary pantheistic formula, "All things are God," holds true for this system, its converse, "God is all things," is directly opposed to its express development of the law of Emanation. Proclus, with whom ancient philosophy properly ends, terminated the speculative evolution of the "Neo-Platonists." He endeavoured to work up into methodical connection the labours of his predecessors in that school; and brought as subtle a scientific faculty to the task as any that had yet been known among the Alexandrians. (See especially his *Institutio Theologica*.)

Pantheism.

Middle Age Pantheism.

Scotus Erigena.

On descending to the philosophy of the middle age, we come in contact with a man of great learning and original genius in the person of John Scotus Erigena, who flourished during the seventh century. This eminent thinker stands alone as an original advocate of pantheism during that entire epoch. So far as Erigena was indebted to previous speculators, Neo-Platonism, combined with eastern thought, seems to indicate the direction of his philosophy. The traditionary account of his travels in the East seems to be confirmed by the striking and almost literal coincidences which Colebrooke detected between parts of his writings and certain portions of the Sankhya philosophy. He begins with Absolute Unity as the origin and essence of all things, and endeavours, in his *De Divisione Naturæ*, to explain how this radical unity, or Deity, has produced the universe of multiplicities with which he is emphatically identical. From the plenitude of the Divine Intelligence first causes (*primordiales causæ*) are derived, which give birth in turn to the world of nature, destined ultimately to return to the bosom of the Absolute. Like Proclus among the Alexandrians, and like Hegel in more modern days, Scotus Erigena seems to have maintained the strict analogy and correspondence of the world of ideas and the world of realities; so that the relations of human thought are properly expressions of the real relations of the universe.[3] "If," he says, "the knowledge of all things is the reality of all things, this cause [viz., Deity] which knows all is all." He again winds up his theory of human knowledge in these words:—"Everything is God; God is everything; God is the only real substantial existence." The pantheism of Erigena again reappears towards the end of the twelfth century, in the speculations of Amaury de Chartres, and, with modifications, in those of his pupil David de Dinant, who was a material pantheist.

Modern Pantheism.

Bruno.

The brilliant and unfortunate Giordano Bruno, who was burnt as a heretic in the streets of Rome in 1600, stands prominently forward in the records of philosophy as the precursor of Benedict Spinoza. Bruno's pantheistic system, which is little more than a purification and development of the speculations of the Eleatics and of Plotinus, is set forth with singular eloquence and richness of poetic colouring. With him, Deity, the Infinite Intelligence, is the principle and essence of all things (*natura naturans*): he is the cause of the universe (*natura naturata*), yet he did not create it; he simply informed it with life, for he is the universe, although not limited by it. He is self-existent, absolute, and simple. He is incessantly active as a cause; and all his energies are determined by his nature. His activity is necessary; and yet he is perfectly free. The universe is the infinite activity of his mind; and hence it is infinite, eternal, and imperishable. To hold the contrary were to limit his power. But while Deity is thus the essential substance of the universe, he is nevertheless separated from nature: he is *superessentialis*, just as a mind is conceivable apart from any one of its thoughts. The universe is properly a living being, an immense infinite animal; and Deity, as the soul of the universe, modifies and influences it throughout all its parts. There exists but one sole intelligence which dwells in God in perfection, but in inferior spirits in imperfection, varying according to the capacity of their natures down to the lowest level of created beings. These differences of endowment are not generic, however; they are simply differences of degree. Man occupies a middle place in the scale of intelligence; and his noblest function, according to Giordano, is to discover the harmony that exists between the order of the

Pantheism. external universe and the internal ideas of the soul; to perceive the identity of his intelligence and that of the Deity, of the Subject and Object of thought.[1] There is no real distinction between good and evil, between happiness and misery, between beauty and deformity; all are essentially good, proceeding as they do from good, and intended as they are for the best. Such distinctions are therefore merely relative and illusory; they are not absolute and real.

Spinoza. In 1632, just thirty-two years after the burning of Bruno, was born in Amsterdam, Benedict Spinoza, who was destined to give a method and shape to the heretical theory for which the Italian suffered, such as it had never received before at the hands of man. No speculator is more frequently abused than the subtle Jew, and no one is less understood. The legitimate and even avowed consequences of his system induce the belief—perhaps a natural one—in thoughtless minds, that the author of them must have been a very bad man. Yet such was not the case. He lived a thoughtful, industrious, and strictly moral life, grinding optical glasses for his livelihood, and spending the remainder of his time in calm, speculative seclusion. He seems to have been a man of a naturally reverential and earnest disposition. This appears frequently from certain attitudes of mind and turns of thought in his writings, as well as from the fact that, in his great work, the *Ethica*, in which his pantheistic system is elaborated, it was his design to deduce mathematically from the knowledge of God the fundamental laws of morality, and the principles that should regulate human life.

Philosophical critics have got up a polemic as to whether or not Spinozism was a legitimate development of Cartesianism; whether or not the philosophy of Descartes contained in embryo that of Spinoza, and only required the speculative courage and strong logic of the Jew to convert it into pantheism.[2] Considered in itself, and especially in relation to the philosophers in question, the dispute,—as indeed all such usually are,—is rather an idle one than otherwise. Suffice it to say, that Spinoza studied the works of Descartes with intense interest and admiration, as is abundantly evinced by his unrivalled abridgment of the doctrines of that philosopher, and, in particular, that he agreed with the Cartesians in holding that what was true in thought was true also in things. The latter principle formed the basis of Descartes' main argument for the existence of Deity; and Spinoza resolved, if possible, to put it to a more extensive and solid use. He accordingly set to work to develop by strict mathematical demonstration an ontological system embracing Deity and the universe. His scheme is developed in the work, published posthumously in 1677, entitled *Ethica, Ordine Geometrico Demonstrata; et in quinque partes distincta; in quibus agitur*—I. *De Deo;* II. *De Natura et Origine Mentis;* III. *De Origine et Natura Affectuum;* IV. *De Servitute Humana seu de Affectuum Viribus;* V. *De Potentia Intellectus seu de Libertate Humana.* Such is the plan and range of this celebrated work. First God, then man, the laws of his nature, and the character of his activity. With Spinoza, as with all pantheists, the main point to be attended to, in order to a comprehension of his system, is the method which he employs. The only "refutation of Spinoza" (and how many such have there been!) consists in rejecting his method as false and illegitimate. Other pantheists may be overthrown by their pursuing the suicidal course of inconclusiveness. But it is not so with Spinoza; for no single opponent, nor any combination of hostile criticism, has yet succeeded in convicting this arch-pantheist of tripping in his logic, or of wandering far from the method with which he set out. Once grant the all-sufficiency of logic, the essential harmony of thought and existence, and the infallibility of the *deductive* method, and the chances are, that in the hands of an able and daring thinker the ontology of the universe will be pantheistic. So at least was it with Spinoza. His method deceived him; and in proving true to it, he became a pantheist. Spinoza opens the first book of the *Ethica*, which is entitled *De Deo*, in genuine geometrical fashion, by laying down a series of definitions and axioms, from which he proceeds to evolve demonstratively, in a set of theorems each dependent on what has gone before, his entire scheme of God and the world. This he does with uncommon accuracy and clearness of language; so that if it is difficult to understand him, the defect does not lie in the author. Before entering upon a brief analysis of his system, it is necessary to exhibit his definitions and axioms.

Pantheism. Spinoza.

DEFINITIONS.[3]

1. By a thing which is its *own cause* (*causa sui*) I understand a thing of which the essence involves existence, or a thing which cannot be conceived of except as existent.

2. A thing is said to be *finite, in suo genere*, which can be limited by another thing of the same nature; *e.g.*, body is called finite because we can always conceive another body as larger. So one thought is limited by another thought. But body is not limited by thought, nor thought by body.

3. By *substance* I mean that which exists in itself *(in se)*, and is conceived by itself *(per se)*; the conception of which, in other words, does not involve the conception of anything else as the cause of it *(a quo formari debeat)*.

4. By *attribute* I understand that which the intellect perceives as constituting the very essence of substance.

5. By *mode* I mean an affection (*affectio*) of substance, or that which is in something else, through which also it is conceived.

6. By *God* I understand a being absolutely infinite, that is, a substance consisting of infinite attributes, each of which expresses an eternal and infinite essence.

Explanation.—I say absolutely infinite, but not infinite *suo genere;* for whatever is infinite *suo genere* only, does not possess infinite attributes, whereas that which is absolutely infinite contains in its essence whatever implies essence, and involves no negation.

7. A thing is said to be *free* which exists by the sole necessity of its own nature, and by itself alone is determined to action; but that thing is *necessary* (*necessaria*), or rather constrained (*coacta*), which owes its existence to something else, and is determined to action according to a fixed and definite method.

8. By *eternity* I mean existence itself, in so far as it is conceived to follow necessarily from the sole definition of an eternal thing.

Explanation.—For this kind of existence is conceived as an eternal verity, and cannot therefore be explained by duration or time, even though this duration should be conceived as without beginning and without end.

AXIOMS.

1. All things which exist, exist either of themselves or through something else.

2. That which cannot be conceived [as existing] through something else (*per aliud*) must be conceived [as existing] through itself (*per se*).

3. From a given determinate cause an effect necessarily follows; and if there be no given determinate cause, no effect can follow.

4. The knowledge (*cognitio*) of an effect depends upon and implies the knowledge of its cause.

5. Things that have nothing in common with each other cannot be understood through each other; in other words, the conception of the one does not involve the conception of the other.

6. A true idea (*idea vera*) must correspond with its object (*suo ideato*).

Pantheism. Spinoza.

7. Whatever can be conceived as non-existent, the essence of that thing does not involve existence. (*Ethica*, pars. i., pp. 187–8.)

Such is the foundation on which Spinoza commences to rear the vast edifice of his ontology. It will be perceived that, alike in definition and in axiom, he adheres strictly to the method which he has resolved to pursue, and which has been already alluded to. This he continues to do throughout proposition, corollary, and scholium with an accuracy and rigour which Euclid himself has not surpassed. Without taking up in detail the successive evolutions of his system, a rapid outline of it may here be given.

There are two classes of existences, according to Spinoza, which appear to be real, but whose reality lies merely in appearance. These are the phenomena of Mind and Matter, on the one hand, and what are called the substances Mind and Matter, on the other. Existence is but accidental and transient in these objects; and hence there must be somewhere a being or beings endowed with the characteristic of self-existence: there must be a substance underlying all these accidents and changes, and that substance must be self-existent. This follows from the very definition of substance, the essence of which implies existence as part of the idea. It is obvious there can be but one substance possessed of self-existence, and that one substance is God. But to see how this position is established, and also to witness a specimen of Spinoza's logic, we may turn to

Proposition XIV.—*There is no substance but God, nor can any other be conceived.*

Demonstration.—Since God is a Being absolutely infinite, possessed of every attribute (by defin. 6) which expresses the essence of substance, he necessarily exists (by prop. xi.). If there is any other substance besides God, it must be explained by some attribute of God; and thus two substances would exist possessed of the same attribute, which (by prop. v.) is absurd. There is therefore no substance but God, and hence no other can be conceived. For, if such could be conceived, it must be conceived as existent, which, by the first part of this demonstration, is absurd. Wherefore, there is no substance but God, nor can any other be conceived. Q.E.D.

Corollary 1. Hence, it very clearly follows, in the first place, that God is one; *i.e.* (by defin. 6), there is only one substance in nature, and that substance is absolutely infinite, as already hinted in the scholium to prop. x.

Corollary 2. It follows, in the second place, that an extended object and a thinking object are either attributes of God, or (by ax. 1) affections of those attributes. (*Ethica*, part i., p. 197.)

There is, accordingly, but one substance, infinite, self-existent, eternal, necessary, simple, and indivisible, of which all else are but the modes. God, as the infinite substance, with its infinity of attributes, is the *natura naturans*. As the infinity of modes under which his attributes are manifested, he is the *natura naturata*. God is the immanent, but not the transient, cause of all things. The universe is not God, but simply the necessary modes of being of his attributes. According to Descartes, there were two substances, Spirit and Matter, of which the essences were respectively Thought and Extension. But as Thought and Extension are only modes of existence, and as there can be only one substance, it follows, according to Spinoza, that Thought and Extension are two infinite attributes, and the only two known to us of the one infinite substance.[1] Now, as the attributes of Deity are only different manifestations of one nature, infinitely absolute, it follows that there must be a complete harmony and correspondence between the successive modes of one attribute and the successive modes of every other. Thus, a mode of thought[2] must correspond with a mode of extension; every idea must harmonize with its ideate or object, being only the same phenomenon under a different aspect. Extension is Thought objectified, and Thought is Extension subjectified. What God does as an extended substance, he thinks as an intelligent substance; for thought and thing, subject and object, are in him absolutely identical. All things are modes of his attributes of Extension, and all thoughts are modes of his attribute of Thought. The circle is a mode of God under his attribute of Extension: the idea of a circle is the corresponding mode under his attribute of Thought.[3]

Again, as Deity is necessarily existent, he can only act through and by the necessary laws of his being. Freedom, in the ordinary sense of that term, is accordingly incompatible with the only legitimate idea of such a being; but freedom, in the proper sense of the word, as applicable to a being whose acts are determined solely by the laws of his essential nature, can not only be predicated of Deity, but can be predicated of him and of him alone of all beings in the universe. And as good men are free when most a law to themselves, so we magnify God's freedom when we affirm he *must* have acted as he has done. His acts are therefore at once free and necessary: necessary, from the very essence of his nature; and free, from the very nature of their necessity. The nature of man being limited, and his existence derived, he cannot act as a free cause, in the proper sense of that term. What we ordinarily call "will" (*voluntas*) is simply a mode of thought, is simply a link in the causal nexus which binds all phenomena to the one *causa causarum*. "Will" cannot therefore be applied to Deity (*voluntas non potest vocari causa libera, sed tantum necessaria*, prop. xxxii.), nor does he possess any proper personality. It follows, again, that in God there can be no such distinction as good and evil, and in ascribing moral qualities either to his actions or to those of ourselves, we simply indulge in baseless fancies (*entia imaginationis*) which have no real existence, and which are derogatory to the true dignity of God. For our convenience, we form these abstractions of human excellence; but in the eye of God, everything is just what it has the means of being; and there is properly no resistance of his will.[4]

But to pass to a more special consideration of man. Man is composed of *Body* and *Spirit*. But Body and Spirit, as has been already shown, are not two independent realities. Body is but a mode of Extension, and Spirit is but a

[1] That Spinoza makes this infinite substance *material*, as some have alleged, is entirely erroneous; for body with him is but a mode of Extension, while Extension itself is an attribute of the one Substance—Deity. There is therefore equal warrant for making the Deity of Spinoza *spiritual* as there is for making him *material*; for in point of fact He is properly neither, being the identity, as Spinoza expressly states, of the *natura naturans* and the *natura naturata*. Materialism and spiritualism are equally indifferent to Spinoza, and he accepts of the extremes of both systems with like equanimity.

[2] It is scarcely necessary to observe that "Thought" (*cogitatio*) is used by Spinoza in the Cartesian sense, as equivalent to any mental mode, whether cognition, feeling, or volition.

[3] It will be perceived that the celebrated "pre-established Harmony" of Leibnitz is little more than an adaptation of the singularly ingenious theory of the great pantheist. With Leibnitz, mind and body are adapted to each other by a pre-ordinating power; with Spinoza their movements coincide, because they are *essentially the same*,—idea and ideate being the same modification of the one absolute being, but manifested through different attributes. (For further illustration on this point, see an able article on Spinoza in the *Westminster Review* for July 1, 1855, attributed to Mr Froude.)

[4] Such is the extraordinary manner in which Spinoza explains the mystery of evil. It might be supposed at first sight that his system makes God the real cause of all the error and crime that is in the world; but such a conclusion he avoids by leading a proof of the positive non-existence of what is called evil. When Blyenbergh presses him with this difficulty, Spinoza replies calmly, as is his wont, "God is really and absolutely the cause of all things which have real existence (*essentia*), whatever they may be. If you can demonstrate that evil, error, crime, &c., have any real existence, I entirely admit that God is the cause of those evils, errors, crimes, &c. It appears to me, however, that I have sufficiently shown that what constitutes the real essence of evil, error, crime, is no real thing at all, and therefore that God cannot be regarded as the cause of it." (*Epistola* xxxvi., § 4, vol. ii., p. 255.)

Pantheism. Spinoza.

mode of Thought. Thought and Extension are attributes of the one absolute substance, God, evolving themselves in two parallel streams, so to speak, of which each separate body and spirit are but the waves. What I call my mind is only a succession of certain modes of Thought: what I call my body is only a succession of certain modes of Extension. The sum of my ideas, at any moment, constitute my soul: the sum of my material qualities, at any moment, constitute my body. Body and soul are apparently two, but really one: they have no independent existence: they are parts of God. The human mind is percipient of bodily affections, —not directly, but by coincidence; and as it belongs to the nature of thought to cognise its own modifications, as well as those of the other attributes of Deity, the human mind, being a portion of that thought, is likewise cognisant of the ideas of corporeal affection. In other words, the mind is self-conscious; or, as Spinoza expresses it, "Mens se ipsam non cognoscit, nisi quatenus corporis affectionum ideas percipit." (*Eth.*, pars. ii., prop. xxiii.) Perception is of two kinds—adequate and clear, inadequate and obscure. An idea is adequate and clear when it conforms to its object; inadequate and obscure when it imperfectly represents it. The former class is positively true, the latter negatively false. Inadequate and false ideas are either the ideas of bodily affections or the perception of those ideas. Adequate and clear ideas are those abstracted from the former class, and elaborated by a process of reflection. This reflective process is regarded as being within the direction and control of the mind itself; and here, in his theory of knowledge, as well as afterwards in his theory of morals, Spinoza, in the judgment of some, departs from the absolute necessitarianism which his system induces, and which he himself had already avowed.[1] It may be noted, however, that Spinoza was perfectly well aware that the theoretical aspect of man's relation to the all-embracing nexus of causation seldom influences very materially the ordinary practical bearings of any question involving self-control; nor did he forget, at the same time, that a certain measure of self-direction may be not inconsistent with a scheme of the most thorough-going necessitarianism. But it is not to be forgotten that such considerations, as resulting from psychological observation, and not from the application of the method of formal demonstration which Spinoza professes throughout to employ, cannot be regarded as falling in harmoniously with the other evolutions of his system. Nor do they; for at bottom, and on such a scheme, personality is only phenomenal, and human liberty an illusion. The better we know, according to him, the better we act; and upon this hypothesis he passes on from the sphere of knowledge proper, to a consideration of the passions and affections of human nature. There is a necessary desire in all being, says Spinoza, to remain in existence. God, whose essence is existence, is possessed of this desire; but as his being is under no limitation, he is absolutely perfect and perfectly happy. But the human soul, while participating in this desire of Deity, is necessarily limited, and hence necessarily unhappy. This desire for a continuance of being becomes in man a desire to remain intelligent, and, if possible, since limited, to enlarge the sphere of his knowledge, seeing that knowledge is the constituent element of the mind. But this simple and fundamental activity of our nature is frequently impeded in its development by the obstruction of external causes consequent upon our inadequate and confused knowledge. Hence emerges from the bosom of this primary desire a new class of emotions termed *passions*, such as joy and sorrow, hope and fear, love and hatred, &c. To increase the sum of our being is accordingly the great end of life: the pursuit of this end is virtue, and the attainment of it happiness. To perfect happiness, therefore, it is necessary to diminish the number of our inadequate ideas; for it is owing to these that passion and pain have any existence. Phenomenal knowledge of sense and internal perception, such as occupies the attention of the great mass of mankind, is the fertile source of the ills to which they are exposed. Now, to escape from these evils incidental to obscure knowledge, it is necessary to get behind phenomena, and to inquire into the relations, causes, and essences of things, until we have grasped the attributes of God. This is the first stage of clear and adequate knowledge; but it is not the only one. To sages and men of devout meditation a third and highest degree of adequate knowledge is attainable in rising to the universal and absolute idea of God. As here is the highest light, so here is the most perfect peace. Were our knowledge of God capable of present completeness, we might attain to perfect happiness; but such is not possible. Out of the infinity of his attributes, two only—Thought and Extension—are accessible to us; while the modes of those attributes being essentially infinite, escape our grasp. Universal science is thus possible for God alone, and he is the only being absolutely happy. We may nevertheless, by prosecuting arduously and courageously our real good, enlarge the boundaries of positive knowledge, and thus emancipate ourselves from the tyranny of ignorance and the slavery of passion. To know God and to love him is thus the true source of self-mastery, peace, and blessedness.

It follows from the unequal distribution of clear and adequate knowledge, that men possess real being in very unequal degrees. And it is from this fact that Spinoza deduced his ingenious and startling theory of the immortality of the soul. Such a doctrine is at first sight impossible in Spinoza's philosophy; for, as the soul is only the collection of our ideas, and as our ideas have their origin in the affections of body, it necessarily follows that the destruction of the body at death is the destruction of our ideas, and the consequent annihilation of the soul. But Spinoza, while granting the validity of this conclusion, qualifies it in a very important manner. He reminds us that all knowledge is not necessarily phenomenal; that there are adequate as well as inadequate ideas; and that while the latter perish with the body, whence they arose, the former are absolutely indestructible. For, as occupied with the essences of things, with the attributes of God, or with God himself, the human soul, even although the body were destroyed, would find objects of thought, time without end, in what is essentially permanent and enduring. For men who are destitute of this higher knowledge and being there is on this system no positive hereafter. And this Spinoza calmly admits. The man who has been the slave of passion; who has had no love or knowledge of God as the source of all goodness; who has possessed no proper personality while living; who has, in short, been wholly occupied with the body, will lose everything in losing the body. Our immortality, then, rests with ourselves. It is the reward of a life of virtue and of high noble endeavour.

Such, then, are the main features of a pantheistic system of philosophy which has never been surpassed in bold ingenuity, and never equalled in scientific rigour. However we may be disposed to regard the moral consequences of its general reception, it must not be denied that, in the hands of the author, it was by no means an immoral system. To try Spinoza by a Christian standard may be instructive, but it is hardly just, for he never was, nor professed to be, a Christian.[2] Monstrous as his philosophy is when viewed in

[1] Even so acute a thinker and fair a critic as Theodore Jouffroy, on reviewing this development of Spinozism, affirms, "Here is the radical contradiction lurking through his whole system." (*Introduction to Ethics*, 2d Lecture on "Spinoza.")

[2] Yet the school of Herder and Schleiermacher in Germany have claimed him as such.

Pantheism.

many of its ramifications, and pernicious as must be the result of its practical adoption, it is beyond a doubt that the author does not seem to have so regarded it. The system is profoundly false, and the heart of man rises up in wrath against it; yet it is not fair, as is often done, to denounce Spinoza as an atheist, or to regard him as essentially a bad man. Novalis called him a god-intoxicated man (*Gott trunkner Mann*), an epithet which, if we may judge from the frequency of its quotation, seems to have been regarded by many as a happy one. Pantheism and atheism are not in strictness identical; yet it is true they are not far separated in their practical tendencies. It is no new remark, however, that men are frequently better than their doctrines; and (so inconsequent and self-deceiving is man) while soundness of doctrine is no absolute guarantee for purity of life, so erroneous opinion is not necessarily accompanied by habits of vice. Exceptional cases, however, should not be made the bases of laws, any more than imperfect moral inductions should be elevated into absolute standards of moral life.

Schelling and Hegel.

In following the progress of pantheistic speculation, as traceable in the annals of philosophy, the ontological systems of modern Germany should next demand attention. As, however, the speculative systems of Schelling and Hegel—the most celebrated pantheists of modern times—have been treated of in the article METAPHYSICS, under the section devoted to "Ontology," no special notice of these philosophers is required here; and the reader is referred once for all to that article for further information respecting the most recent evolutions of pantheism.

Estimate of Pantheism.

Such, in conclusion, is an outline of the numerous attempts at constructing a science of Being which have ended in pantheism, which is but another name for failure. And in this we have an epitome of the history of all such attempts. Did the results of pantheistic speculation, as of many other fantastic follies of the human brain, terminate merely when the ingenious fabricator had placed the last cope-stone upon his imposing edifice, they might excite a smile, as the harmless amusements of misdirected genius, but would awaken no serious alarm in the breasts of earnest men who are interested in the advancement of truth and the triumph of goodness. But such speculations have a more intimate practical bearing, both directly and indirectly, than might at first sight be supposed. For, apart from the opprobrium which they bring upon philosophy for its speculative variation and egregious absurdity, such doctrines exert a more subtle and dangerous influence in determining men to scepticism, and to a disregard of the ordinary obligations of morality and religion. For if philosophers, by sheer dint of a reckless logic, wring conclusions from the human reason abhorrent to the common sense and shocking to the conscience,—thus bringing into hostile collision the primary elements of our nature,—what escape is there from the most complete intellectual doubt, from the most absolute moral indifference? Thoughtless men may smile or sneer at all such speculations as equally foolish and harmless; but there is assuredly a Nemesis in all erroneous speculation, as there is in all wrong-doing. And this retribution comes not unfrequently nearer the ordinary business and bosoms of men than they are well aware of. A word, then, on the *method* pursued by the pantheistic philosophers, for it is here the vice of their system lies.

The total falsehood of all pantheistic systems may be established both directly and indirectly:—directly,—1. From its misapplication of the laws of thought; and, 2. From its violating, *in limine*, the original data of consciousness: indirectly,—3. From its virtually contradicting the intellectual and moral consciousness of mankind; and, 4. From its rendering religion impossible.

Pantheism.

1. The one invariable method employed by pantheists is the formally deductive. Now, this method, in order to be thorough-going, in order to transport the thinker into the sphere of absolute existence, would, first of all, require to vindicate the possibility of such existence; would next need to establish the fact of its existence in general; and would, lastly, be constrained to demonstrate its special existence as determinate and individual reality. Now, are all, or is any, of these tasks possible for the logical method of sciencing Being? The laws of formal thinking are those of Identity, Contradiction, and Excluded Middle.[1] These laws, as admitted on all hands to be merely regulative and analytical, cannot, of course, *add* to what already is,—cannot, in point of fact, furnish any existent reality at all. They can neither say *that* a thing is, nor *what* a thing is; they can merely say what it is not. Being merely explicative, and perpetually employed on the evolution of identical propositions, they are limited in strictness to the sphere of what is already fixed upon as determinately existent, and as clearly defined. A single *fact* the laws of logic cannot afford; and when once a fact is postulated, they can never in any degree amplify its positive contents.[2] Before it is possible to apply the laws of formal thinking in the pursuit of determinate existence, we would require to define existence in general. But do we know anything of existence in general? Is existence *per se* aught more than a mere abstraction? And if only a mere abstraction, no application to it of the laws of formal thinking can ever succeed, as has just been shown, in clearing the boundaries of abstraction and gaining the territories of real existence. In short, all such demonstrations begin with abstractions and end with abstractions. This brings us to consider—

2. Wherein does the pantheist violate the original data of consciousness? In this, eminently, that he ignores the essential condition of knowledge in arrogating to himself a capacity for defining existence *per se*, which involves a violation of the limitation of all human knowledge. Spinoza demonstrates that Substance exists because the essence of it implies existence as part of the idea, according to his definition of Substance. Here he makes two erroneous assumptions. In the first place, he identifies thought and existence in assuming that his *idea* of Substance and the *thing* Substance are convertible; and, in the second place, he assumes that we have a knowledge of absolute Substance, of Substance irrespective of all qualities, which contradicts the articulate and unequivocal deliverance of consciousness respecting the essential relativity of all our knowledge. In short, Spinoza, and all metaphysicians with him who employ the deductive method of philosophizing, virtually maintain with the sophist Protagoras, that "man is the measure of the universe, both of that which is, and of that which is not." Everything is and must be as we conceive it; an assumption which is not only destitute of a shadow of foundation, but is directly opposed to positive evidence to the contrary.

3. But not only may pantheism be redargued in its premises,—it can also be proved false from the consequences to which it consistently leads. These consequences are both intellectual and moral: intellectual, in contradicting the primary deliverances of consciousness, which assert the real antithetic existence of Self and not-Self; and moral, in giving the lie to the conscience, and denying the possibility of moral obligation. The pantheist maintains that, as man's personality is merely phenomenal, and his power of self-control at bottom but a chimera, every one's actions, whether external or internal, are determined by causes over which

[1] For further information respecting those laws, see LOGIC; also Appendix I to Sir W. Hamilton's *Discussions on Philosophy*, &c.

[2] The reader will find this admirably put by Mr John Veitch in Appendix C, iii., to his *Memoir of Dugald Stewart.*

he has no influence, and which utterly deprive him of any power of moral choice, or of any control over his conduct. His actions, as properly those of Deity, are all equally divine. Responsibility is thus but an illusion,—an *ens imaginationis*, as Spinoza would say,—and moral obligation naught but a plausible fiction. Conscience may be, perhaps, of a little practical use; for, as Spinoza allows, we are obliged occasionally to regard the future as contingent; but, however convenient such a supposition may be, it is wholly destitute of foundation, and contrary to the truth. Fortunately for humanity, their moral judgments are not to be silenced by such reasoning; and morality or truth has nothing ultimately to fear from any conclusions which rest upon false premises, or do violence at the outset to the universal consciousness of mankind.

4. But not only is pantheistic speculation, when carried into practice, destructive of moral activity, it likewise cuts off the possibility of religion and of religious worship. For, in the first place, the God of the pantheist is not the Deity before whom human nature feels constrained to bow. The One abstraction which gathers up into its alleged sole reality all the other existences of the universe—the identity of the *natura naturans*, and the *natura naturata*—is not that God in whose presence the human heart is filled with humble reverence and holy adoration. In the second place, if all things, and myself among the rest, are properly God, what room is there for worship? How can God be said to worship himself? In short, there is hardly any conceivable limit to the wild extravagances and pernicious consequences which legitimately spring from a consistent adherence to pantheistic doctrines.

Beside the bane, however, grows up the antidote. If we will only rest content with the small portion of truth which is legitimately within our reach, and eschew the ambitious and blind folly of aspiring to the sum of knowledge, we may still experience the happiness of conscious, if humble, security, while safe from the fatal delusions of those who unduly lust after intellectual power. Philosophy is not to be despaired of although a philosophy of the Absolute is impossible; and truth has not necessarily come to an end because man is not "the measure of the universe."[1] Pantheism, like all error, is unquestionably doomed; and as soon as the world can afford to do without it, we shall doubtless cease to hear any more of it. Meanwhile, it is the duty of the earnest speculator to adhere to what is legitimately placed within his reach. Observation and experiment, the judicious use of a rational induction, is the only method vouchsafed to man whereby truth is to be attained—if attainable at all—in such high matters. This method may appear vulgar and pedestrian to the proud eye of ambition; it may prove comparatively barren—nay occasionally unsatisfactory—in its results; but no method of inquiry can ever become contemptible which alone conducts man to the possession of truth. Philosophies without number have been tried and found wanting; but there remains still for the wise thinker as much truth as is necessary for the conduct of human life, if not sufficient to disclose to mortal gaze the hidden mysteries of the universe. (J. D—S.)

PANTHEON. See ARCHITECTURE.

PANTICAPÆUM. See KERTCH.

PANTOGRAPH, an instrument contrived for reducing, enlarging, or copying plans. It has been constructed in

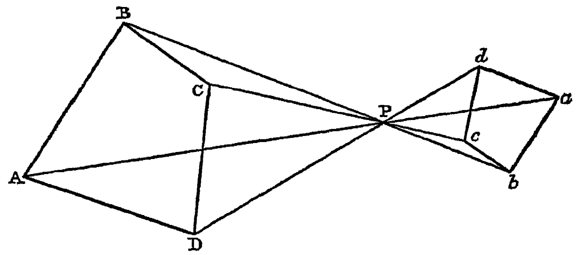

Fig. 1.

a variety of forms, all of them depending on the same geometrical proposition. If from the corners A, B, C, D (fig. 1) of any polygon, lines be drawn to a fixed point P, and be continued to distances Pa, Pb, Pc, Pd, proportional to PA, PB, PC, PD, the figure *abcd* is similiar to ABCD.

In order to utilize this property, a bar EPe (fig. 2) is made to turn freely upon the point P; on E and e are jointed two

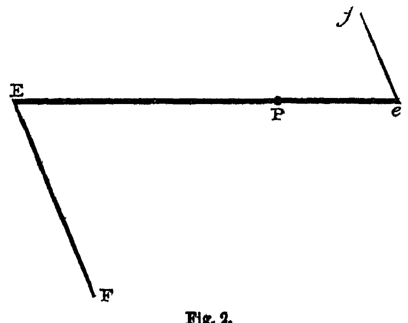

Fig. 2.

other bars EF, *ef*, having their lengths in the ratio PE to Pe, and being kept constantly parallel to each other by some mechanical contrivance. In this way the points F, P, and f are maintained in a straight line, and the ratio of FP to fP is preserved constant; so that if the point F be led along the contour of any figure, f must mark out a similar figure.

In the old form of the pantograph the parallelism of the bars EF, *ef* was secured by a thin rhomboidal frame like the common parallel ruler, the several joints being supported on small ivory castors. Hence the whole apparatus moved by jerks, and it was impossible to follow with precision any delicate outline. In the eidograph of Professor Wallace, the parallelism is maintained by means of two light wheels, round which a chain is passed, and the machine is supported by long axes; while in Dunn's pantograph, the rhomboidal frame is used with long axles. With these improved forms a free and smooth motion is obtained, so that very minute work can be gone over.

At one of the points F, f there is placed a tracing-style of steel, delicately pointed, but not sharp, to be led along the outline of the plan, and at the other a tracing-pencil, kept pressing on the copy-paper by a small weight which can be pulled up when required. There are also arrangements for altering the lengths of the arms to suit the ratio in which the plan is to be diminished or enlarged.

The pantograph is extensively used in the arts; thus, the machine-embroiderer leads the longer arm over a magnified copy of the figure to be produced, and guides with ease and precision the successive strokes of the needles. To this simple contrivance we owe much of the beauty and cheapness of flowered muslins and embroidered silks. (E. S.)

PANTOMIME (πᾶν, *all*, μῖμος, *an imitator*), is one who imitates all sorts of actions and characters by means of gesticulation alone. This species of actor was common to the civilized nations of antiquity, and especially to Greece. The pantomimes proper, however, who resembled very nearly the modern ballet-dancers, were peculiar to Rome, where the art was carried to great perfection during the reign of Augustus. This art was discountenanced by Ti-

---

[1] Lewes, true to the spirit of his philosophical creed, confidently asserts that one can only escape Spinozism "by denying the possibility of all philosophy."—(See *Biog. Hist. of Phil.* "On Spinoza's Doctrine.")

berius, but it revived again under Caligula and particularly Nero. Lewd, mythological love stories were the favourite subjects chosen for pantomimic-acting; and the pernicious effect of such spectacles is vehemently satirized by Juvenal (vi. 63, &c.) These representations were founded on a text mostly written in Greek: the movements of the actors were rhythmical; and hence the entire art got the name of *musica muta*. In Sicily such dances were called Βαλλισμοί, whence some have derived the words *ball* and *ballet*.

In the modern drama, the term *pantomime* is applied to a mimic representation by gestures, actions, and amusing tricks, performed by certain fantastic characters known as Harlequin and Columbine, Pantaloon and his Clown, &c. The *pantomime* is sometimes also a sort of dramatic entertainment appended to the Italian opera.

PANUCO, a town of Mexico, in the state of Vera Cruz, on the banks of a river of the same name, 18 miles W. of Tampico. The situation is extremely beautiful; and in the neighbourhood of the town there are many remains of antiquity, extending over a rich tract of ground. Pop. about 4000.

PANVINIO, ONUFRIO, a voluminous Italian antiquary and historian, was born at Verona in 1529. A love for the records of former times early became his master-passion and gave the bent to his entire career. That he might enjoy both time and opportunities for study, he became a monk of the order of St Augustine, and in that capacity went to receive his education at Rome. The appointment to a theological chair at Florence did not divert him from his favourite pursuits, for he soon obtained from his superiors leave to resign. He then made an antiquarian tour through Italy, rummaging the archives in the principal cities, and collecting information touching the dates of events and the customs of nations from the inscriptions on medals, monuments, and other relics of antiquity. This course of preparatory study was followed by a period which was spent in the midst of literary quiet, and under the smile of liberal patrons. In 1555 Pope Marcellus II. encouraged him in his studies, and gave him a situation in the library of the Vatican. On the death of that pontiff immediately afterwards, he was received into the family of Cardinal Farnese. He was daily obtaining other marks of his patron's esteem, when he was cut off in 1568, at the age of thirty-nine. Panvinio left many erudite works behind him. Among the most important are the following:—

Epitome Pontificum Romanorum usque ad Paulum IV., fol., Venice, 1557; *Viginti-Septem Pontificum Romanorum Elogia et Imagines*, fol., Rome, 1568; *Fasti et Triumphi Romanorum a Romulo usque ad Carolum V.*, Venice, 1557; *De Ludis Secularibus et Antiquis Romanorum Nominibus*, fol., Heidelberg, 1588; *De Baptismate, Pascali Origine, et Ritu Consecrandi Agnos Dei*, 4to, Rome 1560; *De Sybillis et Carminibus Sybillinis*, 8vo, Venice, 1567; *De Triumpho Commentarius*, fol., Rome, 1573, and 4to, Helmstadt, 1676; *De Ritu Sepeliendi Mortuos apud Veteres Christianos et Eorum Cœmeteriis*, 8vo, Louvain, 1572, and 8vo, Rome, 1581; *De Republica Romana*, 8vo, Venice, 1581; *De Bibliotheca Pontificis Vaticana*, 4to, Tarragona, 1587; *De Ludis Circensibus Libri Duo et De Triumphis Liber Unus*, fol., Venice, 1600; *Amplissimi Ornatissimique Triumphi ex Antiquissimis Lapidum Nummorum Monumentis, &c, Descriptio*, fol., Rome, 1618; and *De Antiquitate et Viris Illustribus Veronæ Libri Octo*, fol., Padua, 1648.

PAOLA, or PAULA, a town of Naples, province of Calabria Citra, stands on a height at the edge of a deep ravine not far from the sea, 13 miles W.N.W. of Cosenza. Many of the houses are well built; and there are a castle and two forts. It contains several convents, hospitals, silk factories, and a pottery. The fisheries are extensive. Pop. 5500.

PAOLI, PASQUALE, a great patriot and legislator, was the younger son of Giacinto Paoli, and was born at the village of Rostino in Corsica in 1726. His training was such as became one who was destined to be a great benefactor to his country. Born in a family of patriots, and at a time when the Corsicans were struggling for independence, the young boy imbibed with his opening faculties a strong love of freedom. Then removing at the age of fourteen with his exiled father to Naples, he received the most thorough discipline which that city could give. In the school of Genovesi, the eminent political economist, he learned humanistic philosophy; in the Neapolitan army he became acquainted with military tactics; and in the pages of his favourite classical authors he caught the spirit which animated the great citizens of antiquity. Thus prepared with the high accomplishments of a ruler, Paoli, in 1755, was summoned by his fellow-countrymen to be their general, and he immediately entered upon the great work of his life. It now became his task to reform a people, rude, unlettered, torn by hereditary feuds, living under wild sword-law, and exasperated by a long-continued struggle for liberty. His first measure was to reconcile them to authority. For this purpose, wandering forth among them, he brought all the qualities of his noble nature into play. His graceful and princely bearing won their hearts, his gentle eloquence captivated their understandings, and his calm energy of character awed them into submission. Paoli's next endeavour was to organize a government. Accordingly, he brought into operation a democratic administration at once simple and self-sufficient. The citizens above the age of twenty-five elected a legislative assembly called the *Consulta;* the *Consulta* nominated out of its members an executive body called the Supreme Council; and the Supreme Council acknowledged the general of the nation as its president. Any contested judicial sentence was referred to a censorship of five; and any abuse of power was punished by a decree of the people. Having established law and order, Paoli next employed the influence of the government to bring the nation under the agencies of civilization. Agriculture was promoted; manufactories were put in motion; a national printing-press was instituted; and on the 3d January 1765 a Corsican university was opened. Paoli now began to see the results of his legislation. As the Corsicans grew wealthier and more enlightened, they became stronger and more inspirited. A militia which they organized beat back the Genoese from the interior of the island, and hemmed them in within a few seaport-towns. A fleet which they built took up the offensive against their foes, and captured in 1767 the island of Capraja. At the same time, they were becoming devotedly attached to the civil administration. Their general was regarded as the saviour of his country. As he walked out among his people, old men blessed him, and women held up their children to see the man who had made the nation happy. This fair fabric of prosperity which Paoli was rearing was not, however, destined to be completed. On the 15th of May 1768 the Genoese, having lost all hope of ever re-conquering Corsica, sold their right over the island to the French. The small nation of the Corsicans, just emerging from barbarism, was thus involved in a losing struggle with one of the great powers of the earth. In vain did the natives for some time with desperate valour check the advance of the forces under Marbœuf and Chauvelin: in vain did they rout the invaders at the bridge of Golo and at Borgo. A reinforced army, under a new general, De Vaux, advanced against them in the beginning of 1769. After a struggle of three days, they were driven from their camp at Murati; and on the 9th May of that year their cause was irretrievably ruined by the decisive battle of Ponte Nuovo. The wise magnanimity of Pasquale Paoli now appeared in greater prominence than ever. Unlike the old tragic heroes, he thought it better, in a contest with destiny, to give way for a little, and remain upon guard, than to offer an unyielding resistance, and be crushed beneath her inevitable blow. His first step, therefore, was to leave the island and retire to Leghorn. Then, finding refuge in England, he lived for twenty years in London, taking no

part in the political intrigues of the day, keeping a thoughtful silence, and waiting for an opportunity to benefit his enslaved country. At length the events of the French Revolution restored Paoli to Corsica, and to an important place in its administration. At first he acted as lieutenant-general and military commandant of the island under the government of France. Then, becoming shocked with the lawless and sanguinary procedure of the Convention in Paris, he organized an anti-French party, and called in the assistance of the English. His cause was victorious; the garrisons of France were driven out of the island; and in 1794 Corsica, with the consent of the natives, was united to Great Britain. The reward which Paoli received for these services was little more than neglect. The office of viceroy of the country, which should have been conferred on him, was conferred upon Sir Gilbert Eliot. He was even prevented, for reasons of state, from passing the closing years of his life in the fatherland he had loved so well. He was called to England in 1795, and died there on the 5th February 1807.

Paoli, *Clemens*, the elder brother of the preceding, was born in 1715, and, like the rest of his family, began at an early age to take an active part in the struggles of his country. His character was that of a saintly hero of the old Hebrew type,—fervent in prayer and mighty in battle. Although he was one of the Corsican generals, and although he might have held a high office in the government of his brother, he preferred to assume the garb of a monk and the uniform of a common soldier. To fight and to pray became the sole desires of his heart. At the sound of the coming battle he rose from his knees to rush into the field; in the thick of the conflict he fought like a lion, grimly muttering prayers for the souls whom he sent in rapid succession into another world; and when his bloody work was done, he returned to his cell with a pious countenance to resume his interrupted devotions. Thus did this praying soldier in the wars of the Corsicans become the champion of the national cause, the chief hero in an army of heroes. It was he who drove the Genoese from the district of Orezza; who carried San Pellegrino and San Fiorenzo; who kept Furiani for fifty-six days, until the village became a heap of ashes around him; who routed the disciplined troops of France at the famous battle of Borgo. Nor, after his country's independence had been lost on the fatal day of Ponte Nuovo, did his holy valour suffer abatement. Retiring to a solitary cloister near "the brooks of Vallombrosa," he continued for twenty years to pray and wait for the hour when he might draw his sword once more in Corsica's behalf. He had returned to the island an aged man, yet anxious to play a part in the restoration of national freedom, when he died in 1793 in the convent of his native Rostino. (*Wanderings in Corsica*, translated from the German of Gregorovius by Alexander Muir, in 2 vols., Edinburgh, 1855; and Boswell's *Account of Corsica*.)

PAOLO VERONESE. See Cagliari.

PAOU, Tacanova, or Sandalwood, one of the Feejee Islands, in the Pacific Ocean, S. Lat. 17., W. Long. 179.; length, 96 miles; average breadth, 25. Its outline is irregular, and its surface hilly, containing several peaks, one of which, called Corobato, has a height of 2000 feet. Many of the hills are volcanic; and the island is well wooded. The principal product is sandal-wood. Pop. about 15,000.

PAPA, a market-town of Hungary, circle of Veszprim, and 27 miles N.W. of that town. It contains a splendid castle and garden of Count Esterhazy, a fine cathedral, a court-house, convent, and schools. The chief manufactures are china and cloth. Pop. (1851) 12,397.

PAPAL STATES. Under Italy the origin and growth of the temporal power of the Roman pontiffs is taken up. In the article Rome there is sketched a view of the rise and progress of that great state. The present article will be limited to a view of the actual condition of the temporal dominions of the sovereign pontiff.

The *Stato Pontificio*, as the Papal States are called in Italian, is situated in the centre of Italy, being bounded by the Adriatic Sea on the eastern, and the Mediterranean on the western side. It extends in N. Lat. from 41. 9. 8. to 44. 49. 54., and in E. Long. from 10. 26. 2. to 12. 49. 30.; and has an area of 12,041 geographical, or 16,155 English square miles, with a population of 3,124,758 inhabitants. The whole is connected together, with the exception only of the delegation of Benevento, which is surrounded by the Neapolitan province of Principato Ulteriore, and the small state of Pontecorvo, inclosed within the province of Terra di Lavoro, belonging to the same state. The Papal States are bounded on the N.W. by the Lombardo-Venetian kingdom, on the N.E. by the Adriatic Sea, on the S.E. by the kingdom of Naples, on the S.W. by the Mediterranean Sea, and on the W. by the grand-duchy of Tuscany and the duchy of Modena.

The western coast of the States is by far the shortest. It commences a little to the S.E. of Orbitello, in the Tuscan territory, and proceeds by a bay, not deep, to Civitavecchia. It has no towns on the shore; but about 3 miles inland, and visible from the sea, is the small town of Corneto. Civitavecchia is well fortified with good walls and ditches, several half-moon batteries, and various other works; and upon a peninsula is a fine castle, from which a mole is projected, whilst another mole about 180 fathoms in length is carried into the sea. Between these two is the harbour, having 17 feet of water at one of the entrances, and 12 feet at the other. Ships are safe everywhere within the harbour, and have 20 feet of water. Though the principal seaport on this side, Civitavecchia has no great commercial importance, its trade being chiefly confined to the supplies of Rome. In 1856 it was declared a free port. Proceeding to the S.E. of this port, and passing Cape Linaro, a view is obtained of the church of St Peter's at Rome. The miserable villages of Marinella, Palo, and Monterone, about 2 miles from the sea, are visible. The river Tiber has two outlets to the sea, which are divided by the Isola Sacra, a tract of land about 2 miles in breadth and 9 miles in circumference. Of these, the first or northernmost is called the Fiumicino, and the second the Fiumara. All the land near and about the mouths of the Tiber is low and marshy, and not easily distinguished from the sea, which renders the approach dangerous, especially when, as is often the case, it is covered with dense fogs. The Fiumara was the old channel of the Tiber; the Fiumicino, which is now the only navigable mouth, was excavated by Trajan from Porto to the sea, and from him called *Fossa Trajani*. It has a bar at its mouth, with 7 or 8 feet of water, and within it from 2 to 4 fathoms. The Fiumara has only 2 feet of water on its bar, and consequently can be entered by nothing larger than boats. There is good anchorage at from 3 to 6 miles from the shore, where there is a depth of water of from 6 to 13 fathoms, with good holding ground of stiff mud.

From the mouths of the Tiber the land continues low and marshy, and it has no town, but a few houses and towers at intervals; and, like the rest of the Campagna di Roma, of which it forms a part, is frequently so obscured by haze and fog, that the objects on the shore are not easily distinguishable. At the distance of about 30 miles from the Tiber, and 37 miles from Rome, under a projecting headland called Capo d'Anzio, is Porto d'Anzio, the ancient *Antium*, the birthplace of Nero, and one of the most important seaports of imperial Rome. The two moles constructed by Nero, about 30 feet in thickness, one 2700, and the other 1600 feet long, still exist, but the extensive basins they inclosed are now useless except for vessels of

small burthen, owing to the accumulation of sand caused by the filling up in the seventeenth century of the open arches on which the moles were originally built. The papal government has sundry projects for restoring this port, and converting it into a refuge harbour. Two miles E. of Porto d'Anzio is the small dilapidated town of Nettuno, supposed to have derived its name from an ancient temple to Neptune. The whole coast between Porto d'Anzio and Nettuno is covered with vaults, grottoes, baths, pillars, and other remains of Roman villas. At 20 miles from Nettuno is Monte Circello, the *Promontorium Circæum* of the ancients, an isolated perpendicular mass of limestone at the south extremity of the Pontine Marshes. On the S. side of the promontory is the village of San Felice, near to which good anchorage, in 6 or 7 fathoms water, is found; but there is no shelter against winds from the S.E. At 10 miles from thence is Terracina, the ancient *Anxur* of the Volscians, and the last town of the Papal States on the Neapolitan frontier. The harbour, once of celebrity, is now choked up; and the town, though fortified, is inconsiderable. The country around is fruitful, but marshy and unwholesome.

The E. sea-coast of the Papal States, bordering on the Adriatic Sea, extends about 120 miles in length. It commences to the south at the river Tronto (the ancient *Truentus*), by which it is divided from the kingdom of Naples, and extends to the S. mouth of the river Po, where the Lombardo-Venetian kingdom commences. From the Tronto towards the N. there are along the shore a number of small towns and villages, defended by towers, but no harbour or place of shelter, and the coast generally is low and sandy. At a short distance inland, on a hilly range, there are several small flourishing towns, such as Ripatransone, Fermo, Macerata, Recanati, Loreto, and Osimo. About 45 miles from the Tronto, the land trending N. by W. half W., is the city of Ancona, beautifully situated, and spreading like an amphitheatre between the two promontories of Monte Ciriaco and Monte Comero. Its famous port, constructed by the emperor Trajan, and enlarged by Clement XII., who made it a free port to encourage its commerce, is protected by two moles, of which the one erected by Trajan is 2000 feet in length, 100 feet in breadth, and 68 feet in height. On its point there are a battery and a lighthouse, and near it a triumphal arch of white marble, erected in honour of Trajan, and considered as one of the most perfect and imposing monuments of Roman magnificence still existing. The port has a lazaretto, where the quarantine regulations are very strict. The city is defended by several forts and strong fortifications near the harbour and on the heights of Monte Pelago and Monte Cardeto. The harbour of Ancona is the best on the Italian coast of the Adriatic, and vessels may lie in it secure from all winds, as the mole towards its termination has a turn to the west, forming a hook; it is, however, too full of shoals ever to be of consequence as a naval port. Three or four frigates may be well sheltered within the lighthouse, moored by the head and the stern; but in no part of the harbour could ships of that class swing to their anchors. The city is walled, has the best arsenal in the Roman dominions, and carries on considerable trade, arising chiefly from the exportation of corn, wool, and silk. The most appropriate merchant ships for Ancona are those not drawing more than 16 feet of water.

From Ancona to Rimini, a distance of about 50 miles, the coast is of moderate height, and the shore is sandy. The chief towns are Sinigaglia, Fano, Pesaro, and Rimini; but at none of these is there a harbour for shipping. Sinigaglia has only a mole to protect small craft. A great fair is held here, to which many of the Greeks resort, and exchange honey, wax, tar, and other articles, for hemp, wheat, and silk. Fano and Pesaro possess little or no trade, but are ancient places, each furnished with a great number of churches. Rimini is a decayed, but still elegant town, situated in a rich plain between the Rivers Ausa and Marecchia. Near the mouth of the latter river there is good anchorage on muddy ground, in 7 fathoms water; but there is no shelter from the sea-winds. At 4 leagues farther to the north there is good anchorage opposite the town of Cesenatico, a place inhabited for the most part by fishermen. It is connected by a canal with the episcopal town of Cervia, near which there is an extensive plain, used in summer for the production of salt by natural evaporation. On the river Montone, about 5 miles distant from the sea, stands the city of Ravenna, once an important place, and the seat of government, but now fallen into decay, though still possessing several silk manufactories and some commerce. Its port, which is still frequented by the coasting crafts of the Adriatic, is connected with the sea by the Canale Naviglio, 7 miles long, opened in 1737; its entrance is denoted by a beacon or moat, on which a light is hoisted at night. At the tower of Volano is the little port of Goro, the westernmost branch of the river Po, within which ships may enter and be secure in 6 fathoms water; and at that point the Roman territory is terminated by the S. stream of the Po. The alluvial matter of the different branches of that powerful stream has formed numerous shoals, which extend to a considerable distance from the shore, and the bank extends outwards to the distance of 2 leagues. Within the shoals vessels may haul up, and do so occasionally, in from 6 to 10 fathoms water. The mouths of the Po present a figure much resembling those formed by the Mississippi in America. The river, from its source in the Alps, has a course of nearly 380 miles to the sea, and is augmented by many smaller rivers which fall into it, most of its branches being navigable by small vessels. The current is very strong, and its bed having become so elevated that the level of its waters, in the lower part of its course, is several feet above that of the neighbouring lands, great injury has often been done by inundations. To prevent this, strong dykes have been gradually raised on its banks.

On the whole of the eastern coast, which has been here surveyed, there are a great number of small streams running to the sea. They have their source in the range of the Apennines at no great distance, and are consequently of short but rapid course. Many of them are dry, or nearly so, in the summer, at which season the whole district suffers very severely from the want of fresh water.

The surface of the Roman territory, with the exception of those parts on the N. which form part of the valley of Po, and the portion to the S. on the banks of the Tiber, is hilly, and much of it mountainous. The chain of the Apennines, after forming the boundary between the Bolognese and Tuscany, enters the S. part of the Papal States near Borgo San Sepolcro, and runs through them in the direction of N.W. and S.E. much nearer the Adriatic than the Mediterranean Sea, and then is continued through the Neapolitan provinces of the Abruzzi, leaving on their W. slope the Campagna di Roma, in the centre of which the city of Rome stands. From this range of mountains spurs project on both sides, some of them extending to the Mediterranean Sea, and others to the Adriatic; and between these projections are to be found valleys of much beauty, and of the highest degree of fertility. Without any visible communication with this ridge of mountains stand the lofty volcanic range of Monte Cimino, near Viterbo; Monte Santo Oreste (the ancient *Soracte*), a mass of secondary limestone projecting to a height of 2250 feet from the midst of the volcanic tufa of the Campagna; and the volcanic group of Albano, of which Monte Cavo, the highest peak, is 3130, and Rocca di Papa 2648 feet above the level of the sea. The Apennines here are nearly as naked and as

desolate as those in Tuscany and in the vicinity of Genoa, but much more lofty. The Velino, to the N.W. of Rome, rises 8180 feet above the level of the sea; Monte Sibilla, on the border of the Abruzzi, is 7200 feet; and Monte Terminillo is 6998 feet. The great northern plain, which is bounded by the Apennines, the river Po, and the Adriatic Sea, has the same character as the plains of Austrian Lombardy. It is covered with a rich marshy soil, which, near Comacchio, terminates in an almost useless, and always insalubrious swamp. Along the south-western coast extend vast swamps, which are occasionally flooded by the sea. They are scarcely habitable, though sometimes shepherds resort to them. The pestilential air causes them to be avoided. These districts, from the mouth of the river Astura to Terracina, contain the Pontine Marshes, which neither the emperors of ancient, nor the popes of modern Rome have been able to render of any real value. What Pope Pius VI. performed has been of no great avail, though it has produced a certain improvement, and has enabled some tracts of them to be changed into rich pastures.

The Mediterranean Sea receives the water of but one considerable river in the Papal States. The celebrated Tiber rises in the Apennines, under Monte Coronaro, below the village of Le Balze, in the duchy of Tuscany, enters the Roman territory at the town of Borgo San Sepolcro, and taking a south-westerly direction, and passing through Rome, after a course of nearly 250 miles, during which it receives forty tributary streams, falls into the sea at Ostia. It is only navigable for the last 15 miles between the metropolis and its mouth. The principal river of the Roman States is that which forms one of its boundaries, the Po. From the Roman States its water is augmented by the streams of the Panaro, the Reno, the Riolo, the Porotto, the Idice, the Santerno, the Senio, and the Lamone. These various streams are for the most part united by canals, and rendered navigable; and they also greatly contribute to cultivation by affording easy means of irrigating the fields near them. Besides the Po, the other principal streams which empty themselves into the Adriatic from the Papal Territory are,—the Montone, which runs into the sea near Ravenna; the Savio, which empties itself S. of it; the Uso, a small stream near Forli, which Benedict XIV., by a papal bull, decided, in 1756, was the Rubicon, though the arguments preponderate in favour of the Fiumicino or Pisatello, a small stream near it, as that at which Julius Cæsar hesitated; the Metauro, which runs by Fano; the Foglio, near Pesaro; the Musone, the Leta, the Asone, and the Tronto, which last forms the boundary between the Roman States and the territory of Naples.

There are several lakes in the Papal States. The largest of these is that of Perugia (the ancient *Thrasimenus*), celebrated for the victory obtained upon its banks by Hannibal over the Romans. It is nearly 30 miles in circumference, is surrounded by gentle eminences covered with oak and pines, and contains three small islands. Its greatest depth is 21 feet. It is well stored with fish, and the outlet is into the Tiber. The Lake of Bolsena (the ancient *Vulsiniensis*), near the town of that name, is about 26 miles in circumference, and has two small islands. Its shores are deserted in consequence of the most fatal malaria. The Lake of Bracciano (the ancient *Sabatinus*), near the town of that name, is 20 miles in circumference. Besides these lakes, there are many smaller, such as the Lake of Vico (the *Ciminus* of the ancients), 3 miles in circumference; the charming lakes of Albano and of Nemi, in the vicinity of Rome; the Lake of Piè di Luco, near Rieti; &c.

The mountainous parts of this territory abound in mineral springs of various degrees of medicinal celebrity. Those most frequented are,—the acid springs near Rome; the baths of Bracciano; the baths of Stigliano, near Tolfa; the baths of Palazzi, near Civitavecchia; the warm baths and acid springs of the Bulicame, between Montefiascone and Viterbo; the baths of La Porretta, 32 miles from Bologna, on the road to Florence by Pistoia, &c.

The climate of the Ecclesiastical States varies much according to the local position of the several parts. Some of those produce the orange in perfection, whilst others are covered with snow during great part of the year. The tops of the Apennines are clothed with snow in October, and it generally remains till May. The northern part, in the valley of the Po, has the climate of Lombardy, and the environs of Rome that of Naples. At Terracina the gardens are inclosed with fences formed by the aloe. The heat is tempered by breezes from the sea. The air upon and between the Apennines is generally favourable to health; but on the Pontine Marshes, and near the mouths of the Po, as well as near to Rimini, the marshes are gradually extending, and their pestiferous influence is observable in the increase of dense fogs, and the diminution of the population.

The description of the agriculture of Lombardy, given under that head in the present work, will apply to the portion of the territory of the Church near the Po, in the four legations of Bologna, Ferrara, Ravenna, and Forli. In the other parts the art is most negligently exercised, as well in the Apennines as in the plains of Rome itself. The Roman States produce a sufficiency of corn for their own consumption; and, in ordinary years, even for exportation. Wheat, maize, and barley, are the chief grain; but the great mass of the poorer people eat but little bread, and, especially in the Apennines, substitute for it chesnuts, onions, and beans. A great part of their food consists of fruits, culinary vegetables, and salads. They rarely taste animal food, except a little bacon or sausages. Flax and hemp are raised in great quantities to supply the inhabitants, and for exportation. Saffron is also produced to a considerable extent, and is an article of export. Some cotton is raised, and the growth of it is rapidly extending. In some parts many plants are raised that are applied by the perfumers to their preparations, such as spikenard, anise, and others. The olive grows everywhere, but is almost exclusively reserved for home consumption.

Vines are generally cultivated, but their management is careless, and the selection of the kinds of them very negligent and injudicious. The best wine is made about Montefiascone, Orvieto, and Albano; but the greater part of the common wine is very indifferent. Some little of a moderate quality is made about Bologna and Ravenna, part of which finds a market in Venice. The land produces a great variety of fruits. In the plain of Rome oranges, citrons, pomegranates, and figs ripen; and amongst the Apennines there is an abundance of almonds, walnuts, and chesnuts. The forests produce wood for fuel, and some little is sent to the Isle of Elba to supply the iron-works. On several parts of the coast much soda is prepared. The woods of Terracina have many cork-trees, the bark of which forms an article of foreign commerce.

Formerly the breeding of horses was carefully attended to, but of late it has been negligently pursued; and the celebrated race known by the name of Borghese has deteriorated, and nearly disappeared. On the Apennines asses and mules are used as beasts of burden and for riding; and for the plough, oxen are almost universally employed. The breed of cows is very fine; and they roam about the Campagna di Roma almost without attendance. The milk is not converted into cheese or butter, but the profit they yield to the proprietors, some of whom have herds of nearly two thousand, arises from the sale of the calves, and of the mothers when fattened. Sheep are very numerous, especially on the shores of the Mediterranean. There are two distinct races. One of these, called *negretti*, are small, with very strong and very white wool, as fine as that of Aragon, whence the race, as well as the name they bear, has been

derived. They give abundance of milk, from which much cheese is made. These flocks, like their ancestors in Spain, are migratory. In the month of May they march from the plains near Rome to the mountains of Norcia and the Abruzzi, and return again in October. The other race of sheep, called *puglia*, are inferior in their wool, and are stationary on the Apennines and the lands situated on the Adriatic shore. Goats are very numerous, both on the plains and on the Apennines. They yield abundance of milk, which is converted into cheese; but much of it serves to sustain the swine, of which large herds are bred and fattened upon some of the most extensive farms. The production of silk is one of the most important objects in Roman agriculture, and gives occupation to almost every member of certain families for the season. The soil is favourable to the growth of the white mulberry, the leaves of which yield the finest silk; that of the best quality, collected near Fossombrone, is chiefly exported to England and Germany.

The manufacturing operations of the Ecclesiastical States are very limited, and chiefly adapted to domestic consumption. The chief seat of the silk manufactory is Bologna, which formerly had the monopoly of the trade in crapes, but now divides it with the fabrics of other parts of Europe. Linen and woollen cloths are made, some good paper is produced, and leather is made in several parts; also glass, pottery, rosaries from Loretto, artificial flowers, tallow, and wax candles, with a variety of small articles.

There are no mines worked within the Roman territory, but considerable quantities of excellent alum and of sulphur are furnished, and some saltpetre; and on the coast there are lagunes, from which culinary salt is made by the natural evaporation of the sun's rays.

The Papal States are divided into twenty provinces, the first of which is the Comarca of Rome, which includes within its jurisdiction the Capital and the Agro Romano, and is governed by a president, who is always a cardinal. The other nineteen provinces are divided into *Legations*, which are governed by cardinals, though of late years this rule has not been strictly adhered to, and *Delegations*, governed by prelates, who are styled *Monsignori*. Each legation or delegation is divided into districts, each district into governorships, and these into communes. The following table will show the extent and population of each province, as well as of its capital, according to the official returns of the last census, completed in 1853:—

Provinces.		Area in geographical square miles.	Population of each Province. In 1816.	In 1833.	In 1844.	In 1853. In Towns.	In Country.	Total.	Average per sq mile.	Number of Houses.	Population of the capital of the province.

The annexed table, showing the sex and the various ages of the population, will give an idea of the comparative longevity in the Papal States:—

Ages.	Males.	Females.	Total.
Under 5 years	184,175	171,986	356,161
From 5 to 10 years	181,028	168,819	349,847
„ 10 to 20 „	308,057	285,396	593,453
„ 20 to 30 „	281,786	265,901	547,687
„ 30 to 40 „	219,726	208,871	428,597
„ 40 to 50 „	173,352	170,137	343,489
„ 50 to 60 „	120,287	122,571	242,858
„ 60 to 70 „	86,417	89,519	175,936
„ 70 to 80 „	37,127	35,173	72,300
„ 80 to 90 „	6,679	6,031	12,710
„ 90 to 95 „	287	296	583
„ 95 to 100 „	56	62	118
Upwards of 100 „	11	8	19
Total	1,599,988	1,524,770	3,123,758

The population was grouped in 608,280 families, each of an average number of 5·14 members, nearly one-half of them living in towns, and the other half in the country; but commerce and manufactures are so insignificant that many of the inhabitants of the towns also are more or less dependent upon agriculture. The subjoined table, showing the value of the total yearly imports and exports, as well as of some of the principal articles, from 1850 to 1853, will give an idea of the chief produce of agriculture, as well as of the state of the manufactures of the country.

The foreign trade of the States, which is not considerable as compared with their extent of coast both on the Adriatic and the Mediterranean, is chiefly carried on at Ancona, but varies much in different years. Thus, the number of vessels of various nations which entered that port in 1854 was 1421, of 80,612 tons; in 1855 it was 941, of 76,002 tons; in 1856, 1296, of 121,691 tons; and in 1857, 684, of 110,704 tons. The vessels that cleared it were,—1274 in 1854, 919 in 1855, 1259 in 1856, and 652, of 104,786 tons, in 1857.

Value of Principal Articles, and Total of each Year.

The government of the Papal States is an unlimited elective hierarchy, presided over by the Pope, and administered by a Council of Ministers, of whom the Cardinal secretary of state and of foreign affairs is the chief and most influential member. The other ministers,—interior, grace and justice, finance, war, police and commerce, public works and fine arts,—though they may be laymen, are generally ecclesiastics or prelates. The latter are a class peculiar to the Papal States. Any one who has passed the degree of Doctor of Laws, and enjoys a small independent income, may be admitted into the *Prelatura*, which entitles to employment in the Pope's household, and in the various departments of the state, and is the stepping-stone to preferment to most of the highest offices,—such as nuncio, delegate, governor of Rome, &c., and possibly even cardinal. The *prelate* wears a peculiar costume, is styled *Monsignore*, though he is neither a bishop nor necessarily an ecclesiastic, and is bound by celibacy as long as he retains office. If not in holy orders, on retiring from office, he becomes a layman, and may marry. The election of the Pope originally rested with all the clergy and the people of Rome; it was made, as Anastasius Bibliothecarius tells us, "*A cunctis sacerdotibus seu proceribus, et omni clero nec non et optimatibus, vel populo cuncto Romano.*" Before his consecration the new Pope had to receive the imperial sanction, and, by a decree of the Emperor Otho I., had to swear to respect the rights of the clergy, of the people, and of the emperor. In the year 1059 a great change was introduced by Pope Nicholas II., who vested the College of Cardinals with the exclusive right of electing the Pope out of their own body. Eventually, and after a long contest, not only the Popes emancipated themselves from any imperial sanction to their election, but, under Gregory VII., the church asserted its pre-eminence over the empire.

On the death of a Pope, and till his funeral on the ninth day, the supreme power of the state is in the hands of the Cardinal *Camerlengo*, who, during that time, has even the privilege of coining money bearing his own name and arms. On the tenth day the cardinals are to meet in secret Conclave, and by secret voting, and a majority of two-thirds of their number, appoint a successor

The number of cardinals, who at first were the parish priests of Rome (*parochi cardinales*), was limited to seventy by Sixtus V. in 1586, in allusion to the number of disciples commissioned by our Lord to preach the Gospel. They constitute the Sacred College, are appointed for their lifetime by the Pope, and are designated as Princes of the Church. They rank in six classes,—*1st*, Six cardinal bishops of the suburban dioceses of Ostia (Velletri), Porto (Civitavecchia), Sabina, Palestrina, Albano, and Frascati; *2d*, Fifty cardinal priests; *3d*, Fourteen cardinal deacons. Their part in the government and in decisions alike on spiritual and temporal affairs, and their share in the revenues of the church, were agreed upon in the conclave that was held after the death of Martin V., and were framed in nine articles ratified after his election by Eugene IV. in 1431, which may be called the *Magna Charta* of the Sacred College.

In the Papal States, exclusive of Rome, there are nine archbishoprics and fifty-two bishoprics. The archiepiscopal sees are Bologna, Ravenna, Ferrara, Spoleto, Fermo, Camerino, Bevagna, Urbino, and Benevento. The inhabitants all adhere to the Roman Catholic religion, with the exception of about 12,500 Jews, who reside at Rome, Ancona, and Ferrara, and have eight synagogues. At Rome they are compelled to live in a separate confined quarter, called the *Ghetto.* The clergy is very numerous—21,415 monks and friars, occupying 1800 monasteries; and 16,905 priests; forming a total of 38,200, or more than one for every 82 inhabitants. There are, besides, about 8000 nuns, with 600 nunneries. In Rome alone there are nearly 4500 priests, monks, and friars, and 1800 nuns.

The education of the people is very little attended to, and, with the exception of the kingdom of the Two Sicilies, the instruction of the lower classes in reading and writing is less spread than in any other part of Italy. In all the communes that can afford it there are schools for primary education, under the superintendence of the parish priest: the teachers, always ecclesiastics, are appointed by the communal council. In the episcopal towns there are the bishops' schools, for the education of persons intended for the church. For the higher branches of knowledge there

Papenburg.

are eight universities, two primary and six secondary ones. The primary are,—the Sapienza at Rome, founded in 1244; and the university of Bologna, which dates from 1119. The secondary universities are those of Ferrara (1264), Perugia (1307), Macerata (1548), Fermo (1589), Camerino (1727), and the Gregoriana, or Collegio Romano, at Rome itself. The number of young men who receive in them an academical education is reckoned at about 3400. The education of women is greatly neglected, and the little education they receive is almost entirely acquired in convents.

The *Corpus Juris* and the *Jus Canonicum*, or the civil law and the canon law, and a *Motu Proprio* of July 10, 1831, by Gregory XVI., are the texts by which justice is imparted in the Papal States. The judges are appointed by the Pope, and are removeable. There are tribunals of first instance in the capital of every province, and courts of appeal at Bologna, Macerata, and Rome. Over the latter is the Corte della Segnatura, sitting at Rome, which resembles the French Cour de Cassation. It revises the judgments of the courts of appeal, and in case of any violation of the law, annuls them, and sends the parties before another court for a new trial. At Ancona, and in the other principal towns, there are tribunals of commerce, to decide commercial cases. When an ecclesiastic, however, is concerned in a lawsuit, the jurisdiction belongs to the bishop's court, from whose judgment an appeal may be interposed to the court of the metropolitan. In all the courts the proceedings are public, except in state trials, which are brought before the *Consulta*, a secret tribunal, in which the prisoner is allowed neither to see the witnesses nor to have communicated to him the nature of the evidence to be adduced; and he can only be defended by the official advocate of the Consulta. The Vicario's court at Rome, and the bishop's courts in the provinces, have arbitrary powers summarily to imprison any person of either sex on the grounds of immorality; a power which often leads to acts of great injustice.

The whole military force of the Papal States in 1857 amounted to 16,900 infantry, and 1315 cavalry. It consisted of two Swiss regiments, two regiments of Italian infantry, a battalion of chasseurs de Vincennes, one regiment of dragoons, one of artillery, a corps of military engineers, the Pope's noble guard of 80 noblemen, the Swiss body-guard (126 in number), 4540 gend'armes, and 1760 custom-house guards. The principal fortresses are, Ancona, Ferrara, Civitavecchia, and Castel St Angelo, in Rome, of which the two former are now held by the Austrians, and the two latter by the French. A gun-brig, two steamboats, and some small craft, form all the Papal navy.

The finances of the country have long been in an embarrassed state. Since 1828 there has been a yearly deficit, which has occasionally been met by an additional loan. According to the official returns lately published by the minister of finance, the revenue of the state, which in 1851 was L.2,269,445, in 1857 had increased to L.3,009,524; but the expenditure, which in 1851 was L.2,621,504, had also swelled to L.3,104,692. From the table we give below of the estimated amount of each branch of the public revenue and expenditure from 1853 to 1857, it will be seen that the expense of collecting the revenue amounts to nearly 25 per cent. on the gross receipts; and that the lotteries, which have a most demoralizing influence, and check the benefit of savings-banks among the lower classes, give the state a net yearly income of only about L.63,000, nearly 75 per cent. of the gross receipts being swallowed up by the machinery of collecting it. It also will be seen that in 1857, 5,076,018 scudi, or more than one-half of the net revenue of 9,716,638 scudi, went to pay the interest on the public debt. The yearly deficit, it must be observed, is greater than that given in the subjoined table, as for the last four years no returns are given of the expenses of the ministry of the interior and the ministry of police.

The only railway as yet constructed in the Roman States is the short line of 10 miles from Rome to Frascati, which was opened in 1856. Another line from Rome to Civitavecchia is not yet (1858) completed. (* * *)

PAPENBURG, a town of Hanover, in the government of Osnabrück, near the left bank of the Ems, 23 miles S.S.E. of Emden. It contains distilleries, saw-mills, and manufactories of sail-cloth. Many ships are built here; and an active trade is carried on. Pop. (1852), including the village of Drostensyhl, 5641.

PAPER.

Paper. PAPER is a word derived from the Greek πάπυρος, *papyrus*, the name applied to the celebrated Egyptian plant which was so much used by the ancients in all kinds of writing. It is unnecessary to describe the different expedients which men have, in every age and country, employed for giving permanence to their ideas, and handing them down to posterity. When the art of writing was once discovered, stones, bricks, leather, stuccoed cloth, potsherds, leaves of trees, the outer and inner bark, plates of lead, wood, wax, and ivory, were all employed. Among the curious miscellaneous relics of ancient Egypt which have come down to us, are fragments of pottery inscribed with various documents, as soldiers' furloughs, orders of admission, memoranda, accounts, &c. In the progress of society men have tried other more permanent devices for this purpose, and have successively invented the Egyptian paper, paper made of cotton, paper manufactured from the bark of trees, and in our times paper prepared from old rags.

The only kinds of paper which merit particular attention are,—*first*, the Egyptian; *secondly*, that made from cotton; *thirdly*, paper made from the interior bark of trees; *fourthly*, Chinese paper; *fifthly*, Japanese paper; *sixthly*, paper made from asbestos; and, *lastly*, paper prepared from linen and cotton rags.

Egyptian paper.

Egyptian paper, so called from its having been used by the ancient Egyptians, was made from a species of reed called *papyrus*, which grew on the banks of the Nile. The ancient botanists placed the papyrus amongst the gramineous plants, or dog-grass. Ignorant of the particular kind to which it belonged, they were contented to specify it under the name of *papyrus*, of which there were two kinds, namely, that of Egypt, and that of Sicily. The papyrus (*Papyrus Niloticus; Papyrus Ægyptiacus; Papyrus antiquorum; Papyrus antiquorum Niloticus*) is of the order *Triandria Digynia*, and is one of the many varieties of the genus *Cyperus*. The stem is naked, and reaches a height of ten and even fifteen feet. It is surmounted by a plume of leaves and flowers. Besides its well-known seat in Egypt, the papyrus, in several varieties, has been observed in Syria, Sicily, Calabria, India, and Madagascar. The name *papyrus* was probably but the Greek transcript of the native name of the plant, *babeer;* but the same plant was also known to the Greeks under several other names, as βύβλος, βίβλος, and, more rarely, δέλτος, from the chief seat of its cultivation, the delta of the Nile. Considerable uncertainty has prevailed, nevertheless, among modern botanists, as to the exact identification of the plant formerly used in Egypt for the manufacture of paper. Many have supposed that some alteration of the soil of Egypt, or in the system of cultivating the plant, may have induced such modifications of its appearance as to render it difficult of recognition; and it has even been suggested that it may have disappeared altogether in the long series of ages, and the many social and political revolutions through which Egypt has passed since the classic times.

Whatever doubts may have formerly existed on this point are now at an end. Bruce not only saw the papyrus growing both in Egypt and Abyssinia, but actually made paper of it, in the same manner as that in which it was made by the ancients. He tells us, likewise, that, so far from any part of it being useless, the papyrus is at this day used in Abyssinia for making boats; a piece of the acacia tree being put into the bottom to serve as a keel. That the boats of ancient Egypt were made of a species of papyrus, probably of the very same construction described by Bruce, we know from the testimony of Pliny, who informs us that the plants were first sewed together, and then gathered up at stem and stern, and tied fast to the keel: *Conseritur bibula Memphitis cymba papyro.* It is not by any means clear, however, that the plant which Bruce found in use for the manufacture of boats is the same which he made into paper; and perhaps, indeed, a good deal of the difficulty among modern botanists has arisen from their not observing that more than one variety of the Cyperus appears to have been turned to different uses by the Egyptians; to some of which uses—as the making of baskets, mats, sandals, sails, and even punts or boats—the Cyperus used in paper-making appears but little suited, or rather, in which it could not be so profitably employed. Now, Sir Gardner Wilkinson mentions two varieties which are still common in Egypt—the *Cyperus dives* and the *Cyperus papyrus.* The former, which is even yet cultivated for many of the uses specified above, he thinks to have been that used by the ancients for boats and for all the other coarse manufactures. The *Cyperus papyrus* (the *Papyrus hieraticus* of Strabo, and the *berd* of modern Egypt) was reserved chiefly for the manufacture of paper.

Another question has arisen among modern botanists, whether the papyrus of Sicily is the same with that of Egypt, and whether the Romans used the former plant for the purpose of paper-making, or for any other of the uses of the Egyptian papyrus. The Sicilian plant is called in Italy *papero*, or *pipero.* A careful examination of it was made by the celebrated naturalist, Cesalpino, for the purpose of resolving this question. His opinion was, that the two plants, although bearing a strong resemblance to each other, were in reality different. The papyrus of Sicily, says he, which is there commonly called *pipero*, has a longer and thicker stem than the plant cyperus. It rises sometimes to the height of four cubits; the angles are obtuse, and the stem at the base is surrounded with leaves growing from the root; and there are no leaves on the stem, even when the plant is at its greatest perfection, but it carries at the top a large plume, which resembles a great tuft of dishevelled hairs. This is composed of a great number of triangular pedicles, in the form of reeds, at the extremity of which are placed the flowers, between two small leaves of a reddish colour like the cyperus. The roots are woody, about the thickness of reeds, jointed, and throw out a great number of branches, which extend themselves in an oblique direction. These are scented somewhat like the cyperus, but their colour is a lighter brown. From the lower part issue many small fibres, and from the higher a number of stems shoot up, which, in proportion as they are tender, contain a sweet juice.

An interesting description of the Sicilian plant, accompanied by elaborate drawings, was written by Doctor Domenico Cirillo, and published at the celebrated Bodoni press at Parma, in which the habitat, form, and characteristics of the Sicilian plant are minutely described, and contrasted with those of the Egyptian papyrus, as detailed by Pliny, Prosper Alpinus, Bauhin, and others. Cirillo's own conclusion from the comparison is, that the Sicilian is exceedingly like (*simillimam*) the Egyptian plant, as described by Theophrastus and Pliny. (*Domenici Cyrilli, Medicinæ Doctoris, Cyperus Papyrus*, folio, Parma, 1796, p. x.)

The accuracy of this judgment was impugned by some of the botanists of the last century. But later researches have tended to confirm the authority of the older naturalist. It is certain that the ancients themselves recognised the same character of resemblance between two varieties of the plant which they regarded as distinct. Theophrastus (*Histor. Plantarum*, iv. 8.) distinguishes the *sari* (σάρι) and the *papyrus* (πάπυρος); observing that, although

they have a decided character of resemblance, they differ in this, that the papyrus sends forth thick and tall stems, which being divided into slender plates, are fit for the fabrication of paper, whilst the sari has small stems, considerably shorter, and altogether useless for any kind of paper.

The papyrus, therefore, which anciently served to make paper, must not be confounded with the papyrus of Sicily, which is also found in Calabria. According to Strabo, the former was not to be found anywhere except in Egypt and in India. The greater part of botanists have believed that the Sicilian plant is the same with the sari of Theophrastus; but others have alleged that the papyrus of Egypt and the sari were the same plant in two different stages of its existence, or considered with respect to the greater or less height; which, according to them, might depend upon the qualities of the soil, the difference of the climate, or other accidental causes. In proof of this, it is maintained, that there is an essential difference between the papyrus growing in the waters and the same plant growing on the banks of rivers and in marshes. The first of these has thick and tall stems, and a plume in the form of a tuft of hair, very long and slender, and without any seed. The second differs from the first in all these particulars; it has a shorter and more slender stem, its plume is loaded with flowers, and consequently it produces seed. In whatever way we consider these facts, it is sufficient for us to know, that the difference between the papyrus and the sari neither depends on climate, nor soil, nor situation. The plants, whose difference depended on these circumstances, both grew in Egypt, and were both employed in the manufacture of paper. We should add, nevertheless, that, whatever may be the specific differences between the Egyptian and the Sicilian papyrus, the latter may also, absolutely speaking, be converted into paper. Cavaliere Landolina Nava of Syracuse, and others, have actually made paper of it, and sheets of the paper are still offered to travellers as specimens of the manufacture; but they are decidedly inferior in every respect to the ancient Egyptian fabric. (Wilkinson's *Egyptians* iii. 148.) Indeed, not only for the manufacture of paper according to the ancient plan, but in every other industrial point of view, the Sicilian plant appears to be entirely inferior to the kindred one of Egypt.

The *Cyperus papyrus* of the ancients was chiefly cultivated in Lower Egypt, especially in the Sebennitic Nome; and the right of growing and selling it was one of the government monopolies. The date of the origin of the manufacture of paper from this plant has been the subject of much discussion. Pliny, on the authority of Varro, states, that it was unknown in Egypt till the time of Alexander the Great; but there is no doubt that this is a grievous error; and, although it is impossible to fix the precise time at which the use of the papyrus began, modern antiquarians have clearly shown that it dates back as far as the most remote Pharaonic period, to which period many extant papyri are believed to belong. Perhaps, however, the authority of Pliny may at least show that the use of papyrus, especially outside of Egypt, as an article of commerce, became more general after the conquest of Alexander; and on this point Pliny is confirmed by other ancient authors, especially Herodotus (v. 58, ii. 100), Athenæus (xiv. 644), and Theophrastus (*Historia Plantarum*, iv. 8, 4).

The manufacture of the papyrus is minutely described by Pliny (xiii. 23); and, although his account contains some obvious inaccuracies, and has been strangely misunderstood by the commentators in one important point, it is on the whole very interesting. He tells us that "paper is made from the papyrus by splitting it with a needle into very thin leaves, due care being taken that they be as broad as possible." Some of the commentators, and even of the eminent Egyptian antiquarians (among the rest, Sir J. Gardner Wilkinson, iii. 148), understand this to mean that "the interior of the stalks of the plant, after *the rind had been removed*, was *cut into thin slices* in the direction of their length, and these being laid on a flat board in succession, similar slices were placed over them at right angles." Another equally eminent Egyptian scholar, Seyffarth (*Beitrage zur Kenntniss des alten Ægyptiens*, ii. 201), supposes that it was the *stem* of the papyrus which was *cut into slices*. The true explanation of the process, however, is that given by Becker (in his *Charikles*, ii. 220), and indeed follows naturally from the words of Pliny. Neither the pith of the plant, nor the entire stem, if cut into slices, would have furnished a suitable material. But under the coarse exterior rind of the plant lie a number of successive layers of the inner cuticle (*philuræ*), about twenty in number. These several integuments, instead of being sliced, were separated from each other by the point of a needle, and the portions so removed are the "thin leaves" of which Pliny speaks. The best and finest philuræ were those which lay nearest to the centre of the plant, the quality of the others declining as they receded from it. The outer rind or bark was only used for making ropes, and especially for ropes which were to be submerged in water, for which they possessed a remarkable power of resistance. The leaves thus separated were rendered adhesive, not as Pliny states, by the muddy Nile water (which he erroneously supposes to have had certain glutinous qualities), but by the use of a paste made of very fine flour, and mixed with size or glue (for the preparation of which Pliny also furnishes a prescription, ch. 26), and then placed upon a flat board or table, slightly inclined. The leaves were placed down lengthwise, as long as the papyrus would admit of,—forming, as it were, the woof of the fabric,—and their jagged edges were duly cut off at both ends; a second layer of leaves, which may be called the warp, was then laid down transversely upon these at right angles, in the same way, in fact, says Pliny, "that hurdles are made." The leaves were then pressed close, dried in the sun, beaten smooth with a mallet, and polished with ivory, or some similar substance; after which they were all united to each other, the best sheets being always taken first, and the inferior ones afterwards. The sheets were rolled for use upon a cylinder (scapus). The breadth (or depth) of the roll of course was limited by the length of the strips of the papyrus; its length could be indefinitely extended; but Pliny says that they never placed more than twenty sheets on the roll.

The frail specimens of Egyptian paper which have come down to us have created the impression that the ancient papyrus must, like the modern rice-paper, have had the grave defect of exceeding brittleness. But it may be doubted whether this impression is well founded; and very possibly a great deal of this apparent defect of the ancient papyri is rather to be ascribed to the excessive dryness of the climate in which these rolls have been preserved for so many ages, than to their own inherent brittleness. Sir Gardner Wilkinson states, that the best English drawing-paper, after a few years in Egypt, becomes too brittle to fold up without breaking; and that on the contrary, when the papyrus is gradually exposed to steam or to the damp of this climate, it acquires a considerable degree of pliability. He himself mentions one ancient papyrus of Memphis, still extant, which is as pliable as common paper.

The finest quality of the Egyptian paper, that made of the inner leaves, was called *Hieratica*. It was made, as the name implies, by or for the priests, and was not suffered to be sold, lest it should be desecrated by profane writings. But it is curious that, although some writers have denied the existence of palimpsest papyri (see PALIMPSEST), there was a regular trade at Alexandria in Hieratic papyri which had been already written upon, for the purpose of their being washed and re-prepared for a second use. It was only, or at least principally, in this way that, during the time of the Re-

public and in the early days of the Empire, the best papyrus could be obtained in Rome. In later times the manufacture was much improved, and especially after the paper began to be manufactured in Rome. In the reign of Augustus, a very fine quality was produced, which was called *Augusta*, in honour of that emperor. The second quality was called *Liviana*, from his wife Livia, the name *Hieratica* being degraded to the third quality. A still coarser quality was called *Amphitheatrica*, probably from its being made near the amphitheatre of Alexandria; but this kind of paper eventually became a very important article of commerce, from its being used as the basis of a much finer quality, which was manufactured at Rome by a new process. The inventor of this process, who gave his name to the paper (*Fanniana*), was a grammarian of Rome—Q. Remmius Fannius Palæmon—who is supposed to have been Quintilian's preceptor. His process is not described in detail, but it consisted in carefully inserting finer slips into the coarse paper, and probably re-laying or re-adjusting the slips into a closer and smoother fabric. A fifth variety of paper was the *Saitica*, so-called from the city of that name in Lower Egypt, where it was manufactured in large quantities. A sixth kind, *Tæniotic*, called from a place in the vicinity of Alexandria, was made entirely from the coarse exterior layers of the plant, and was sold by weight and not by quality; and a further kind, used only as wrapping-paper, and called *Emporetica* (from ἔμπορος, a merchant), was so coarse as to be quite unfit for writing upon.

The breadth of the paper, which, as we saw, was limited by the length of the strips of the papyrus, was an important element in the value of the different qualities. The *Augustan* paper, according to Pliny, was thirteen fingers in breadth, the *Hieratic*, eleven; the *Fannian*, ten; the *Amphitheatric*, nine; the *Saitic*, still narrower; and the *Emporetic*, only six fingers broad. Pliny adds that the Emperor Claudius made a great improvement in the quality of paper, as to smoothness, colour, and strength. The Augustan paper had been so fine as not to resist sufficiently the action of the sharp point of the pen; and even when it escaped being torn or perforated, the writing, from the extreme thinness of the paper, could be read from the opposite side of the page. To obviate these inconveniences, a sheet of coarser paper was taken as a groundwork, "over which was laid a woof, as it were, formed of leaves of the first quality." In consequence of these improvements, the *Claudian* paper (for so this paper was called) came to be preferred to all others, though the *Augustan* was still used in Pliny's time for all the purposes of correspondence.

Papyrus paper formed an important branch of the commerce of Egypt, which continued to increase towards the end of the Roman republic, and became still more extensive under Augustus. The demand from foreign nations was often so great as to cause a scarcity at Rome; and, in the reign of Tiberius, a tumult occurred amongst the people in consequence of this scarcity. In a letter of the Emperor Hadrian, the preparing of papyrus is mentioned as one of the principal occupations at Alexandria. "In this rich and opulent city," says the emperor, "nobody is seen idle. Some are employed in the manufacture of cloth, some in that of writing paper." During the time of the Antonines, this commerce continued to flourish; and Apuleius says that he wrote upon the paper of Egypt with a reed of the Nile prepared at Memphis.

Towards the end of the third century, the demand for papyrus became so great, that when the tyrant Firmus conquered Egypt, he boasted that he had seized as much paper and size as would support his whole army. St Jerome informs us that it was much in use in the fifth century, when he flourished. The duty on its importation had become excessive towards the end of the fifth or the beginning of the sixth century; and on its being abolished by Theodoric, the Gothic king of Italy, Cassiodorus congratulated the whole world on the cessation of an impost on a merchandise which was so essentially necessary to mankind.

Down to what period papyrus continued to be used, and still more to what date its manufacture continued, it is very hard to determine. Montfaucon and Mabillon mention several fragments written on this paper in the sixth century. One of these was a charter of the Emperor Justinian, entitled *Charta Plenariæ Securitatis*. In 1698, Montfaucon saw, in the library of Giuglio Giustiniani, three or four fragments of Egyptian paper of the same antiquity; and Mabillon mentions a manuscript of the Jewish antiquities of Josephus translated into Latin, which seems to have been written in the same century, and which was preserved in the Ambrosian Library at Milan; but he had not himself seen the manuscripts. The same antiquary mentions his having seen in the library of St Martin of Tours the remains of an old Greek manuscript of Egyptian paper, which appeared to him to be of the seventh century. He also believes that the copy of St Mark's gospel preserved in the Register-house of Venice is written upon the same paper; that it is the most ancient of any of the evangelical manuscripts; and that it may be supposed to have been written, at the latest, in the fourth century. According to the same antiquary, the Egyptian paper was used in France, Italy, and other European countries, both for books of learning and for public records; and there still remain, he adds, a great number of these in the archives of the church at St Denis, at Corbey, in the Abbey de Grasse, and in other convents. That it was also used by the Syrians, Arabians, and other Orientals, is clear from the circumstance that papyri in these languages are still extant. Silvestre, in his *Palæographie Universelle*, gives specimens of more than one.

It is probable that the invention of paper made of cotton, of which we shall afterwards treat, insensibly destroyed the reputation and manufacture of the Egyptian paper; but it is still a question at what particular period the fabrication of the latter totally ceased. Eustathius, the learned commentator on Homer (*Ad. Hom. Odyss.* xxi., p. 1913), assures us that in his time it was no longer in use; but Mabillon maintains that many of the papal bulls were written on papyrus in the eleventh century. Count Maffei, however (*Histor. Diplomat.* lib. ii.; *Biblioth. Ital.* tom. ii., p. 251), is decidedly of opinion that Egyptian paper was not in use in the fifth century. He considers all records written upon this paper, and dated subsequently to this period, as not authentic; and the papal bulls mentioned by Mabillon, as well as the copy of St Mark's gospel, were, according to him, written upon paper manufactured from cotton. On the contrary, Pauly (*Real. Encyclopädie der Klassischen Wissenschaft*, v. 1156) states that a copy of St Augustine's Letters, which Montfaucon saw in the library of St Germain des Prês, partly of papyrus, partly of parchment, is not earlier than the sixth century. To reconcile in some measure these contradictory accounts, it may be observed, that on some particular occasions, and by some particular persons, the Egyptian paper might have been employed for several hundred years after it ceased to be in general use.

Before we pass from the ancient manufacture of the papyrus paper, we may observe, that the plant has been proposed as one of the most promising of the vegetable materials for the manufacture of paper by the modern process. Chevalier Claussen in a paper on "Plants which can furnish Fibre for Paper Pulp," appears to place it higher in the scale, both as regards the per-centage of fibre and the facility of bleaching, than most of the substances hitherto experimented upon. He found it to contain 40 per cent. of strong fibre, excellent for paper, and very easily bleached. He appears to think, however, that the common indigenous rush (*Juncus effusus* and other varieties) will supply an

equally, if not more, available pulp for paper-manufacture.

Paper made from cotton.

It is generally supposed that the invention of the paper called *Charta bombycina* supplanted the Egyptian paper in Greece. This paper is incomparably more lasting, and better calculated for all the purposes of writing. It is not precisely known at what period this art, which supposes a great variety of previous experiments, was first reduced to practice. The application of cotton to the purposes of paper-making requires as much labour and ingenuity as the use of linen rags; and for this reason, if we would determine the precise time when paper was made from cotton, we should also be able to fix the invention of the art of paper-making as it is presently practised in Europe. Montfaucon proves, by incontestible authorities, that paper made from cotton was in use in 1100. This paper in the Greek language is called χαρτη βομβυκινος, or βαμβακινος; for although βομβυξ is the Greek word for silk, yet in those times it was applied, as well as βαμβαξ, to cotton; and hence the Italians call cotton *bambaccio*.

The most ancient manuscript of this paper which Montfaucon saw with a date, was that in the French king's library, written in the year 1050; but as the manuscripts without date are infinitely more numerous than those which are dated, and as some conjecture can be formed concerning them from the manner of the writing, the same antiquary believes that some of these were written in the tenth century. The researches of the same learned person serve to show that this paper was discovered towards the end of the ninth or beginning of the tenth century; for before the twelfth century it was commonly used throughout the eastern empire, and even in Sicily. Roger, King of Sicily, says, in a diploma written in 1145, that he had renewed on parchment a charter which had been written upon cotton paper in the year 1100, and another which was dated in the year 1112. About the same time the Empress Irene, in the statutes for regulating some religious houses at Constantinople, states that she had left three copies of these statutes, two on parchment, and one on cotton paper. From that period paper of this sort became still more in use throughout all the eastern empire; and innumerable Greek manuscripts are found written upon it, in all the great libraries.

This discovery happened at a time when there seems to have been a great scarcity of parchment; for it was about the same period that the Greeks erased the writings of Polybius, Diodorus of Sicily, and many valuable ancient authors, for the sake of the parchment. It was the invention of this cotton paper which destroyed the manufacture of the Egyptian article; for, if we may believe Eustathius, who wrote towards the end of the twelfth century, the latter had gone into disuse but a little before his time. We may easily believe, however, that this new invention, although of great advantage to mankind, was only introduced by degrees.

Paper from the bark of trees.

Paper of the interior bark of trees was made from the white pellicle or inner coat which is found in many trees between the bark and the wood. The trees commonly in use were the maple, the plane-tree, the elm, the beech, the mulberry, and most commonly the linden-tree. The ancients wrote upon this inner coat after they had separated it from the bark, and beaten and dried it. Mabillon and Montfaucon speaks frequently of manuscripts and diplomas written upon paper made from bark; and positively distinguish it from the Egyptian paper, because it was thicker, and composed of parts less adhesive.

There are many palm trees in India and America to which botanists have given the name *papyraceous*, because the natives have written with bodkins either on the leaves or on the bark. Such is the American palm, called *tal* by the Indians; and also the *guajaraba* of New Spain. Every palm, the bark of which is smooth, and the leaves large and thick, may be used for this purpose.

Chinese paper.

The art of making paper from vegetable matter reduced to pulp was known in China long before it was practised in Europe; and the Chinese have carried it to a high degree of perfection. The fine paper of China is much softer and smoother than that of Europe; and these qualities are admirably adapted to the pencil, which the Chinese use in writing. Several kinds of their paper discover the greatest art and ingenuity, and are applied with much advantage to many purposes. These are capable of receiving the impression of types; and Chinese paper is celebrated for affording the most clear and delicate proof-impressions from copperplates.

The different sorts of paper vary in China according to the materials of which they are composed, and the various modes of manufacturing these materials. Every province has its peculiar paper. That of Sechuen is made of linen rags, as in Europe; that of Fo-kien, of young bamboo; that of the northern provinces, of the interior bark of the mulberry; that of the province of Kiang-nan, of the skin which is found in the webs of the silk-worm; and in the province of Houquang, the tree chu or ko-chu furnishes the materials of which paper is made.

The method of fabricating paper from the bark of different trees is nearly the same with that which is followed in the bamboo. To give an idea, therefore, of the manner of manufacturing the interior barks of the mulberry, the elm, and the cotton tree, it will be sufficient to confine our observations to the bamboo.

The bamboo is a kind of cane or hollow reed, divided by knots, but larger, more elastic, and more durable, than any other reed. The whole substance of the bamboo, composed of filaments, and a great abundance of fibrous materials, are employed in this operation. The shoots of one or two years, nearly as thick as a man's leg, are preferred. They strip the leaves from the stem, cut them into pieces of four or five feet in length, make them into parcels, and put them into water to macerate. As soon as they are softened, which generally happens in five days, they are washed in pure water, put into a dry ditch, and covered for some days with lime watered for the purpose of slacking. They are then washed carefully a second time, and every one of the pieces is cut into filaments, which are exposed to the rays of the sun to dry and to bleach. After this they are boiled in large kettles, and then reduced to pulp in mortars of wood, by means of a hammer with a long handle, which the workman moves with his foot.

The pulp being so far prepared, some shoots of a plant named *koteng* are taken, and being steeped in water four or five days, are reduced to an unctuous or glutinous substance; and when the workmen proceed to make the paper, this is mixed with the pulp in certain fixed quantities, because upon this mixture depends the quality of the paper. When the extract from the koteng is mixed with pulp of the bamboo, the whole mixture is beaten together in mortars till it become a thick and viscous liquor; when it is poured into large tubs or reservoirs, so exactly framed as that no part of the liquor can escape. After this the workmen plunge their forms into the liquor, and take out what is sufficient for a sheet of paper, which, when formed and consolidated, is at once dried and detached from the mould, by being held a moment or two against a heated hollow wall, the two fronts of which are smooth and extremely white. At the extremity of this wall is placed a stove, the pipes of which are carried in a circular manner throughout the whole empty space. The sheets of paper are laid on the surface, to which they adhere till a soft brush is applied to them; and after they become dry, it is easy to distinguish the side which received impressions from the brush from that which adhered to the wall. By means of this stove the Chinese dry their paper as fast as they make it; but it is only in cold seasons, or in certain provinces, that they find this expedient necessary.

The Chinese paper must be dipped in a solution of alum before it can take either ink or colour. They call this operation *faner*, from the Chinese word *fan*, which signifies alum. The manner of preparing this solution is extremely simple. Six ounces of isinglass cut very small are put into boiling water, and constantly stirred, that it may dissolve equally. When the isinglass is wholly dissolved in the water, twelve ounces of calcined alum are thrown in, and also stirred till it is completely dissolved and mixed with the isinglass. This composition is afterwards poured into a large deep basin, at the mouth of which there is a little round piece of wood; and the extremity of every sheet of paper is then fixed in another piece of wood, with a slit made to receive it. By means of this apparatus the sheet of paper is plunged into the composition of alum and isinglass; and when it has been fully penetrated by the mixture, it is drawn out, and made to glide over a little round piece of wood. The long piece of wood which holds the sheet by one end, and keeps it from tearing, is afterwards suspended with it on a wall till it becomes sufficiently dry.

The Chinese give to the paper intended for different purposes different colours; but we shall confine our observations to the silver colour, which they impart to some kinds. They take two scruples of paste made of cow's hide, one scruple of alum, and a pint of water, and boil the whole on a slow fire till the water be evaporated. The sheets of paper are then stretched on a smooth table, and covered over with two or three layers of this paste. They afterwards take a certain quantity of talc, washed and boiled in water, with a proportion of one third of alum. The whole is then dried, reduced to a powder, passed through a sieve, boiled a second time in water, dried in the sun, and again passed through the sieve. This powder is then spread equally over the sheets of paper, prepared as above mentioned; and these are afterwards dried slowly in the shade. The sheets of paper, covered in this manner with talc, are laid upon a table, and rubbed with a little cotton, which fixes a certain quantity of talc in the paper, and carries off the surplus to be used on another occasion. By means of this composition the Chinese draw all manner of figures on their paper.

The paper made from the bamboo is sufficiently white, soft, and closely united, without the least inequality on the surface to interrupt the motion of the pencil, or to occasion the rising of the materials which compose it. But every kind of paper made from the bamboo or the bark of trees is more liable to crack than that made in Europe; besides, it is more susceptible of moisture, and is sooner destroyed with dust and worms. To obviate this last inconvenience, people are obliged frequently to beat their books in China, and to expose them to the sun. It may be observed, however, that the Chinese paper, employed for various purposes in Europe, has been preserved for a long time without receiving damage either from moisture or from insects.

Japanese paper.

According to Kæmpfer, the bark of the *Morus papifera sativa*, or true paper-tree, is chiefly employed for making paper in Japan. Every year, after the fall of the leaves, which happens in the tenth month, corresponding to our December, the Japanese cut the young shoots of this tree into pieces of about three feet, and collect them into parcels, which they boil in water containing a certain quantity of ashes. If the wood be dry, they take care to steep it twenty-three hours in water before it is boiled. The parcels are kept in a close copper till the bark at the extremity of the shoots is separated from the stem about half an inch; they are then cooled, and the bark alone is fit for making paper. They begin by a preparation, which consists of cleaning the bark, and separating the good from what is bad. For this purpose they steep it in water three or four hours; and as soon as it is softened they scrape off with a knife whatever is blackish or green, and at the same time separate the strong bark of a year's growth from the slender kind which cover the young shoots. The first of these gives the whitest and best paper. If there be any of the bark of more than a year's growth, it is laid aside for the coarsest kind.
